THE MINERALIZING ACTION OF F^- IONS IN VITROCERAMIC STRUCTURES OF THE $Na_2O-MgO-Al_2O_3-SiO_2$-SYSTEM ON VOLUME EFFECTS

S. SOLACOLU and D. POPESCU-HAŞ
Polytechnical Institute, Chair of Physical Chemistry of Silicates and Oxide Compounds
Str. Polizu, 1, Bucharest, Romania

Received July 24, 1972

Volume effects which occur upon heating a vitreous structure of the $Na_2O-MgO-Al_2O_3-SiO_2$-system using fluorine as a nucleator were investigated. Two plastic deformation areas preceding the appearance of crystalline phases were revealed by the dilatometric curves. The correspondence between temperatures at which plastic deformation areas and those of exothermal peaks on the ATD curves confirms the two stages involved in the formation and crystallization of microphases in vitroceramic masses with fluorine. The difference in the expansion coefficients of masses in various primary structuration compartments shows that structuration is based on the relations of phase heat equilibrium. The predominance of a certain type of structures, in various vitroceramic masses investigated, indicates the selectivity impressed by F^- ions as nucleators on these masses.

1. INTRODUCTION

Both vitreous microphases and crystalline phases occurring in vitroceramic structures obtained by low-temperature crystallization are usually not equilibrium phases and are different from the others found in ceramic masses with the same oxide composition [1,2,3]. They are generally metastable phases and their composition, respectively, the characteristics impressed on vitroceramic masses depend on the heat treatment during crystallization.

Mg^{2+} and Al^{3+} ions in tetrahedral coordination may participate, together with Si^{4+} ions in the formation of vitreous structures [4,5,6] and having larger ionic radius, vitreous structures will be looser or more com-

pact, depending on the larger or smaller number of (MgO_4) (AlO_4) tetrahedra involved in their formation and causing variations in density and in volume.

Our investigations regarding the microstructure of vitroceramic masses of the $Na_2O-MgO-Al_2O_3-SiO_2$ - system showed that the proportion of tetrahedral coordination and penetration of Mg^{2+} and Al^{3+} ions into the composition of solid solutions — the structure of α-quartz appearing as metastable phases in these masses — varies in relation to the MgO and Al_2O_3 content and to the heat treatment during crystallization. [2,3,7]

Taking into account these considerations, the present paper investigates the volume effects obtained on heating certain vitreous structures of the $Na_2O-MgO-Al_2O_3-SiO_2$-system, using fluorine as a nucleator.

2. EXPERIMENTAL APPROACH

The glasses studied were melted in an electric furnace with a platinum-rhodium crucible of own construction. Fluorine-free glasses were melted at a temperature of 1500° for 120 minutes and glasses containing fluorine were melted at 1450° for 60 minutes. Fluorine mixtures were dried prior to melting at 110°, to reduce fluorine losses during the melting process.

The $5 \times 5 \times 50$ mm and $5 \times 5 \times 25$ mm samples were shaped by pressing the melt into metallic moulds and rapidly cooling it thereafter until a temperature of 500° was reached; the cooling rate was then controlled in an electric annealing kiln.

Volume effects were determined by a Leitz—Wetzlar dilatometer.

3. EXPERIMENTAL RESULTS

3.1. VITREOUS STRUCTURES OF THE $Na_2O-MgO-Al_2O_3-SiO_2$ PHASE EQUILIBRIUM SYSTEM

Usually, the melting temperature is of 1500° in glass industry furnaces, hence the compositions of the investigated vitreous structures were placed in the area delimited by the conical projection of the isotherme of 1500° of the $MgO-Al_2O_3-SiO_2$ ternary system in the section corresponding to 10% Na_2O content in the $Na_2O-MgO-Al_2O_3-SiO_2$-system.

Since the $Na_2O-MgO-Al_2O_3-SiO_2$ quaternary system was not investigated, the primary crystallization volumes of components have not yet been delimited; because the 10% Na_2O section is very close to $MgO-Al_2O_3-SiO_2$ ternary system, it was assumed that the position of the compositions investigated in the primary crystallization volumes of the quaternary system corresponds to the primary crystallization compartments of components in the basic ternary system, within the limit of admissible errors.

---

[7] S. Solacolu and D. Popescu-Haş, *Rev. Roumaine Chim.*, **17**, 319 (1972).

Compositions investigated in various primary crystallization compartments presented a same content of SiO_2 while Al_2O_3 and MgO contents varied; the 10% Na_2O content remained constant in all compositions.

The research regarding the volume effects involved in the formation of vitroceramic structures took into account the following objectives:

— occurrence of new phases, structural changes and variation of rheological characteristics during crystallization by heat treatment;

— variation in volume effects in relation to temperature and whether the value of expansion coefficients is similar to the specific value of compounds corresponding to the primary crystallization compartments involving the investigated compositions.

3.2. SYNTHESIS OF VITREOUS STRUCTURES

The raw materials used in the synthesis of the studied glasses were: vein-quartz with a 99.75% 0.1 mm finely-ground SiO_2 content, pure calcinated alumina, magnesium oxide for analysis, sodium carbonate for analysis and pure cryolite.

Mixtures were subjected to gravimetric determination and homogenized in ball-mills. Each mixture was melted three times for homogeneity purposes; specimens were shaped from glasses melted for the third time.

The absence of crystalline phases in the resulting vitreous structures was controlled by X-ray diffraction and by polarized light microscopy.

4. DISCUSSION OF RESULTS

4.1. GLASSES WITHOUT F⁻ ION AS A NUCLEATOR

Figure 1 presents the relative expansion curves of some representative fluorine-free masses denoted by $S_1 - S_7$ symbols whose composition is situated in the primary crystallization compartments of the Na_2O-$-MgO-Al_2O_3-SiO_2$-system.

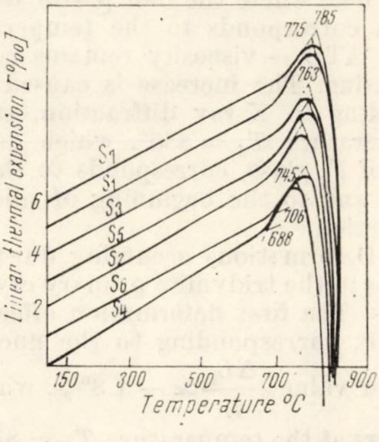

Fig. 1. — Relative expansion curves of fluorine-free glasses of the $Na_2-MgO-Al_2O_3-SiO_2$-system.

The dilatometric curves of investigated fluorine-free glasses are typical for the dilatometric curves of glasses and present three characteristic areas.

The first area corresponds to the practically linear expansion and the average expansion coefficient is $\alpha_{10}^{640} = 7.1 \ldots 8.1 \times 10^{-6}\,°C^{-1}$. The second area corresponds to the so-called dilatometric anomalies due to structural changes occurring in vitreous phase at temperatures ranging between 600°... 720° and 745°... 785°. The third area corresponds to the viscous flow.

4.2. GLASSES WITH F⁻ IONS AS NUCLEATORS

The dilatometric curves of glasses in the $Na_2O-MgO-Al_2O_3-SiO_2$-system with F^--ions as nucleators denoted by $F_1 - F_6$ symbols present inflections that indicate, on the one hand, the variation of rheological characteristics in relation to temperature and, on the other hand, the occurrence of new phases and structural changes producing volume variations.

In general, as temperature increases following plastic deformation effects, viscosity of glasses is lowered to a certain point; it then remains constant for a short period of time called "nucleation" period of crystallization, due to the occurrence of new phases, and starts increasing thereafter. The mass becomes rigid and begins again to expand.

4.2.1. *Volume effects in tridymite masses.* The dilatometric curves of glasses in this primary crystallization compartment compared to ATD curves (fig. 2a) show that, in addition to the temperature corresponding to structural changes in vitreous state, these glasses present four other temperatures which delimit two plastic deformation areas. At temperature $T_2 - 640°$ where the first plastic deformation area ends for F_1 glass — and which corresponds to the temperature of the first exothermic peak on curve ATD — viscosity remains constant for a moment and then starts increasing. The increase is caused by the occurrence of fluorides which, according to X-ray diffraction, start crystallizing at this temperature. Temperature $T_4 = 835°$, which delimits the second plastic deformation area of F_1 glass, corresponds to the second exothermic peak on the ATD curve and to the beginning of silicate crystallization according to X-ray diffraction.

Deformations occurring due to plastic deformation in vitroceramic masses in the tridymite primary crystallization compartment have medium values. The first deformation effect which appears at temperature $T_2 = 640°$, corresponding to the nucleation of fluoride crystals, presents a smaller value $\frac{\Delta L_1}{L} \simeq -1.8‰$, while the second effect which no longer appears at the temperature $T_4 = 835°$, corresponding to silicate nucleation, presents an almost double value $\frac{\Delta L_2}{L} \simeq -3.2‰$.

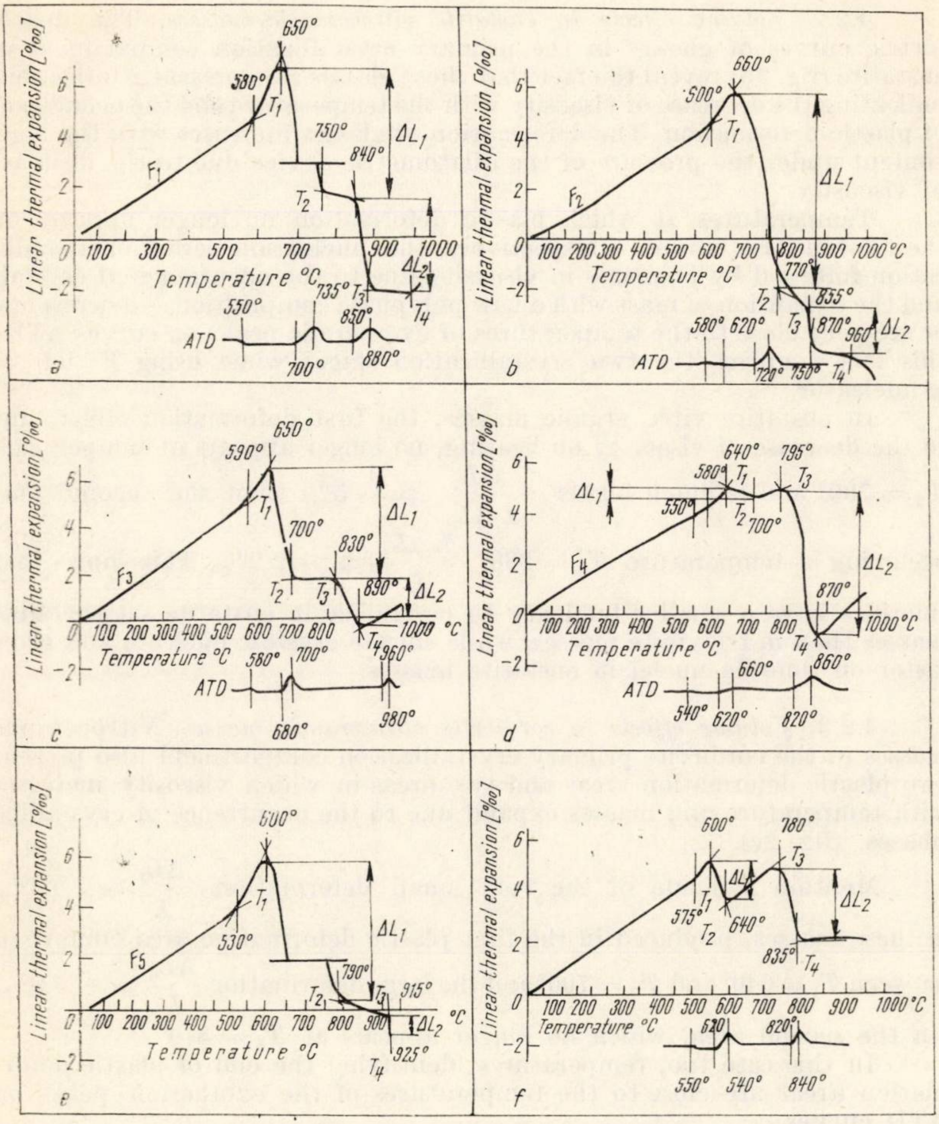

Fig. 2. — Volume effects involved in heat expansion and ATD characteristic to F$^-$ nucleated vitroceramic masses of the $Na_2O-MgO-Al_2O_3-SiO_2$-system.

a – tridymite, *b* – enstatite, *c* – cordierite, *d* – forsterite, *e* – spinel, *f* – sapphirine vitroceramics.

This shows that fluorides nucleate at higher viscosities than do silicates in tridymite vitroceramic masses.

4.2.2. *Volume effects in enstatite vitroceramic masses.* The dilatometric curves of glasses in the primary crystallization compartment of enstatite (fig. 2b) reveal the fact that these glasses also present 2 inflections indicating the decrease of viscosity with the temperature and the occurrence of plastic deformation. The deformation of glasses increases with the MgO content under the pressure of the dilatometric device due to the decrease of viscosity.

Temperatures at which plastic deformation no longer appears on the dilatometric curves — respectively the nucleation period of crystallization followed by increases in viscosity due to the occurrence of crystals and the expansion of mass with a new polyphase composition — correspond or are very close to the temperatures of exothermic peaks on curves ATD ; this fact confirms the two crystallization stages when using F^- ion as a nucleator.

In enstatite vitroceramic masses, the first deformation effect, due to the decrease of viscosity on heating, no longer appears at temperature $T_2 = 700°$ and is much higher $\frac{\Delta L_1}{L\Delta L_2} \simeq -5\%$ than the second one, occurring at temperature $T_4 = 890°$ $\frac{L\Delta L_2}{L} \simeq -2.2^0/_{00}$. This shows that fluorides have a smaller tendency to crystallize in enstatite vitroceramic masses than in tridymite masses, while silicate crystals nucleate and grow faster on fluoride nuclei in enstatite masses.

4.2.3. *Volume effects in cordierite vitroceramic masses.* Vitroceramic masses in the cordierite primary crystallization compartment also present two plastic deformation areas and two areas in which viscosity increases with temperature and masses expand due to the occurrence of crystalline phases. (fig. 2c).

Mention is made of the very small deformation $\frac{\Delta L_1}{L} \simeq -0.4^0/_{00}$ in these masses, produced in the first plastic deformation area comprised between $T_1 = 640°$ and $T_2 = 700°$ and the large deformation $\frac{\Delta L_2}{L} \simeq -5.8^0/_{00}$ in the second area, which no longer appears at $T_4 = 870°$.

In this case too, temperatures identifying the end of plastic deformation areas are close to the temperatures of the exothermic peaks on ATD curves.

A characteristic phenomenon for these masses is the fact that fluoride nucleation occurs during the heating process involving the lowest reduction of viscosity.

4.2.4. *Volume effects in forsterite, spinel and sapphirine vitroceramic masses.* The volume effects revealed by the dilatometric curve of those glasses (fig. 2d, f, g) are generally similar to those glasses investigated in the other primary crystallization compartments. Each of them presents two plastic deformation areas which end at temperatures close to the exothermic peaks on ATD curves.

A particularity of glasses with composition situated in these primary crystallization compartments and characterized by a lower-than 50% SiO_2 content, is the very large deformation in the first dilatometric plastic deformation area (forsterite $\frac{\Delta L_1}{L} \simeq -2\%$ and sapphirine $\frac{\Delta L_1}{L} \simeq -5\%$) which indicates the lowest viscosity at which nucleation of fluoride crystals occurs.

Viscosity increases at temperatures beyond those involved in the nucleation of crystallization due to the occurrence of crystalline phases and masses with a new phase composition present an almost constant expansion or a slight contraction due to crystallization.

4.3. ACTION OF F^- IONS ON THE STRUCTURE AND VOLUME EFFECTS IN VITROCERAMIC MASSES

Table 1 presents the average expansion coefficients α_{20}^{300} of vitro ceramic masses treated at 850° and 950° for 60 minutes and at 1000° under the heating conditions which correspond to the determination of the dilatometric curve. The values of the expansion coefficients of vitroceramic masses subjected to heat treatment at various temperatures are not specific for the compounds corresponding to the primary crystallization compartments in which they are situated.

Table 1

Volume effects and heat expansion of fluorine-nucleated ceramic masses of the $Na_2O-MgO-Al_2O_3-SiO_2$-system

Vitroceramic masses	Plastic deformation		$\alpha_{20}^{300} \times 10^{-6}$			
	$\frac{\Delta L_1}{L} \cdot 10^3$	$\frac{\Delta L_2}{L} \cdot 10^3$	Glass	Vitroceramics subjected to heat treatment at temperatures of :		
				850°	950°	1000°
Tridymite	− 1.8	−3.2	8.5	11.5	12.00	12.5
Enstatite	− 5.0	−2.2	8.6	12.1	13.5	13.5
Cordierite	− 0.4	−5.0	7.5	10.4	11.5	11.6
Forsterite	−20	−2.0	8.1	13.5	14.6	14.7
Spinel	− 7.5	−2.0	7.7	15.2	15.3	15.3
Sapphirine	−50	−0.8	8.0	—	—	12.3

Within this system, cordierite glasses as well as cordierite vitroceramic masses present the least volume effects due to heat expansion. This shows that the incipient cordierite vitreous microphases have a remarcable heat stability, similar to the cordierite crystalline phases. The volume behaviour to temperature is different in the various vitroceramic masses of this system which, from point of view of dilatometry, follow the criterion of the primary crystallization compartments of crystalline phases. This shows that the structuration of vitreous microphases is oriented and is according with the relations of crystalline phase heat equilibrium of the system and varies in relation to the primary phase crystallization compartment including the mass composition; it divides vitroceramic masses into : tridymite, cordierite forsterite, spinel and sapphirine.

The small differences among the expansion coefficients of the vitroceramic masses in various primary crystallization compartments are due to the small proportion of the crystalline phases specific to each compartment compared to the preponderating crystalline phase which is represented by one single type of fluorosilicate belonging to the mica family (phlogopite).

5. CONCLUSIONS

1. The similarity between temperatures causing crystallization nucleation and viscosity increases with the increase of temperature and the temperatures of the exothermic peaks on the ATD curve confirm the two crystallization stages of fluorine-nucleated vitroceramic masses of the $Na_2O-MgO-Al_2O_3-SiO_2$-system. The first stage, according to X-ray diffraction, corresponds to fluoride crystallization and the second, to fluorosilicates.

2. Viscosity at which fluorine nucleation occurs in masses of the $Na_2O-MgO-Al_2O_3-SiO_2$-system decreases with the increase in the MgO content.

3. Cordierite vitrocearmic masses present the highest viscosity at which nucleation of fluoride crystals occurs.

4. The volume behaviour involved in heat expansion of vitroceramic masses having compositions situated in various primary crystallization compartments shows that the structuration of vitreous microphases is based on the relations of phase heat equilibrium of the system and divides vitroceramic masses into : tridymite, enstatite, cordierite, forsterite, spinel and sapphirine.

5. Crystallization as a preponderant phase of a single type of fluorosilicate belonging to the mica family (phlogopite), in all fluorine-nucleated vitroceramic masses of the primary crystallization compartment of the $Na_2O-MgO-Al_2O_3-SiO_2$-system, subjected to heat treatment between 850–1000°, indicates the selectivity impressed by F^- ions as nucleators on the crystallization of these masses.

Revue Roumaine de Chimie, **18**, *1*, 11–22 (1973)

THERMODYNAMIC PROPERTIES OF THE RECIPROCAL MIXTURES OF FUSED SALTS : AgCl+(K, Rb, Cs)I

S. STERNBERG and LUCIA BEJAN

Institute of Physical Chemistry, Str. Galați 31, Bucharest, Romania

Received May 16, 1972

The partial molar thermodynamic properties of AgI in reciprocal mixtures of fused salts AgCl + KI, AgCl + RbI and AgCl + CsI have been calculated from e.m.f. measurements of the formation galvanic cells. The thermodynamic functions ; $\Delta\mu_{AgI}$, ΔS_{AgI} and ΔH^{M}_{AgI} from the experimental data are compared with those calculated from the enthalpies of the exchange reactions AgI + MeCl = = AgCl + MeI where Me = K, Rb, Cs, taking into account the polarization energy of the anion by the two cations.

1. – INTRODUCTION

In previous papers [1–3] a thermodynamic study of reciprocal systems of fused salts AgI + KCl, AgI + KBr, AgI + RbCl and AgI + CsCl was presented.

In this paper we present the thermodynamic study of reciprocal mixtures of AgCl + KI, AgCl + RbI and AgCl + CsI based on e.m.f. measurements of the formation cells :

$$Ag(s)\ \|AgCl(l,\ x_1) + KI(l,\ x_2)\|\ I_2(g,\ 1\ atm)\ \text{graphite}$$

$$Ag(s)\ \|AgCl(l,\ x_1) + RbI(l,\ x_2)\|\ I_2(g,\ 1\ atm)\ \text{graphite}$$

and

$$Ag(s)\ \|AgCl(l,\ x_1) + CsI(l,\ x_2)\|\ I_2(g,\ 1\ atm)\ \text{graphite}$$

For the study of these systems we used formation cells with iodine electrode, because the equilibrium :

$$MeX + 1/2\ I_2 \rightleftarrows MeI + 1/2\ X_2$$

is practically completely shifted to the left.

[1] S. STERNBERG and L. BEJAN, *Rev. Roumaine Chim.*, **14**, 303 (1969).

[2] S. STERNBERG and L. BEJAN, *J. Chem. Thermodynamics*, **2**, 341 (1970).

[3] S. STERNBERG and L. BEJAN, *Rev. Roumaine Chim.*, **16**, 175 (1971).

Details of the cell and the characteristics of the reversible iodine electrode have been given in previous works.[1,4,5] The e.m.f.'s were measured using a "Solartron" type L.M. 1440.2 digital voltmeter. E.m.f.'s measurements were effected for different molar fractions at different temperatures. The reproducibility of the experimental values was of 1-2 mV.

Pure chemical salts were used. AgCl, KI, RbI and CsI were first melted and purified by bubbling with gaseous halogenated acids.

2. – RESULTS AND DISCUSSION

In reciprocal mixtures one must consider a chemical reaction, e.g. in the present case :

$$\mathrm{AgI}(l) + \mathrm{MeCl}(l) \rightleftarrows \mathrm{AgCl}(l) + \mathrm{MeI}(l)$$

where Me = K, Rb, Cs. The phase diagrams[6] of these systems indicate that the mixtures AgI + MeCl are stable pairs while the mixtures AgCl + MeI are unstable pairs, being transformed into the corresponding stable pairs.

In previous works the mixtures situated on the left side of the equilibrium were studied, while in this paper the right side systems, namely the unstable pairs will be dealt with.

The e.m.f.'s *vs.* temperature for different molar fractions of the mixtures AgCl + (K, Rb, Cs)I are listed in tables 1–3. The functions $E = f(T)$ were obtained from about 20–30 points by the least squares method calculated with a computer. Since the unstable pairs of salts in the melt are transformed into stable pairs giving rise to AgI, the thermodynamic functions of AgI in the corresponding mixtures have been computed.

The partial molar chemical potential of silver iodide in the mixture, $\Delta\mu_{\mathrm{AgI}}$ – namely the difference between the chemical potential μ_1 of AgI in the mixture with the molar fraction $x_1 = x_{\mathrm{AgCl}}$ and the chemical potential μ^0 of pure AgI – was computed from e.m.f.'s measurements :

$$\Delta\mu_{\mathrm{AgI}} = \mu_1 - \mu^0 = -\mathcal{F}[E(x_1) - E^0] \qquad (1)$$

where E^0 refers to cells with pure AgI while $E(x_1)$ refers to cells with mixture.

The partial molar entropy was calculated from thermal coefficients :

$$\Delta S_{\mathrm{AgI}} = S_1 - S^0 = -\mathrm{d}(\mu_1 - \mu^0)/\mathrm{d}T = \mathcal{F}\left[\frac{\mathrm{d}E(x_1)}{\mathrm{d}T} - \frac{\mathrm{d}E^0}{\mathrm{d}T}\right] \qquad (2)$$

while the partial molar heat of mixing of AgI was computed using the relation :

$$\Delta H_{\mathrm{AgI}} = H_1 - H^0 = \mu_1 - \mu^0 + T(S_1 - S^0) \tag{3}$$

Tables 1—3 contain also the values of the partial molar thermodynamic functions of AgI, both those resulting from experimental data and those computed Flood, Førland and Grjotheim theory,[7] taking into account the deviations from the random distribution.

According to Temkin[8] the partial molar entropy of silver iodide in AgCl + MeI mixtures, where Me = K, Rb, Cs is given by the relation :

$$S_1 - S^0 = - R\{\ln x(\mathrm{Ag}^+)x(\mathrm{I}^-)\} = - R \ln x_1x_2 \tag{4}$$

Førland[9] suggests a corrected relation for the configurational entropy in the expression of which one takes into account the deviations from the random distribution (the quasichemical theory) :

$$S_1 - S^0 = - R \ln x_1x_2 - 1/2x_1x_2\,[x_1 + x_2 - 3x_1x_2]\,\frac{(\Delta H')^2}{zRT^2} \tag{5}$$

According to Flood, Førland and Grjotheim[7] the first term of the partial molar heat of mixing due to the interaction between the nearest neighbours (cation-anion), is :

$$\Delta H_{\mathrm{AgI}} = H_1 - H^0 = x_1x_2\,\Delta H \tag{6}$$

where ΔH refers to the above ionic exchange reaction.

Førland[9] considers also the existence of certain variations of the energies of ionic interactions between the following nearest neighbours (cation-cation and anion-anion interactions), similar to those occurring in binary mixtures of fused salts :

$$\Delta H^{\mathrm{M}}_{\mathrm{AgI}} = H_1 - H^0 = x_1x_2\,\Delta H + x_2^2(x_1b_{\mathrm{Cl}} + x_2b_{\mathrm{I}}) + x_1^2(x_2b_{\mathrm{Me}} + x_1b_{\mathrm{Ag}}) +$$
$$+ x_2x_1\,[x_2(b_{\mathrm{Ag}} - b_{\mathrm{Me}}) + x_1(b_{\mathrm{I}} - b_{\mathrm{Cl}})] \tag{7}$$

where the b parameters are the interaction parameters in equations of the type $H_1^{\mathrm{E}} = bx_2^2$, of the four binary mixtures which can form a reciprocal system. The index letters refer to the common ion of the binary mixture.

[9] T. Førland in "Fused Salts" Editor B. R. Sundheim, McGraw-Hill Book Company, New York, 1964, p. 63—164.

If one considers also the deviations from the random distribution one obtains the relation :

$$\Delta H^{M}_{AgI} = H_1 - H^0 = \Delta H_{AgI}(\text{eqn. } 7) - x_1x_2(x_1 + x_2 - 3x_1x_2)\frac{(\Delta H')^2}{zRT} \quad (8)$$

The partial molar chemical potential of AgI is computed from the equations :

$$\Delta\mu_{AgI} = \Delta H_{AgI}(\text{eqn. } 6) - T\,\Delta S_{AgI}(\text{eqn. } 4) \quad (9)$$

$$\Delta\mu_{AgI} = \Delta H_{AgI}(\text{eqn. } 7) - T\,\Delta S_{AgI}(\text{eqn. } 4) \quad (10)$$

$$\Delta\mu_{AgI} = \Delta H_{AgI}(\text{eqn. } 8) - T\,\Delta S_{AgI}(\text{eqn. } 6) \quad (11)$$

The relations (6—11) have been applied to the computation of the partial molar thermodynamic functions of AgI in the systems AgCl + + (K, Rb, Cs)I, where x_1 refers to the weighed molar fraction of AgCl and x_2 to that of alkali iodide (K, Rb, Cs)I.

Førland and co-workers[10] have applied this theory to the AgBr + + NaCl system, taking for $\Delta H'$ a value selected so that a good agreement with the experimental values of entropy has been observed.

We applied the theory of Flood, Førland and Grjotheim to the systems previously studied,[1-3] but some changes in the method of computation of $\Delta H'$ have been effected; namely we consider the following value resulting from relation[2]:

$$\Delta H' = \Delta H + \frac{\Sigma b_i}{2} \quad (12)$$

where ΔH was selected so as to supply a value in good agreement with the experimental values of the corresponding partial molar functions. In the case of AgCl + (K, Rb, Cs)I systems the values which were selected for $\Delta H'$, were those used for the stable salt pairs.

Table 4 contains the heats of reaction (ΔH) for stable pairs previously studied as well as $\frac{\Sigma b_i}{2}$ terms taken from the literature[5,11-14] and the values of $\Delta H'$ resulting from equation (12).

AgI+RbCl	+7936	+8600	−3603	+4997
AgI+CsCl	+7670	+8500	−5250	+3250

Tables 1–3 give also the thermodynamic activities of AgI in the corresponding mixtures computed by the Temkin relation,

$$a_{\mathrm{AgI}} = x_{\mathrm{Ag^+}} \cdot x_{\mathrm{I^-}} = x_1 x_2 \tag{13}$$

as well as the values of thermodynamic functions of AgI resulting both from experimental data and computed from the relations (6), (8), (11). Experimental and computed results are in satisfactory agreement.

The partial molar chemical potentials of AgI in the three mixtures AgCl + KI, AgCl + RbI and AgCl + CsI are plotted in figures 1–3. The theoretical curves are computed using relations (9)–(11) and the points represent the experimental data. It may be seen that all the curves present a maximum. The theoretical curves computed from equation (9) present the maximum at $x_1 = 0.5$, while both theoretical curves computed from relations (10) and (11) in which the interaction parameters are considered, have the maxima shifted to molar fractions x_1 higher than 0.5. For the AgCl + KI system the maximum is shifted to $x_1 = 0.55$, for the AgCl + + RbI at $x_1 = 0.6$, while for the AgCl + CsI system the maximum is located at $x_1 = 0.63-0.65$.

Figures 1–3 show that the experimental maxima are also shifted with respect to $x_1 = 0.5$, the order of sequence being the same as for the theoretical maxima. The correction for the ordering process has a small value in all cases. The AgCl + RbI and AgCl + CsI systems show a higher deviation of the experimental points corresponding to extreme values of molar fractions when the concentration of AgI in the mixture is small. Deviations have been observed also for the stable systems [1-3] with low concentration of AgI. In the case of dilute reciprocal solutions the theory of Flood and Førland might probably require some corrections.

The shape of the $\Delta\mu_{\mathrm{AgI}} - x_1$ curves can be explained as follows: since the ordering effect has a small value and, hence may be neglected, the chemical potential $\Delta\mu_{\mathrm{AgI}}$ can be calculated using the relation:

$$\Delta\mu_{\mathrm{AgI}} = \Delta H x_1 x_2 + f(b_i) + RT \ln x_1 x_2 \tag{14}$$

The term $\Delta H x_1 x_2$ is positive and represents the component of the heat of mixing which results from the heat of the exchange reaction. The term $f(b_i)$ represents the component of the heat of mixing resulting

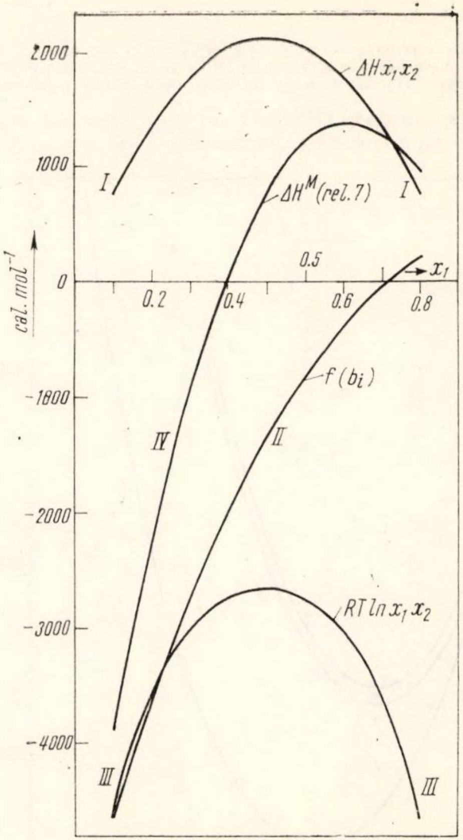

Fig. 4. — Components of the partial molar chemical potential for AgI

I, $\Delta H x_1 x_2$; II, $f(b_i)$; III, $R \ln x_1 x_2$; IV, ΔH^M (eq. 7).

from the contributions of polarization and London energies. The value of $f(b_i)$ results from equation (7). The term $RT \ln x_1x_2 = - T\Delta S$ results from the mixing entropy of a system with four different ions and is always negative.

In figure 4 all the three terms are plotted. The first and the third terms have a maximum for the fraction $x_1 = 0.5$ (curves I and III). This maximum results from the product $x_1x_2 = a_{\mathrm{AgI}}$ which represents the thermodynamic activity of silver iodide computed after Temkin :

$$a_{\mathrm{AgI}} = x_{\mathrm{Ag}^+} . x_{\mathrm{I}^-}$$

This behaviour results actually from the reciprocal system,character of the melt studied. From the combination of these two terms (curves I and III fig. 4) one obtains $\Delta\mu_{\mathrm{AgI}}$ given by relation (9), and having a maximum for $x_{\mathrm{AgCl}} = 0.5$ (e.g. curve 1 from fig. 3).

The second term, $f(b_i)$, is always negative in the case of the systems studied by us, because their polarization energies are higher than London's [13,14,1-3] ones. It should be mentioned that these energies are not characteristic of the reciprocal mixtures. As in the case of binary mixtures the values of these energies depend firstly on the ratio $\mathrm{Ag}^+/\mathrm{Me}^+$. A curve without a maximum is obtained, since in this case the product x_1x_2 does not occur in the corresponding equation. Curve IV which results from the combination of curves I and II has the maximum shifted to $x_1 = 0.7$, while from curves III and IV the chemical potential $\Delta\mu_{\mathrm{AgI}}$ results which is represented by a curve having the maximum shifted to $x_1 \simeq 0.7$ (e.g. curve 2 of fig. 3).

Thus it has been proved that the shift of the maximum is due in fact to the exothermal polarization energy. The shift increases from K to Cs in the same order as the polarization energy for the binary mixtures with a common anion.

Figure 5 gives the experimental partial molar chemical potentials of AgI in the three mixtures. In all cases $\Delta\mu_{\mathrm{AgI}}$ are negative. The partial molar chemical potential of AgI increases in absolute value in the order :

$$\mathrm{AgCl} + \mathrm{CsI} < \mathrm{AgCl} + \mathrm{RbI} < \mathrm{AgCl} + \mathrm{KI}$$

just as in the case of the stable pairs AgI + MeX.[1-3] Table 4 shows that the less positive is the heat term $\Delta H'$, the more negative is $\Delta\mu_{\mathrm{AgI}}$.

For all the three systems studied, the heats of the exchange have very closely approaching values (experimental values of ΔH, table 4). The difference found for the expression of $\Delta\mu_{\mathrm{AgI}}$ arises from the term $\Sigma b_i/2$ and ultimately from the polarization energies which increase in absolute value in the following order :

$$|b_{\mathrm{Ag-K}}| < |b_{\mathrm{Ag-Rb}}| < |b_{\mathrm{Ag-Cs}}|$$

Thus it has been proved that in the case of the unstable as well as stable systems[1-3] it is absolutely necessary to take into account the correction term $f(b_i)$ in order to make an exact estimation of the mixing thermodynamic properties.

Figure 6 gives the plots of the partial molar entropies of mixing of AgI in the mixture AgCl + RbI. The third curve represents the graphically averaged values of ΔS^M_{AgI} determined experimentally.

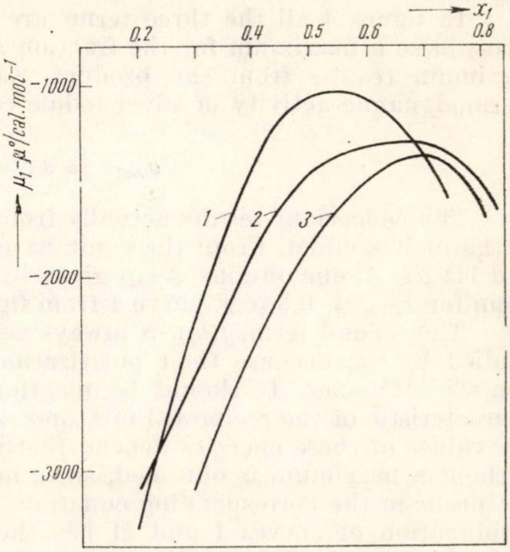

Fig. 5. — Experimental partial molar chemical potentials $\Delta\mu_{AgI}$ for AgI plotted against the mole fraction $x_1 = x_{AgCc}$ in mixtures :

1, (AgCl + KI) ; 2, (AgCl + RbI) ; 3, (AgCl + + CsI).

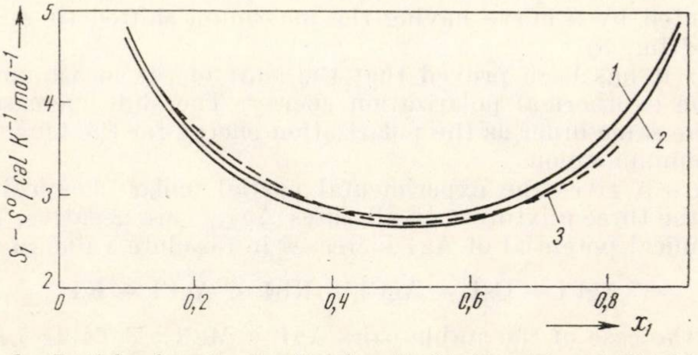

Fig. 6. — Partial molar entropies of mixing of AgI in the mixture AgCl + RbI.

1, Theoretical curve calculated according to equation (4) ; 2, theoretical curve calculated according to equation (5) ; Curve 3 represents the graphically averaged values of ΔS^M_{AgI} determined experimentally.

As may be seen from the figure 6 the ordering correction of the mixing entropy is very small and the experimental values occur between the two theoretical curves. A similar behaviour with respect to the mixing entropy is observed also in the other two systems.

LES ÉQUILIBRES DE PHASE DU SYSTÈME $Na_2O-CaO-Al_2O_3-SiO_2$.

ÉQUILIBRES DE PHASE DANS LE SOUS-SYSTÈME $Na_2O.Al_2O_3.6SiO_2-CaO.Al_2O_3.2SiO_2-3Al_2O_3.2SiO_2-Al_2O_3$ * INRÉRESSANT LA CÉRAMIQUE SUPERALUMINEUSE

R. DINESCU et M. CERCHEZ

Centre de Chimie Physique, 23 str. Dumbrava Roşie, Bucarest

Reçu le 10 juillet 1972

On a déterminé les relations de paragenèse quaternaire d'équilibre dans la zone alumineuse du système $Na_2O-CaO-Al_2O_3-SiO_2$, en délimitant le sous-système V $Na_2O.\ Al_2O_3.\ 6SiO_2-CaO.\ Al_2O_3.\ 2SiO_2-3Al_2O_3.\ 2SiO_2-Al_2O_3$; on a établi la surface quaternaire divariante $3Al_2O_3.\ 2SiO_2-Al_2O_3$. Dans le sous-système V sont déterminées des relations quantitatives qui permettent d'obtenir les phases coexistantes au traitement termique jusqu'à 1600° et on a élaboré un système modulaire de corrélation des conditions de paragenèse avec les propriétés des masses alumineuses du système.

1. INTRODUCTION

Dans des travaux antérieurs [1,2] on a déterminé les équilibres de phase dans la zone acide et alumineuse du sous-système $NAS_6-CAS_2-A_3S_2$-S.**)

La classification modulaire proposée [1] délimite les domaines de composition qui correspondent aux masses réfractaires de silice,semi-acides, silico-argileuses et alumino-argileuses, ainsi qu'aux masses de céramique fine alumino-siliceuses usuelles.

Le présent travail développe l'étude des équilibres de phase dans le sous-système adjacent : $NAS_6-CAS_2-A_3S_2-A$, noté avec le numéro V (fig. 1), sous-système qui intéresse les réfractaires et les porcelaines superalumineuses. Ce sous-système doit être examiné conjointement avec le sous-système I, $NAS_6-CAS_2-A_3S_2-S$, étant donné que l'incongruence dans le système quaternaire de la mullite déplace la courbe limite quaternaire G_7G_8 afférente au sous-système V, dans ce même système [2].

*) Dans ce travail on désigne par Al_2O_3 la phase de haute température: αAl_2O_3 (corindon).
**) N–Na_2O, C–CaO, A–Al_2O_3, S–SiO_2.

2. ÉQUILIBRES THERMIQUES DE PHASE DES MASSES QUATERNAIRES QUI CRISTALLISENT PRIMAIREMENT LA MULLITE ET LE CORINDON

Dans la figure 2 on présente la surface quaternaire divariante $e_{12}-G_7-G_8$, qui sépare les compartiments de cristallisation primaire de la mullite et du corindon.

Sur la surface quaternaire divariante $e_{12}-l-G_7-G_8-m$ (figure 2) s'établit l'équilibre thermique suivant :

$$A + A_3S_2 \rightleftarrows \text{liq } e_{12}lG_7G_8m \qquad (1)$$

On observe que l'intersection — suivant la courbe lm — du pseudo-système ternaire $NAS_6-CAS_2-A_3S_2$ avec la surface divariante $e_{12}-G_7-G_8$

montre l'extension des volumes de cristallisation primaire de la mullite et du corindon dans le sous-système NAS$_6$—CAS$_2$—A$_3$S$_2$—S, ainsi que dans le sous-système NAS$_6$—CAS$_2$—A_3S_2—S.

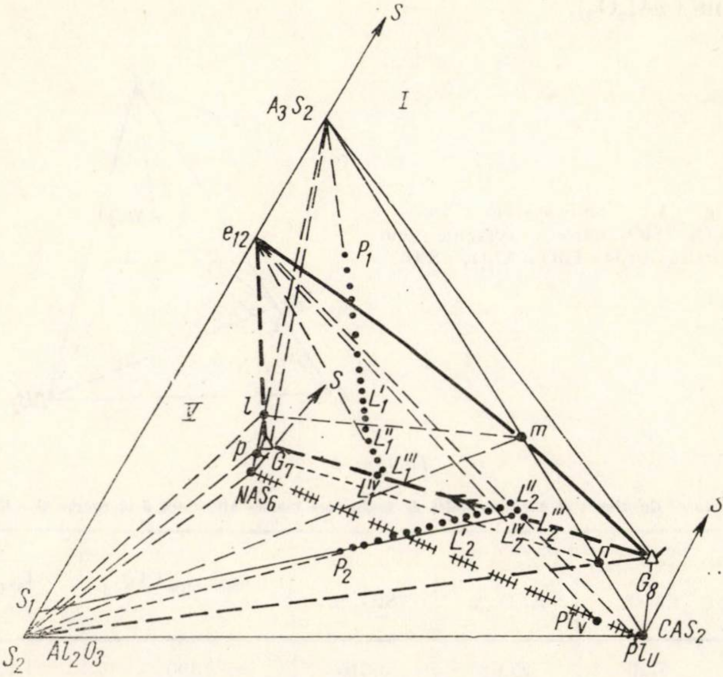

Fig. 2. — Équilibres de phase dans le sous-système NAS$_6$—CAS$_2$—A_3S_2—A et partiellement dans le sous-système NAS$_6$—CAS$_2$—A_3—S_2—S.

2.1. MASSES SITUÉES DANS LE SOUS-SYSTÈME V NAS$_6$—CAS$_2$—A_3S_2—A

On observe que, dans le volume contenant les masses à alumine en excès par rapport à celle des points de la surface A_3S_2—G_7—G_8 (figure 2), on trouve deux volumes de cristallisation primaire afférentes au sous-système V : celui de la mullite A_3S_2—m—l—e_{12}, celui du corindon A—e$_{12}$—l—p—n—m.

a) Les masses situées dans le volume A_3S_2—m—l—e_{12} cristallisent primairement la mullite et la phase liquide finale se situe sur la courbe univariante quaternaire G_7—G_8 (figure 2, masse P$_1$).

b) Les masses situées dans le volume A—e_{12}—l—p—n—m cristallisent primairement le corindon et présentent une phase liquide finale située également sur la courbe limite G_7—G_8 (figure 2, masses P_2).

Dans le tableau 3 on indique les équations des volumes de cristallisation primaire de la mullite et du corindon dans le sous-système NAS$_6$—CAS$_2$—A_3S_2—A.

Tableau 3

Équations des volumes de cristallisation de la mullite ($A_3S_2-m-l-e_{12}$) et du corindon ($A-e_{12}-l-p-n-m$) dans le sous-système $NAS_6-CAS_2-A_3S_2-A$ et des volumes de cristallization de la mullite ($A_3S_2-m-G_8-G_7-l$) et du corindon ($l-m-n-p-G_7-G_8$) dans le sous-système $NAS_6-CAS_2-A_3S_2-S$

Volume	Plan limite	Équation de plan limite	Équation du volume
	a) Sous système	$NAS_6-CAS_2-A_3S_2-A$	
$A_3S_2-m-l-e_{12}$ (phase primaire mullite)	$A_3S_2-l-e_{12}$ $A_3S_2-m-e_{12}$ A_3S_2-m-1	$P_1=S+A+N-100=0$ $P_2=N=S+A+C-100=0$ $P_3=S+0{,}42A-1{,}59N-58{,}34=0$	$P_1<0$; $P_2<0$; $P_3>0$

2.2. MASSES SITUÉES DANS LE SOUS-SYSTÈME $NAS_6-CAS_2-A_3S_2-S$

a) Eu égard à l'incongruence de la mullite dans les systèmes ternaires et quaternaires, les masses situées dans le volume $l-m-n-p-G_7-G_8$, qui font partie du sous-système $NAS_6-CAS_2-A_3S_2-S$, cristallisent primairement le corindon ; la mullite apparaît comme phase secondaire par la dissolution de l'alumine, quand la composition de la phase liquide se situe sur la courbe G_7-G_8. Le liquide final possède la composition située sur la courbe univariante E_2-E_4 (le trajet de fusion parcourt également la surface $E_2E_4G_7G_3$ dans le sous-système $NAS_6-CAS_2-A_3S_2-S$ *).

Dans les figures 2 et 3 sont représentées conjointement avec le sous-système $NAS_6-CAS_2-A_3S_2-A$, les fractions des volumes qui font partie du sous-système $NAS_6-CAS_2-A_3S_2-S$.

Le trajet de fusion d'une masse P_3 située dans le volume $l-m-p-n-G_7-G_8$ est indiqué dans la figure 3.

---

* Voir les travaux antérieurs. [1, 2]

b) Dans le même sous-système se trouvent également placées les masses du volume $A_3S_2—l—G_7—G_3—m$ (figure 3) qui cristallisent primairement la mullite et qui terminent la solidification toujours avec un liquide sur la courbe $E_2—E_4$. Dans le tableau 3 sont aussi indiquées les équations

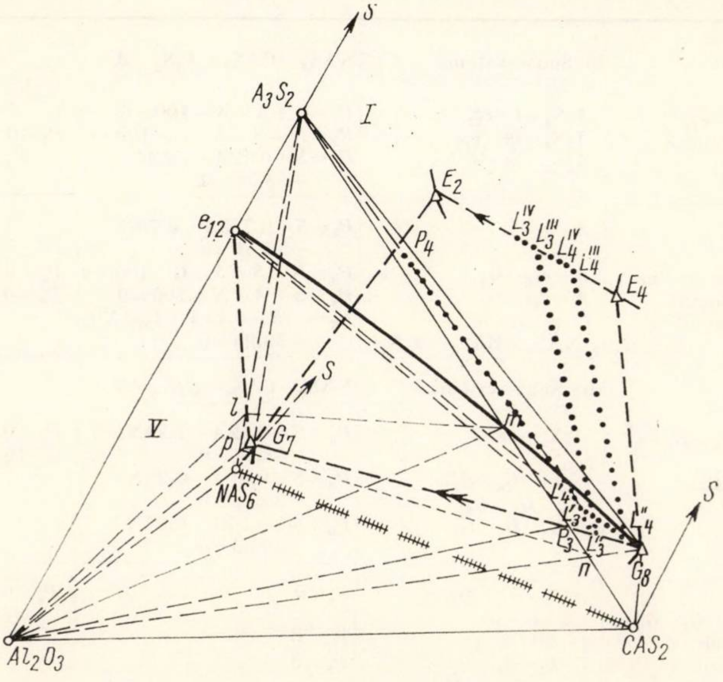

Fig. 3. — Le compartiment de cristallisation primaire de la mullite et les phases de cristallisation de la masse fondue P dans le sous-système $NAS_6—CAS_2— A_3S_2—S$ (les volumes $l—m—p—n—G_7—G_8$ et $A_3S_2—m—G_7—G_8—l$).

$$t_{P_3} \cdots t_{L_3^{I}} \quad A \rightleftarrows \text{liq } P_3 \ldots L_3^{I}$$

$$t_{L_3^{I}} \cdots\cdot t_{L_3^{II}} \quad A + A_3S_2 \rightleftarrows \text{liq } L_3^{I} \ldots L_3^{II}$$

$$t_{L_3^{II}} \cdots t_{L_3^{III}} \quad A_3S_2 + \text{ss}Pl_3^{II} \ldots \text{ss}Pl_3^{III} \rightleftarrows \text{liq } L_3^{II} \ldots L_3^{III}$$

$$t_{L_3^{III}} \cdots t_{L_3^{IV}} \quad S + A_3S_2 + \text{ss}Pl_3^{III} \ldots \text{ss}Pl_4^{IV} \rightleftarrows \text{liq } L_3^{III} \ldots L_3^{IV}$$

$$t_{L_3^{IV}} \quad S + A_3S_2 + \text{ss}Pl_3^{IV} \rightleftarrows \text{liq } L_3^{IV}$$

de définition des surfaces qui delimitent ce volume. On observe que le volume $A_3S_2—l—G_7—G_8—m$ est très étroit, se trouvant pratiquement dans la limite des erreurs de lecture sur le diagramme.

Sur la figure 3 on présente le trajet de cristallisation d'une masse P_4 de ce volume.

En même temps que la délimitation de la surface quaternaire divariante $A_3S_2—A$ et en considérant les déterminations présentées dans les travaux antérieurs [1,2], on a complètement défini le compartiment de cristallisation primaire de la mullite.

3. RELATIONS QUANTITATIVES POUR LA DÉTERMINATION DES PHASES D'ÉQUILIBRE PENDANT LE TRAITEMENT THERMIQUE DES MASSES SUPERALUMINEUSES DANS LE SOUS-SYSTÈME $NAS_6-CAS_2-A_3S_2-A$

Le calcul de la proportion d'équilibre du corindon et de la masse fondue d'une part et du corindon de la mullite de la masse fondue d'autre part est illustré dans le volume $A-e_{12}-l-p-n$ et respectivement sur la surface quaternaire divariante, à des températures allant jusqu'à 1600° ; le calcul est réalisé par l'application des relations du centre de gravité suivant le mode de travail indiqué dans des travaux antérieurs [1,2], en assimilant les surfaces isothermes à des plans, la composition des phases étant déterminée analytiquement.

Les isoplèthes et les isothermes de la surface $e_{12}-l-m-G_7-G_8$ sont indiquées dans la figure 4 ; on observe sur cette figure la position rapprochée des isothermes, dans la zone de 20 à 35% Al_2O_3, ce qui montre la grande influence sur les propriétés réfractaires exercée par la teneur en Al_2O_3 sur ces masses. Dans le tableau 4 on indique les formules qui permettent de déterminer les composants de phase d'équilibre en fonction de la composition oxydique et de la température de cuisson, dans le volume de cristallisation primaire de l'alumine, dans le sous-système $NAS_6-CAS_2-A_3S_2-A$.

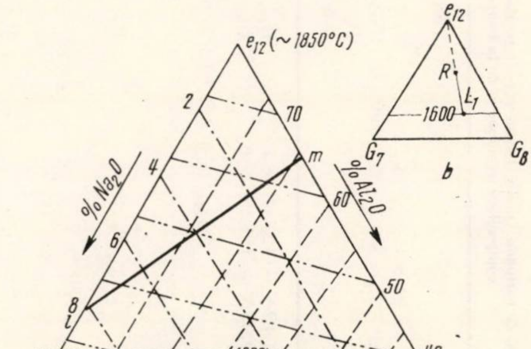

Fig. 4. — La surface quaternaire divariante $e_{12}-G_7-G_8$:

a) Isothermes et isoplètnes; b) Trajet de fusion et solidification

Le trajet typique de fusion est représenté sur la figure 2 (masse P_2).

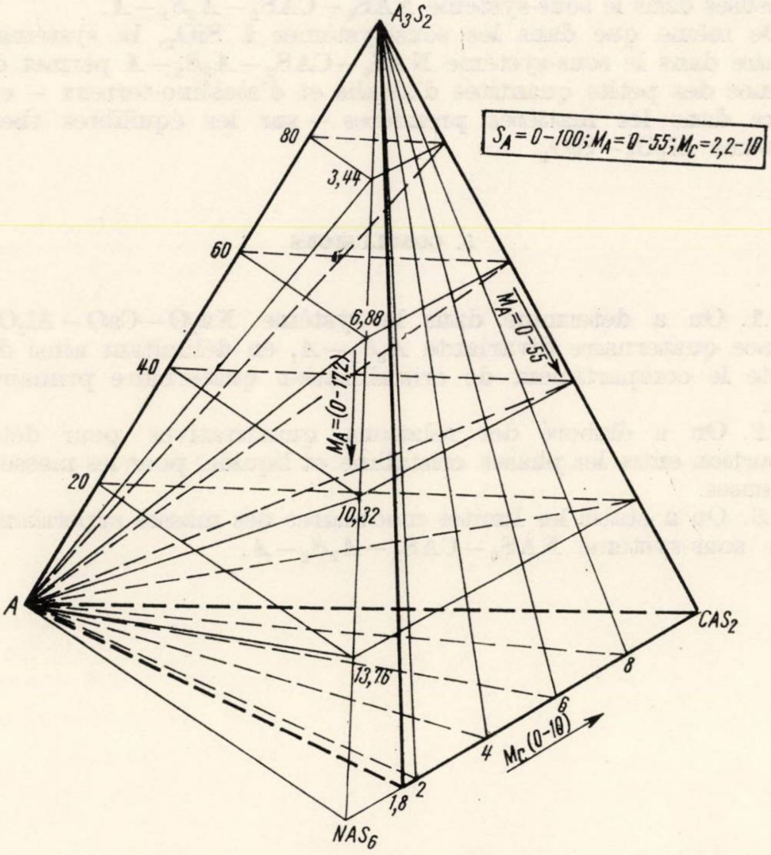
4. SYSTÈME MODULAIRE POUR LES MASSES CÉRAMIQUES SUPERALUMINEUSES

Le système modulaire proposé réalise la corrélation des propriétés des masses superalumineuses avec les conditions de paragenèse du sous-système $NAS_6 - CAS_2 - A_3S_2 - A$, suivant la méthode indiquée antérieurement.[1]

a) *Degré de saturation par rapport à l'alumine* (S_A). La saturation en alumine représente les quantités théoriques de Al_2O_3 en excès, en comparaison de la quantité d'Al_2O_3 liée chimiquement. En exprimant en équivalents molaires il résulte :

$$S_A = \%\,Al_2O_3 - (1{,}82\%\,CaO + 1{,}65\,Na_2O - 2{,}55\%\,SiO_2) \qquad (2)$$



A_3S_2
$S_A=0-100; M_A=0-55; M_C=2,2-10$

Fig. 5. — Position des masses superalumineuses dans le sous-système $NAS_6 - CAS_2 - A_3S_2 - A$.

Revue Roumaine de Chimie, 18, 1, 23–34 (1973)

Le lieu géométrique des masses ayant un degré égal de saturation représente des plans parallèles au plan $NAS_6-CAS_2-A_3S_2$.

b) *Le module S* est le rapport :

$$S = \frac{\%CaO + \%Na_2O}{\%SiO_2} 100 \qquad (3)$$

Le lieu géométrique des masses ayant le même S est représenté par des plans qui convergent des côtés $NAS_6-A_3S_2$ et $CAS_2-A_3S_2$, dans le sommêt Al_2O_3 du tétraèdre.

c) *Le module C* est formulé de la même façon que dans le cas des masses du sous-système à SiO_2 *, étant donné que le lieu géométrique des masses à C égal représente des plans qui convergent du côté NAS_6-CAS_2 sur l'arrête $Al_2O_3-SiO_2$ du tétraèdre.

On indique dans la figure 5 les limites modulaires des masses superalumineuses dans le sous-système $NAS_6-CAS_2-A_3S_2-A$.

De même que dans les sous-systèmes à SiO_2, la systématisation modulaire dans le sous-système $NAS_6-CAS_2-A_3S_2-A$ permet d'établir l'influence des petits quantités d'alcalis et d'alcalino-terreux — existants toujours dans les matières premières — sur les équilibres thermiques du système $Al_2O_3-SiO_2$.

5. CONCLUSIONS

5.1. On a déterminé dans le système $Na_2O-CaO-Al_2O_3-SiO_2$ la surface quaternaire divariante A_3S_2-A, en délimitant ainsi de façon complète le compartiment de cristallisation quaternaire primaire de la mullite.

5.2. On a élaboré des relations quantitatives pour déterminer la proportion entre les phases cristalline et liquide, pour les masses superalumineuses.

5.3. On a établi les limites modulaires des masses superalumineuses dans le sous-système $NAS_6-CAS_2-A_3S_2-A$.

RÉACTIONS D'ÉCHANGE ISOTOPIQUE ENTRE Tl(III)–COMPLEXÉ ET ^{204}Tl(I)

AL. CECAL et I. A. SCHNEIDER

Université « Al. I. Cuza », Faculté de Chimie, 11, str. 23 August, Jassy, Roumanie

Reçu le 7 juillet 1972

Le but de ce travail est de déterminer l'influence de quelques combinaisons complexes du Tl(III) et de la nature de la liaison métal-ligand sur les paramètres cinétiques et thermodynamiques caractéristiques de la réaction d'échange isotopique pour le système ^{204}Tl(I)–Tl(III). On y estime les valeurs du temps de semi-échange, des constantes de vitesse, des énergies et entropies d'activation et aussi du facteur préexponentiel.

INTRODUCTION

Il est bien connu que l'échange isotopique donne des indications précises sur la structure des combinaisons complexes et sur la nature de la liaison métal-ligand. Les auteurs du présent travail tâchent d'établri l'influence exercée par la structure et le type de liaison d'une combinaison complexe sur les paramètres qui caractérisent les réactions d'échange isotopique.

Dans ce but, on a préparé 14 composés complexes du Tl(III) avec un certain nombre de ligands organiques choisis de telle sorte qu'il existe entre eux et le métal central différentes sortes de liaison chimique. On a poursuivi ensuite chez les différentes combinaisons complexes, l'échange entre le ^{204}Tl(I) et le Tl(III) – complexé, la variation des paramètres cinétiques et thermodynamiques spécifiques de la réaction mentionnée

PARTIE EXPÉRIMENTALE

L'échange isotopique dans le système ^{204}Tl(I)–Tl(III)—complexé a été étudié par la synthèse des combinaisons complexes : Tl(III)-8-hydroxyquinoléine, Tl(III)-5, 7-dibromo-8-hydroxyquinoléine [1–2], Tl(III)-acide-8-hydroxyquinoléine-7-sulfonique, Tl(III)-acide-7-iodo-8-hydroxyquinoléine-5-sulfonique [3], $HTlBr_4$. pyridine, $HTlBr_4$. α-picoline, $HTlBr_4$. quinoléine, [4]

$HTlBr_4$. 2,6-lutidine, $HTlBr_4$. 2,4,6-collidine,[5] $HTlBr_4$. diantipyrylméthane,[6] Tl(III)-2, 2′-dipyridyl, Tl(III)-1, 10-phénanthroline,[7-9] Tl(III)-diéthyldithiocarbamate[10] et Tl(III)-thénoyltrifluoroacétone.[11] Les complexes obtenus à l'état solide ont été dissous dans de l'alcool éthylique, auquel on a ajouté de l'eau jusqu'à la proportion 75 alcool : 25 eau.

Le Tl(I) radioactif nous a été procuré par l'Institut de Physique Atomique sous forme de $^{204}TlNO_3$ solide. Celui-ci a été dissous dans de l'acide azotique (33%) et à la solution on a ajouté du $TlNO_3$ comme porteur. On a déterminé la concentration totale du Tl monovalent par voie gravimétrique.[12]

On a introduit des quantités différentes de réactants dans des flacons de 250 ml, en ajoutant une solution tampon $CH_3COOH-CH_3COONa$ (0,2 M) et une solution de KNO_3 pour régler le pH et la force ionique (à 0,5). Pour poursuivre la cinétique de la réaction d'échange, on a fait à des intervalles de temps, de chaque échantillon, une extraction de 2 ml solution. La séparation des deux états d'oxydation du thallium a été réalisée par la méthode de Harbottle et Dodson[13], en précipitant le Tl(I) sous forme de Tl_2CrO_4. On a lavé et filtré le précipité respectif en posant le volume de la solution à 40 ml. De cette solution on a pris une quote-part de 14 ml, dont on a mesuré l'activité avec un compteur d'immersion dans le liquide (VA–Z–410) lié à un compteur électronique de type VSP–1960. On a poursuivit les réactions d'échange jusqu'à l'équilibre, c'est-à-dire, jusqu'à ce que les dernières 2–4 lectures de l'activité eussent donné des valeurs approximativement constantes.

RÉSULTATS ET DISCUSSIONS

L'estimation des paramètres cinétiques : le temps de semi-échange (en heures) et la constante de vitesse (en l/mole.h) a été faite en partant de la relation de McKay[14-16]. Dans ce but, on a tracé des droites en coordonnées : $-\log(1 - F)$ en fonction du temps, de sorte, que pour la valeur $F = 1/2$ du facteur d'échange sur l'ordonnée, corresponde sur l'abscisse la valeur du temps de semi-échange ($t_{1/2}$). En déterminant ce paramètre, on a calculé la constante de vitesse :

$$k = \ln 2 / [t_{1/2}(a + b)]$$

Les résultats obtenus sont indiqués sur les tableaux 1–3.

L'influence du pH sur les paramètres cinétiques mène à la conclusion qu'il existe deux chemins différents et concurrents pour la réaction d'échange,[18] l'un indépendant de la concentration des ions d'hydrogène et l'autre dépendant de cette concentration.

Les données présentées plus haut laissent voir qu'il y a une différence prononcée entre les paramètres cinétiques et thermodynamiques caractéristiques des réactions d'échange isotopique soumises à notre examen, en fonction du type de combinaison complexe et de la nature de la liaison métal-ligand dans cette combinaison. On observe que les paramètres respectifs varient, dans le même groupe de combinaisons complexes, en fonction du substituent greffé au noyau de base, chose très importante pour la clarification de l'effet produit par les substituents sur la réactivité de la molécule organique respective.

Pour les combinaisons complexes du Tl(III), par exemple avec la 8-hydroxyquinoléine et ses dérivés, les substituents $R = Br$, SO_3H et I introduits dans la position 7 du noyau de la 8-hydroxyquinoléine influencent différemment la liaison $0-Tl$.[19-21]

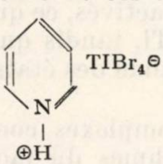
[20] C. K. Ingold, « Introduction to Structure of Organic Chemistry », G. Bell and Sons Ltd. Londres, 1960.

[21] E. H. Rodd, « Chemistry of Carbon Compounds », Elsevier, Amsterdam, 1957.

Le brome ayant l'effet inductif le plus accentué produit une attraction plus prononcée sur les électrons extérieurs de l'atome d'oxygène, affaiblissant la liaison O—Tl et facilitant le transfert d'électrons du ^{204}Tl(I) au Tl(III) du complexe. Au point de vue de la possibilité de perturbation des orbitaux électroniques de l'oxygène, le groupement SO_3H aura sans doute un effet plus puissant que celui du I, d'où l'on peut déduire que pour le complexe Tl(III) - acide 8-hydroxyquinoléine-7-sulfonique, l'échange isotopique avec le ^{204}Tl(I) sera plus rapide que pour le complexe Tl(III)-acide 7-iodo-8-hydroxyquinoléine-5-sulfonique.

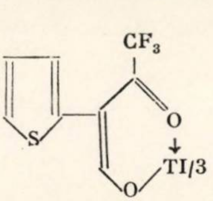
Pour les complexes d'addition entre l'acide tétrabromothallique et les bases pyridiniques ou avec le diantipyrylméthane, on constate que l'échange est plus rapide lorsque dans la molécule organique respective on introduit des substituents CH_3 (α-picoline, 2,6-lutidine, 2, 4, 6-collidine) ou bien un cycle benzénique (quinoléine). L'étude des spectres IR, par exemple, montre que la structure de ces combinaisons complexes est (II)



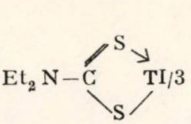
II.

L'addition de l'ion hydrogène à l'azote du cycle pyridinique (ou bien à l'un des atomes d'oxygène dans le diantipyrylméthane) influencera la distribution de la charge positive en l'orientant seulement sur le noyau respectif et non sur les substituents. L'introduction de nouveaux substituents agrandira la distance entre le noyau positif et l'ion négatif $[TlBr_4]^-$, en affaiblissant l'interaction entre les ions. En même temps, l'ion $[TlBr_4]^-$ approchera l'ion $^{204}Tl^+$ en facilitant la réalisation d'un complexe intermédiaire par des ponts de brome, par lesquels le transfert électronique entre les deux états d'oxydation du Tl aura lieu.

Chez les derniers complexes étudiés, on a constaté que l'échange isotopique entre le ^{204}Tl(I) et le Tl(III) complexé avec la thénoyltrifluoroacétone est plus rapide que pour les autres complexes. Ce fait peut s'expliquer par l'attraction plus grande exercée par le noyau du thiophène et surtout par les trois atomes de fluor sur les électrons des orbitaux des atomes d'oxygène, diminuant la densité de charge autour de ces atomes et affaiblissant la liaison entre l'ion métallique central et le ligand (III)



III



IV

Pour le complexe du Tl(III) et le diéthyldithiocarbamate on constate un échange isotopique lent dû aux liaisons C=S et C—S qui, ayant un caractère électronégatif appréciable, attireront les électrons du reste de la molécule organique et agrandiront la stabilité des liaisons S–Tl et S → Tl (IV).

L'échange isotopique pour les complexes avec le dipyridyl et la phénanthroline est très lent puisque, entre les complexes cationiques qu'ils forment avec le Tl(III) et l'ion $^{204}Tl^+$ approchant, il y aura une forte répulsion électrostatique.[22]

On suppose que pour la réalisation du transfert d'électrons il se forme des complexes activés dans lesquels, entre le $^{204}Tl(I)$ et le Tl(III) s'interpose soit une molécule d'eau, soit des ions Br^- ou OH^-.

La probabilité d'existence de ces intermédiaires est différente pour les divers complexes et on peut l'estimer soit par les valeurs de l'entropie d'activation soit par celles du facteur préexponentiel.

Les valeurs élevées de l'entropie d'activation dénotent une très faible stabilité de ces complexes activés, ce qui explique l'échange lent entre les deux états d'oxydation du Tl, tandis que les valeurs plus petites sont associées à une stabilité plus grande des états de transition et à un échange isotopique plus rapide.

Pour les combinaisons complexes coordinatives (neutres ou cationiques), les valeurs des logarithmes du facteur préexponentiel montrent qu'il existe des effets stériques appréciables et que pour réaliser l'état de transition qui facilite l'échange isotopique, il est nécessaire que le réactant non complexé s'approche d'une certaine direction ; si ces conditions ne sont pas satisfaites, la réaction d'échange n'aura pas lieu. Chez les complexes d'addition de l'acide tétrabromothallique avec des bases organiques, il n'y a pas d'effet stérique appréciable et le $^{204}Tl(I)$ peut s'approcher de n'importe quelle direction.

STUDY OF THE THORIUM-PURPURIN COMPLEX BY BUTANOL EXTRACTION

C. DRĂGULESCU, T. SIMONESCU and MARIA TOTAN CURTUI

Ministry of Education, Timişoara Chemical Centre, Bd. Mihai Viteazul 24
"Babeş-Bolyai" University, Faculty of Chemistry, Cluj, str. Arany Janos 11
Timişoara University, str. Pestalozzi 16

Received June 7, 1972

The optimum conditions of thorium extraction with a butanol solution of purpurin in the presence of trichloroacetic acid have been established. The composition and the stability of the complex were determined in butanol medium, the instability constant being $K = 1.02 \cdot 10^{-7}$. The extractive-spectrophotometric method elaborated was used for the determination of thorium from certain alloys and monasitic earths.

Literature references data present purpurin (P) as coloured reagent for aluminium [1] and for germanium colorimetric determination. [2] The complexes of this trihydroxyantraquinonic derivate with rare earths as : La, Ce, Pr, Nd, Sm, were studied spectrophotometrically in 95% ethanol. [3] The composition and stability of certain complexes of thorium with ligands from polyhydroxyantraquinonic derivate series (alizarin, quinalizarin and carminic acid) [4,5] were determined by extractive spectrophotometric methods within the works carried out in our laboratory.

The aim of this paper is to establish the extraction conditions of thorium in the presence of trichloroacetic acid with butanol solution of purpurin, as well as the study of the complex formed in 1-butanol for the elaboration of an extractive spectrophotometric method for the determination of thorium.

EXPERIMENTAL

Apparatus. The absorption spectra were recorded with a SP 800 "Unicam" spectrophotometer, Cambridge, England, and the other spectrophotometric determinations were made with Carl Zeiss Jena DDR "Spekol" spectrophotometer. The pH measurements were made with MV–11 Calmann & Grahnert Dresden DDR pH-meter.

Reagents : 10^{-2}M thorium nitrate solution was prepared dissolving about 5.52 g$Th(NO_3)_4 \cdot . xH_2O$ Merck (with a content of min 46 % ThO_2) in 1.000 ml bidistilled water. The titre of solution was determined gravimetrically as ThO_2.

– $1 \cdot 10^{-3}$ and $2 \cdot 10^{-2}$M thorium nitrate solutions were obtained by dilution.

– $1 \cdot 10^{-3}$ M purpurin solution in 1-butanol was prepared dissolving, by slight heating, 0.0256 g Merck purpurin in 100 ml 1-butanol.

– approx. 2M trichloroacetic acid (TCA) solution was obtained by dissolving a corresponding quantity of Merck trichloroacetic acid in bidistilled water.

– 1-butanol, the fraction between 117 and 118.5° obtained at the distillation of fermentation butanol, was used.

Method

20 ml of butanol solution of purpurin is added to 20 ml aqueous solution containing 0.2 ml about 2 M TCA (pH = 2.5), and a known quantity of thorium nitrate. It is stirred for two minutes and the phases are separated. The butanol phase is collected in a calibrated flask and is completed to 25 ml with 1-butanol. After extraction, thorium content in water solution is determined spectrophotometrically with thoron.[6]

RESULTS AND DISCUSSION

A red-coloured complex is found at extraction of thorium from aqueous solution with a butanol solution of purpurin. Absorption curves of this complex at various pH extractions, in comparison with absorption curves of purpurin in the same conditions are represented in Figure 1. As Figure 1 illustrates, purpurin presents the maximum absorption at 478 nm in the whole pH range in which the determinations were made. The absorption maximum of the thorium-purpurin complex, /Th–P/, is placed at a wavelength much different from that of the pure ligand. Regarding the absorption curve 6 from figure 1 (drawn for optimum extraction condition) the 533 nm wavelength was chosen for determination.

The influence of pH and trichloroacetic acid concentration was studied to establish optimum extraction conditions. The curves in Figure 1 indicate the optimum pH of extraction and formation of the /Th–P/ complex as being 2.5.

There is no /Th–P/ complex formation in pH range 0.6–1.0 and at pH values higher than 3, thorium precipitates, and this makes the determination difficult. Total extraction is practically achieved in the pH range of 2.5–3, after one extraction.

---

[6] M. Pinta "Recherche et dosage des éléments traces" Dunod, Paris, 1962, p. 611.

The percentage distribution curve of thorium depending on trichloroacetic acid concentration represented in Figure 2 shows that the trichloroacetic acid influences much the extraction of thorium with butanol solution of purpurin. In the absence of trichloroacetic acid, a percentage extraction of only 8.6% is obtained.

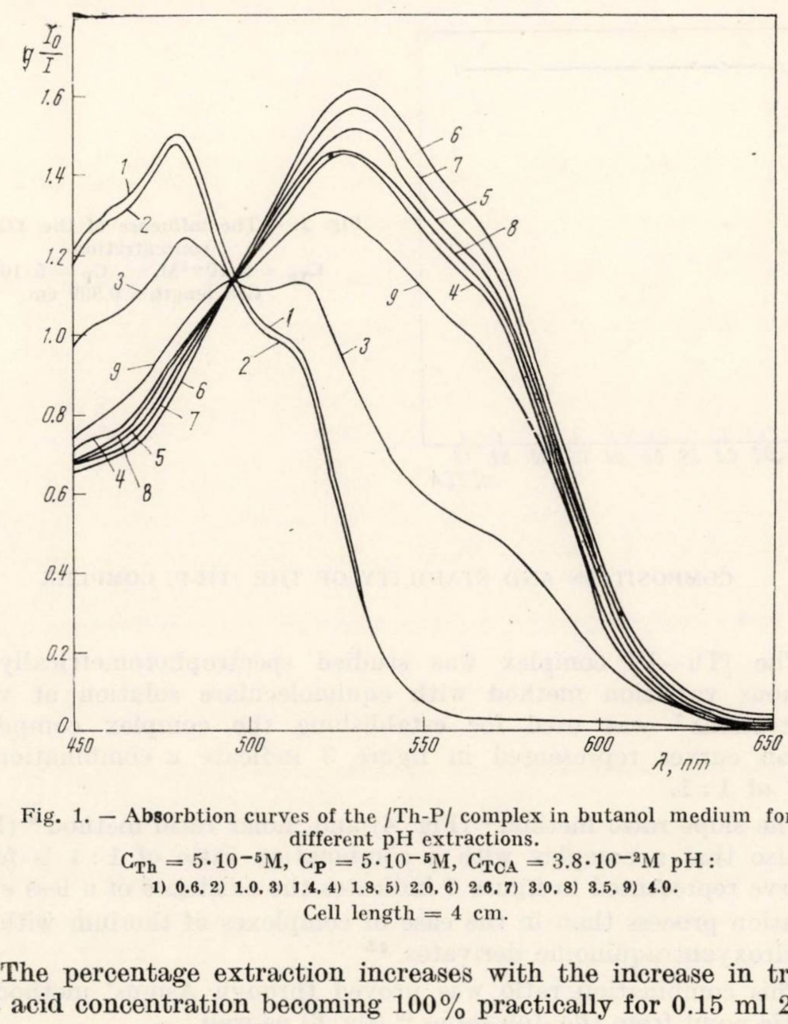

Fig. 1. — Absorbtion curves of the /Th-P/ complex in butanol medium for different pH extractions.
$C_{Th} = 5 \cdot 10^{-5}$M, $C_P = 5 \cdot 10^{-5}$M, $C_{TCA} = 3.8 \cdot 10^{-2}$M pH:
1) 0.6, 2) 1.0, 3) 1.4, 4) 1.8, 5) 2.0, 6) 2.6, 7) 3.0, 8) 3.5, 9) 4.0.
Cell length = 4 cm.

The percentage extraction increases with the increase in trichloroacetic acid concentration becoming 100% practically for 0.15 ml 2M TCA acid in aqueous solution. Since in these conditions the phases are separated very slowly, 0.2 2M TCA acid was used when the phases were well separated.

Following the kinetics of formation reaction of the /Th–P/ complex in 1-butanol, in established extraction conditions, it is noticed that the formation of the complex does not need long time and this allows measurements to be made immediately after the separation of the phases. The complex formed is stable for at least fourteen days.

Lambert Beer's law is observed over the concentration range where the work was carried out. It is observed up to 10 μg at least.

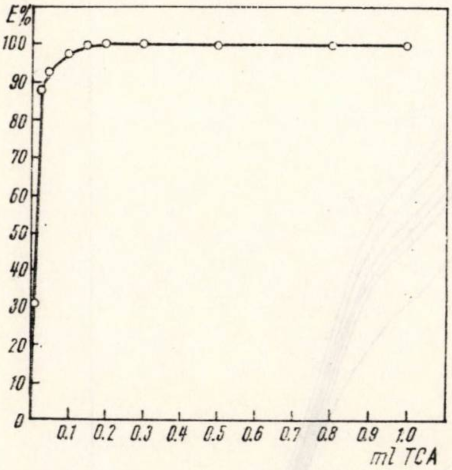

Fig. 2. — The influence of the TCA—acid concentration
$C_{Th} = 5 \cdot 10^{-5}$M, $C_P = 5 \cdot 10^{-5}$ M
Cell length = 0.999 cm.

COMPOSITION AND STABILITY OF THE /TH-P/ COMPLEX

The /Th—P/ complex was studied spectrophotometrically. The continuous variation method with equimoleculare solution at various concentrations[7] was used for establishing the complex composition. The Job curves represented in figure 3 indicate a combination ratio /Th : P of 1 : 1.

The slope ratio method[8] (Fig. 4) and molar ratio method[9] (Fig. 5) show also that a complex with a combination ratio of 1 : 1 is formed. The curve represented in figure 5 indicates the existence of a less evident dissociation process than in the case of complexes of thorium with other polyhydroxyantraquinonic derivates.[4,5]

This combination ratio was proved through Asmus' method with isosbestic point from the Job series[10] (fig. 6) as well.

The instability constant was counted by the method of Harvey and Manning,[8] $K = 1.02 . 10^{-7}$.

EXTRACTIVE SPECTROPHOTOMETRIC DETERMINATION OF THORIUM WITH BUTANOL SOLUTION OF PURPURIN

The spectrophotometric determination of thorium can be made with the aid of a calibration curve, the errors of determination being of 3–5%.

The method was used for the determination of thorium from allyos of composition : Th – 5%, Cu – 30%, Ni – 65%. Ni and Cu do not interfere in this case. At higher concentrations, Cu is masked by complexation with thiourea.

The method was also used for thorium determination from monasitic earths of composition : ThO_2 – 9.8%, U_3O_8–0.29% ; Ce_2O_3 – 27.2%, P_2O_5 – 30.1%, Fe_2O_3 – 0.8%, TiO_2 – 0.4%, and SiO_8 – 8.7%. Exact results are obtained if Si and P are removed as a preliminary.

The determination errors for monasitic earths of higher concentrations in U, Ce, Ti, Fe, are situated between the same limits.

CONCLUSIONS

– The optimum extraction and formation conditions of the /Th–P/ complex were established.

– The trichloroacetic acid makes possible the extraction of thorium with a butanol solution of purpurin in the pH range 2.5–3.

– Percentage extractions of 100% are obtained after one extraction only.

– Lambert-Beer's law is applied up to at least 10.2 μg, and this makes possible the elaboration of the extractive spectrophotometric method for the determination of thorium.

– The equimolecular composition of the complex was established by the continuous variation method, the molar ratio method, the slope ratio method, and the Asmus method with isosbestic point from the Job series.

– The instability constant of the /Th–P/ complex was determined, $K = 1{,}02 \cdot 10^{-7}$.

– The extractive spectrophotometric method elaborated for the determination of thorium was applied successfully to certain alloys and monasitic earths.

URANYL-PYROPHOSPHATE COMPLEXES. III[1] THE MONOPYROPHOSPHATO-PENTAURANYL CATION COMPLEX

C. DRĂGULESCU and NICOLETA VÎLCEANU

Centre of Chemistry
Bd. Mihai Viteazul 24, Timişoara, Romania

Received May 8, 1972

The formation of one single monopyrophosphato-pentauranyl cation complex, $[(UO_2)_5H_2P_2O_7]^{8+}$, was found spectrophotometrically, in the 0.83–3.00 pH range. Its formation constant after the Newman and Hume method is $K_q = 0.0344$.

Literature data concerning the complex combinations of the uranyl cation with oxyacid ligands show that, together with numerous anion-complexes, there are cation complexes as well. Thus, the following combinations have been identified without being separated from the solution: $[(UO_2)_2CO_3]^{2+}$, [2] $[UO_2(SCN)]^+$, [3] $[(UO_2)_2SO_4(H_2O)_{10}]^{2+}$. [4] In the class of pyrophosphate complexes some metal-pyrophosphate cation complexes have been found. These were presented in the monographical work. [5]

Uranyl-pyrophosphate cation complexes have not been mentioned in the previous literature in this field. For the first time this type of combination was mentioned in our work,[6] where we have shown the formation of a series of successive complex combinations in the system $UO_2^{2+} - P_2O_7^{4-}$. The dissolution of the combinations $(UO_2)_2P_2O_7$ and $Na_2(UO_2)_3(P_2O_7)_2$ in an excess of uranyl salt, is an indication for the formation of complexes with a higher proportion of uranyl cation in the molecule.

In the previous note,[6] on the basis of radiometric titration and radioelectrophoretic determinations the possibility of formation of some uranyl-pyrophosphate cation complexes, which can be expressed by the formula $[(UO_2)_mP_2O_7]^{(2m-4)+}$, where $m = 2-5$, was shown.

In order to obtain additional data concerning the formation of the cationic complex combinations, the experimental procedure adopted was the spectrophotometric titration technique. This method permitted the determination of the combination ratio metal-ligand as well as the evaluation of the formation constant of the resulted complex.

EXPERIMENTAL

Reagents :

— $UO_2(NO_3)_2 . 6H_2O$ *p.a.* Merck

— $Na_4P_2O_7 . 10H_2O$ *p.a.* Merck

— $H_4P_2O_7$ *p.a.*, obtained through the passing of a $Na_4P_2O_7$ solution over a Dowex 50 × 12 column.

— The solutions of the different pyrophosphoric species $H_3P_2O_7^-$, $H_2P_2O_7^{2-}$, $HP_2O_7^{3-}$ were prepared from $H_4P_2O_7$ 0.1M and $Na_4P_2O_7$ 0.1M accomplishing mixtures in the proper stoichiometric ratio. The purity of the pyrophosphoric anions was verified through the paper chromatography technique, applying the monodimensional ascendent chromatographic method with acid solvent.[7] The concentration of the pyrophosphoric species has been determined by conductometric or pH-metric titrations with NaOH 0.1M.

— $NaClO_4 . H_2O$ *p.a.* Merck, has been used for the maintaining of the constant strength, $\mu = 0.1$.

Apparatus

— Unicam SP 800 spectrophotometer, with quartz cells;

— pH-meter 25 Radiometer (Copenhagen) with G 202C glass electrode and K 401 calomel electrode.

RESULTS

The spectrophotometric titration of 4×10^{-2} moles $UO_2(NO_3)_2$ with $H_4P_2O_7$ 1×10^{-3}M pH = 1.92 — 0.85, $NaH_3P_2O_7$ 1×10^{-3} M pH = 1.92 — 1.20, $Na_2H_2P_2O_7$ 1×10^{-3} M pH = 1.92 — 1.60 (figures 1 and 2), and $Na_3HP_2O_7$ 1×10^{-3} M pH = 1.92 — 2.40, at the wave length of 420 and 408 mμ, respectively show that irrespective of the reagent, at the molar ratio UO_2^{2+}/pyrophosphoric species = 5/1, the titration curve exhibits a point of inflexion.

The titration of 4×10^{-2} moles $UO_2(NO_3)_2$ with $Na_4P_2O_7$ 1×10^{-3} M pH = 1.92—3.00, leads to a straight line up to the ratio 5/1 between the reaction partners, where the presence of a precipitate stops the titration.

On the other hand, at the molar ratio UO_2^{2+}/pyrophosphoric species = = 5/1 for all the titrations, i.e. on the pH interval between 0.85—3.00, the value of the absorbance is the same for the two wave lengths considered to be ($A = 0.66$ for $\lambda = 420$ mμ and $A = 0.43$ for $\lambda = 408$ mμ). We estimate that those represent proofs for the formation of one single complex at the molar ratio 5/1 between the reagents, to which (taking into consideration the pH of the solutions) the probable composition $[(UO_2)_5H_2P_2O_7]^{8+}$ corresponds.

[8] L. Newman and D. N. Hume, *J. Amer. Chem. Soc.*, **79**, 4571 (1957).

If the ratio K_{q+r}/K_q is sufficiently large it might be necessary to determine K_q when the central atom concentration (M_t) is in great excess to the concentration of the ligand added (X_t). In the case two species are present, out of which one absorbs, at the considered wavelength, the concentration of the complex immediately superior $MX_{q+r} = 0$ and the extinction coefficient of the central ion, $E = 0$, the following relation is applied

$$\log A/E_q = q\{\log(X_t - qA/E_q)\} + \log K_q$$

in which

A — the solution absorbance at the X_t concentration of the ligand added;

q — the molar ratio between the ligand and the metal ion in the complex;

E_q — the extinction coefficient of the complex.

For the monopyrophosphato-pentauranyl cation complex we have determined the formation constant on the basis of the data furnished from the figure 1; $q = 0.2$, $E_q = 21$. Table 1 presents the necessary values for the determination of the formation constant of the monopyrophosphato-pentauranyl cation complex.

Figure 3 contains the determination of the formation constant of the complex $[(UO_2)_5H_2P_2O_7]^{8+}$. The value of the formation constant is $K_q = 0.0344$.

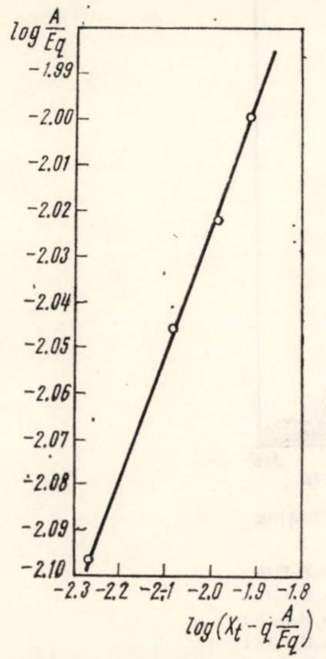

Fig. 3. — Determination of the constant of the complex formation $[(UO_2)_5H_2P_2O_7]^{8+}$.

URANYL-PYROPHOSPHATE COMPLEXES. IV[1]

PRECIPITATION REACTIONS OF THE PYROPHOSPHATO-URANYLATE COMPLEX ANIONS WITH THE Ag^+ ION

C. DRĂGULESCU, NICOLETA VÎLCEANU and I. JULEAN

Centre of Chemistry
Bd. Mihai Viteazul 24, Timişoara, Romania

Received June 11, 1972

The formation of the following complex salts: $Ag_6[UO_2(P_2O_7)_2]$, $Ag_4Na_2[UO_2(P_2O_7)_2]$, $AgNa[UO_2(P_2O_7)]$ and $Ag_2[UO_2(P_2O_7)]$, compounds derived from the bis- and monopyrophosphato-uranylate complex anions, have been evidenced conductometrically and radiometrically.

The titration series of the pyrophosphoric anions with the UO_2^{2+} cation[2] has permitted us, by following the combination ratio of the reaction partners as a pH function, to establish the formation and the composition of the uranyl-pyrophosphate complexes.

For highly soluble complexes that are to be found in the solution, in the form of soluble sodium salts difficult to isolate, we tried an indirect way of checking their composition, by precipitation with salts of heavy metals. In this way, the sodium ions may be either partially or totally replaced by other metallic ions, having a greater ionic radius.

The bis- and monopyrophosphato-uranylate complexes precipitate with a series of metallic ions like: Ag^+, Cd^{2+}, Zn^{2+}, Co^{2+}, Ni^{2+} etc. They may be thus separated from the solution under the form of some still uninvestigated complex salts.

EXPERIMENTAL

Reagents:

- $UO_2(NO_3)_2 \cdot 6H_2O$ *p.a.* Merck
- $Na_4P_2O_7 \cdot 10H_2O$ *p.a.* Merck
- $Na_4{}^{32}P_2O_7$ *p.a.* prepared in the thermic decomposition of $Na_2H^{32}PO_4$ *p.a.* at 550°.

[2] C. Drăgulescu, N. Vîlceanu and I. Julean, *Z. anorg. Chem.*, **376**, 196 (1970).

— The bis- and monopyrophosphato-uranylate complexes were prepared from $UO_2(NO_3)_2$ 0.1M and $Na_4P_2O_7$ 0.1M in stoichiometric ratio.

— $AgNO_3$ *p.a.* and $^{110}AgNO_3$ *p.a.* Merck

— $NaClO_4.H_2O$ *p.a.* Merck

Apparatus

The conductometric titration was effected with a Metrohm-Herisau conductoscop. In the radiometric titration we have used a Vakutronik VAM 16D counter, with Geiger-Müller MTS—17 and VAZ—410 counters.

DISCUSSION OF THE RESULTS

We give below the precipitation titrations of the bis- and mono-pyrophosphato-uranylate complex anions (the paper electrophoretic method has permitted us to put into evidence, by the migration direction of the complexes, only the sign of their charge).

a. The precipitation reaction of the bis-pyrophosphato-uranylate complex anion with the Ag^+ cation.

Figures 1, 2 and 3 show the titration of the bis-pyrophosphato-uranylate complex anion with $AgNO_3$ and vice versa. The conductometric titration curve (curve 1, figure 1) shows a substantial increase in the conductivity of the solution. This is owing to the reagent added. After the addition of about 2 ml $AgNO_3$ 0.1 M there appears a yellow-white voluminous precipitate in the solution. The conductivity of the solution remains constant all along its formation. After reaching the molar ratio of one mole bis-pyrophosphato-uranylate complex to 4 Ag^+ atoms, the conductivity of the solution slowly increases until the mentioned ratio reaches the value 1/6; then the conductivity of the solution registres an important increase depending on the excess of the reagent added.

The curve of the reversed conductometric titration (curve 2, figure 1), shows a very slight increase in the conductibility as far as the molar ratio, complex/Ag^+ = 1/6. From the beginning of the titration one can observe the appearance of the above mentioned voluminous precipitate. The conductivity of the solution continues to increase, function of the excess of the bis-pyrophosphato-uranylate complex added.

The diagram of the radiometric titration of the bis-pyrophosphato-uranylate complex (marked with ^{32}P) with $AgNO_3$ (curve 1, figure 2) shows, in accordance with the analogous conductometric titration, that the formation of the precipitate does not take place immediately, but only after exceeding the solubility of the precipitate. Accordingly, the radioactivity of the solution is constant up to 2 ml reagent addition. The appearance of the precipitate (which engages the marked P atom) is accompanied by a strong decrease of the radioactivity up to the only inflexion point on the titration diagram, corresponding to the molar ratio, complex/Ag^+ = 1/6.

Working with ^{110}Ag and with the unmarked complex (figure 2, curve 2) the radioactivity of the solution increases at the beginning, owing to the marked reagent, but falls with the formation of the precipitate and remains constant during the formation of the precipitate. After the

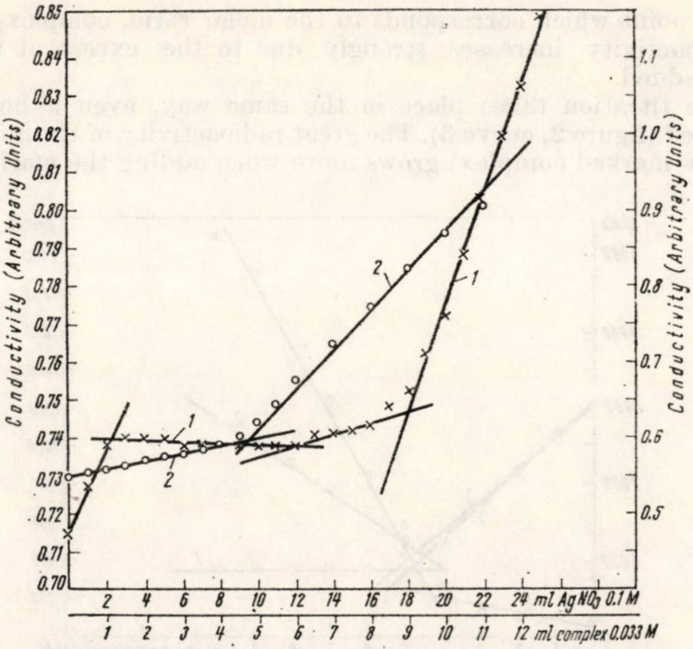

Fig. 1. – Conductometric titration of the sodium bis-pyrophosphato-uranylate complex (3 ml $UO_2(NO_3)_2$ 0.1M + 6 ml $Na_4P_2O_7$ 0.1M) with $AgNO_3$ 0.1M (curve 1). Conductometric titration of 10 ml $AgNO_3$ 0.1M with the sodium bis-pyrophosphato-uranylate complex (prepared from $UO_2(NO_3)_2$ 0.1M and $Na_4P_2O_7$ 0.1M in stoichiometric ratio) (curve 2).

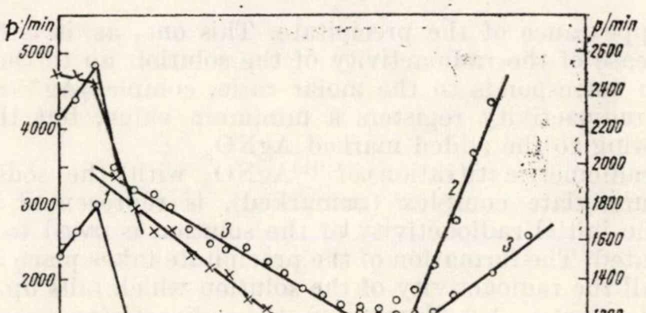

Fig. 2. – Radiometric titration of the sodium bis-pyrophosphato-uranylate complex (3 ml $UO_2(NO_3)_2$ 0.1M + 6 ml $Na_4P_2O_7$ 0.1M) with $AgNO_3$ 0.1M:

1, complex marked with ^{32}P; *2*, $AgNO_3$ marked with ^{110}Ag; *3*, both reaction partners are marked.

inflexion point which corresponds to the molar ratio, complex/$Ag^+ = 1/6$, the radioactivity increases strongly due to the excess of the marked reagent added.

The titration takes place in the same way, even if both reagents are marked (figure 2, curve 3). The great radioactivity of the initial solution (owed the marked complex) grows more when adding the marked reagent, until the appearance of the precipitate. This one, as it is formed, leads to the decrease of the radioactivity of the solution up to the equivalence point which corresponds to the molar ratio, complex/$Ag^+ = 1/6$; in this point, the radioactivity registers a minimum value, but then increases strongly, owing to the added marked $AgNO_3$.

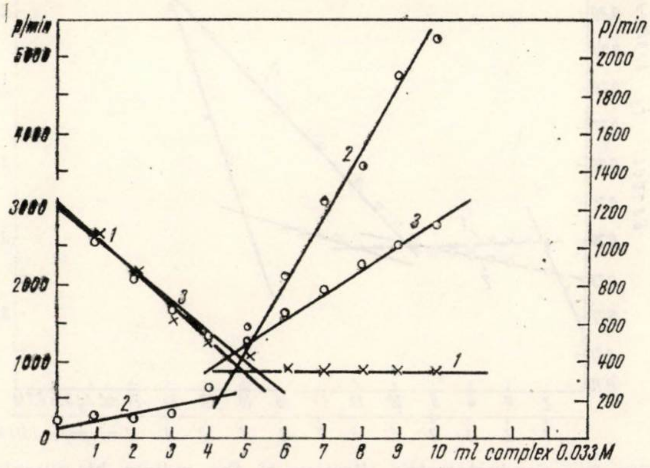

Fig. 3. — Radiometric titration of 10 ml $AgNO_3$ 0.1M with the sodium bis-pyrophosphato-uranylate complex (prepared from $UO_2(NO_3)_2$ 0.1M and $Na_4P_2O_7$ 0.1M in stoichiometric ratio:
1, $AgNO_3$ marked with ^{110}Ag; 2, complex marked with ^{32}P; 3, both reaction partners are marked.

The radiometric titration of $^{110}AgNO_3$ with the sodium-bis-pyrophosphato-uranylate complex (unmarked), is represented by curve 1, figure 3. The initial radioactivity of the solution is owed to ^{110}Ag, which is to be titrated. The formation of the precipitate takes place immediately; it engages all the radioactivity of the solution which falls up to the molar ratio, complex/$Ag^+ = 1/6$. Further on, the radioactivity remains constant.

Working in the variant with unmarked and complex marked $AgNO_3$ (curve 2, figure 3), the curve of the radiometric titration shows a reverse form than the preceding one: the radioactivity is nearly constant, all along the duration of the precipitate formation, until it reaches the same molar ratio, complex/Ag = 1/6, after which it increases strongly (the added complex is marked).

Curve 3 of figure 3 shows the development of the radiometric titration of silver nitrate with sodium bis- pyrophosphato-uranylate complex, both reaction partners being marked. The initial radioactivity of the solution owed to ^{110}Ag decreases when the complex is added, all along the formation period of the precipitate. After the equivalence, marked by the inflexion point which corresponds to the molar ratio, complex/$Ag^+ = 1/6$, the radioactivity registers an important increase in accordance with the marked reagent added.

Comparing the results of the conductometric and radiometric titrations, both direct and reverse ones, in all the investigated variants, we could observe the certain formation of the insoluble combination at the molar ratio, complex/$Ag^+ = 1/6$, corresponding to the $Ag_6[UO_2(P_2O_7)_2]$, after the following scheme :

$$\{[UO_2(P_2O_7)_2]^{6-} + {}_6Na^+\} + {}_6(Ag^+ + NO_3^-) \rightleftarrows$$

$$\rightleftarrows Ag_6[UO_2(P_2O_7)_2] + {}_6(Na^+ + NO_3^-)$$

Unlike all the other titrations, the conductometric titration of the sodium bis-pyrophosphato-uranylate complex with Ag^+ (curve 1, figure 1) also shows the formation of an intermediate compound at the molar ratio, complex/$Ag^+ = 1/4$. In this case the reaction could develop as follows :

$$\{[UO_2(P_2O_7)_2]^{6-} + {}_6Na^+\} + {}_4(Ag^+ + NO_3^-) \rightleftarrows$$

$$\rightleftarrows Ag_4Na_2[UO_2(P_2O_7)_2] + {}_4(Na^+ + NO_3^-)$$

Adding the reagent, the formed precipitate transforms itself in the final product of the reaction $Ag_6[UO_2(P_2O_7)_2]$.

b. The precipitation reaction of the monopyrophosphato-uranylate anion complex with the Ag^+ cation.

Figures 4 and 5 show the precipitation reactions of the sodium monopyrophosphato-uranylate complex with the Ag^+ cation (the reverse titration have not been conclusive and, therefore, we do not present them).

The conductometric titration curve (figure 4) shows an increase in the conductivity of the solution, owing to the reagent added. The compound which is being formed is soluble, at the beginning, until approximately 2 ml $AgNO_3$ is added when the precipitation begins. The first inflexion point of the conductometric curve corresponds to the molar ratio, complex/$Ag^+ = 1/1$. As the reagent is added, the conductivity of the solution increases a little up to the molar ratio 1/2, after which it increases much as the reagent is excessively added.

The radiometric titration curves of the complex marked with Ag^+ (curve 1, figure 5) show, at the beginning, that the radioactivity of the solution is constant and the compound formed is soluble; then it falls owing to the engagement of the complex in the precipitate up to the only equivalence point corresponding to the molar ratio, complex/$Ag^+ = 1/1$.

The same experimental result is obtained by working with marked Ag^+ (curve 3, figure 5). The radioactivity of the solution grows owing to the addition of the marked reagent and formation of the soluble compound.

With the appearance of the precipitate and during its formation, the radioactivity falls strongly up to the molar ratio, complex/$Ag^+ = 1/1$, and then remains constant.

Curve 2, figure 5 shows the evolution of the titration in the case that both reaction partners are marked. In this instant too, the radioactivity of the solution increases owing to the solubility of the formed compound and then suddenly falls. The inflexion point of the diagram at the ratio 1/1 of the components shows the end of the reaction when the radioactivity increases again.

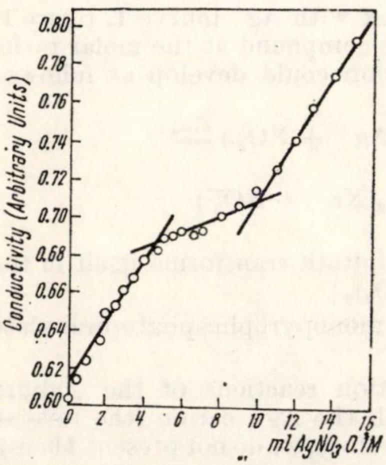

Fig. 4. — Conductometric titration of the sodium monopyrophosphato-uranylate complex (5 ml $UO_2(NO_3)_2$ 0.1M + 5 ml $Na_4P_2O_7$ 0.1M) with $AgNO_3$.

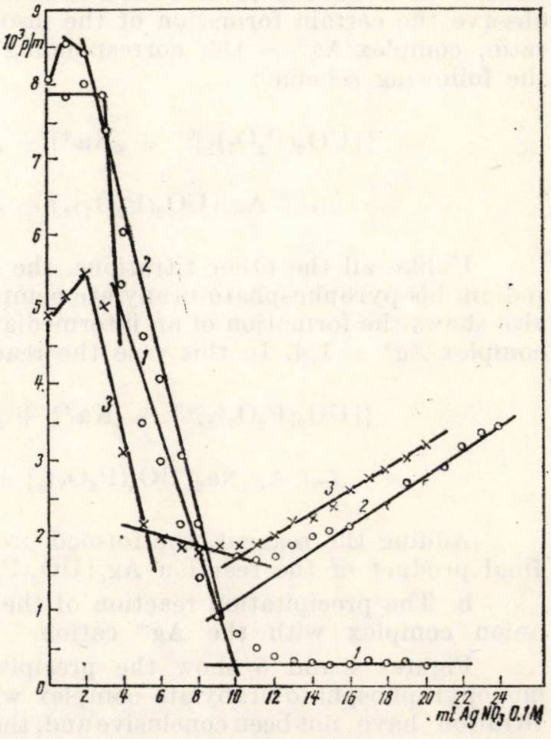

Fig. 5. — Radiometric titration of the sodium monopyrophosphato-uranylate complex (10 ml $UO_2(NO_3)_2$ 0.1M + 10 ml $Na_4P_2O_7$ 0.1M) with $AgNO_3$: *1*, complex marked with ^{32}P; *2*, both reaction partners are marked; *3*, $AgNO_3$ marked with ^{110}Ag.

Both the data of the conductometric titration and the radiometric ones point to the formation of a compound at the molar ratio, monopyrophosphato-uranylate complex/$Ag^+ = 1/1$, $AgNa[UO_2(P_2O_7)]$. Unlike the radiometric titration, the conductometric titration shows that the reaction continues, by replacing the second sodium atom and formation of a compound at the molar ratio, complex/$Ag^+ = 1/2$, $Ag_2[UO_2(P_2O_7)]$.

URANYL-PYROPHOSPHATE COMPLEXES. V[1]

THE PRECIPITATION REACTION OF THE SODIUM BIS-PYROPHOSPHATO-URANYLATE COMPLEX WITH THE Cd^{2+} ION

C. DRĂGULESCU and NICOLETA VÎLCEANU

Centre of Chemistry, Bd. Mihai Viteazul 24, Timişoara, Romania

Received June 11, 1972

The conductometric and potentiometric study of the reaction of sodium bis-pyrophosphato-uranylate complex with $Cd(NO_3)_2$, shows the successive formation of the following combinations:

$Na_2Cd[UO_2(NaP_2O_7)_2]$, $Na_2Cd[CdUO_2(P_2O_7)_2]$ and $Cd_2[CdUO_2(P_2O_7)_2]$.

From the group of divalent metals which precipitated with the sodium bis-pyrophosphato-uranylate complex,[2,3] we have chosen the Cd^{2+} ion for study.

EXPERIMENTAL

Reagents:

- $UO_2(NO_3)_2 \cdot 6H_2O$ *p.a.* Merck
- $Na_4P_2O_7 \cdot 10H_2O$ *p.a.* Merck
- $Cd(NO_3)_2 \cdot 4H_2O$ *p.a.* Merck

Apparatus:

The conductometric titration was effected with a Metrohm Herisau conductoscop.

The potentiometric titration was accomplished with a Radiometer (Copenhagen) pH-meter 25, with a cadmium metallic indicator electrode and a saturated calomel electrode as reference. The titration was made very slowly, with a 40 minutes interval between the readings.

DISCUSSION OF THE RESULTS

Figures 1 and 2 present the conductometric, respectively potentiometric titration of the sodium bis-pyrophosphato-uranylate complex with $Cd(NO_3)_2$.

---

[1] C. Drăgulescu, N. Vîlceanu and I. Julean, Part IV, *Rev. Roumaine Chim.*, **18**, 53–59 (1973).

[2] C. Drăgulescu, I. Julean and N. Vîlceanu, *Rev. Roumaine Chim.*, **10**, 809 (1965).

[3] C. Drăgulescu, N. Vîlceanu and I. Julean, *Z. anorg. Chem.*, **376**, 196 (1970).

The conductometric titration diagram (figure 1), through the three inflexion points, indicated the formation of three combinations at the molar ratio, complex/Cd^{2+} = 1/1, 1/2 and 1/3. All along the titration, the conductibility increases, the segments of the straight line have different slopes.

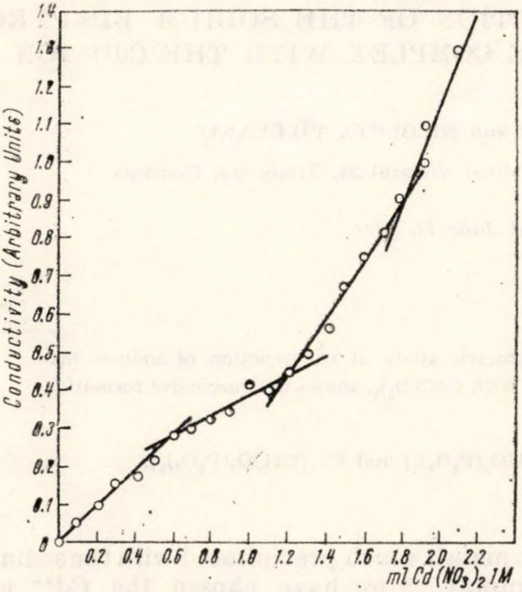

Fig. 1. — Conductometric titration of the sodium bis-pyrophosphato-uranylate complex (6 ml $UO_2(NO_3)_2$ 0.1M + 12 ml $Na_4P_2O_7$ 0.1M) with $Cd(NO_3)_2$ 1M.

The formation of a white-green precipitate takes place immediately but it dissolves again in the solution of the complex. After the addition of 0.3 ml reagent, it appears and maintains all along the titration.

Unlike the conductometric titration of the sodium bis-pyrophosphato-uranylate complex with the Ag^+ ion, [1] which shows the substitution of the six Na^+ ions from the complex $\{[UO_2(P_2O_7)_2]^{6-} + {}_6Na^+\}$ in two stages (at first four and then the last two), the titration with Cd^{2+} shows that the process takes place in three stages, with the gradual substitution of each ${}_2Na^+$ ions with one Cd^{2+} ion.

Through the three equivalent points at the molar ratio, sodium bis-pyrophosphato-uranylate complex/Cd^{2+} = 1/1, 1/2 and 1/3, the potentiometric titration curve shows, in agreement with the conductometric data, the formation of three combinations. Up to equivalence (1), which corresponds to the first potential jump, owing to the fact that the potential of the cadmium electrode is becoming more and more positive, one conclude that there appear Cd^{2+} ions in the system in this part of the titration. After the first equivalence, as the potential of the cadmium electrode becomes more and more negative, it seems that the Cd^{2+} ions disappear gradually from the system (equivalence (2)). The third point of equivalence may be interpreted in the same way as the first one.

The potentiometric titration curve permits the following interpretation for the processes that take place :

In the first stage of the reaction there is an ionic change in the external sphere of coordination of the complex between two Na^+ ions and one Cd^{2+} ion.

In the second part of the reaction (up to equivalence (2)), the titration diagram shows that a slow process of captivating the Cd^{2+} begins, by engaging them in the internal sphere of the complex, where a Cd^{2+} ion replaces two Na^+ ions. Such a behaviour is in accordance with the results obtained by Lambert and Watters[4] which show that at $pH > 8.87$ one must take into consideration the formation of the $[Na(P_2O_7)]^{3-}$ complex.

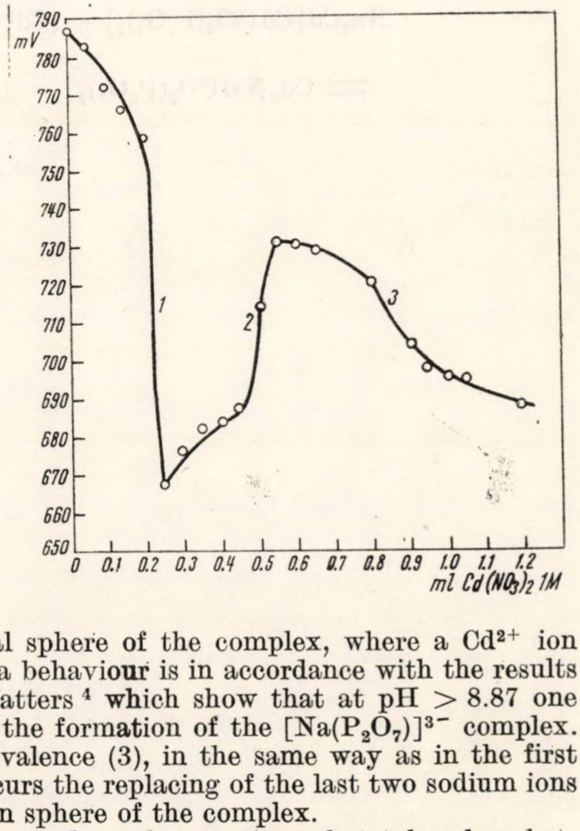

Fig. 2.—Potentiometric titration of the sodium bis-pyrophosphato-uranylate complex (3 ml $UO_2(NO_3)_2$ 0.1M + 6 ml $Na_4P_2O_7$ 0.1 M) with $Cd(NO_3)_2$ 1M.

In the end, up to equivalence (3), in the same way as in the first part of the titration, there occurs the replacing of the last two sodium ions from the external coordination sphere of the complex.

We may schematically reproduce the reactions that take place between the sodium bis-pyrophosphato-uranylate complex and Cd^{2+} ions as follows :

— up to equivalence (1) :

$$\{_4Na + [UO_2(NaP_2O_7)_2]^{4-}\} + (Cd^{2+} + {}_2NO_3^-) \rightleftarrows$$

$$\rightleftarrows Na_2Cd\,[UO_2(NaP_2O_7)_2] + {}_2(Na^+ + NO_3^-)$$

---

[4] S. M. Lambert and J. I. Watters, *J. Amer. Chem. Soc.*, **79**, 4262 (1957).

— up to equivalence (2) :

$$Na_2Cd[UO_2(NaP_2O_7)_2] + (Cd^{2+} + {}_2NO_3^-) \rightleftarrows$$

$$\rightleftarrows Na_2Cd[CdUO_2(P_2O_7)_2] + {}_2(Na^+ + NO_3^-)$$

— up to equivalence (3) :

$$Na_2Cd[CdUO_2(P_2O_7)_2] + (Cd^{2+} + {}_2NO_3^-) \rightleftarrows$$

$$\rightleftarrows Cd_2[CdUO_2(P_2O_7)_2] + {}_2(Na^+ + NO_3^-)$$

SCHIFF BASE COMPLEXES WITH IV AND V GROUP METALS

N. S. BIRADAR * and V. H. KULKARNI
Department of Chemistry, Karnatak University, Dharwar, India

Received April 28, 1972

A few IV and V group metal complexes have been prepared with bis (salicylidene-4-aminoacetophenone)-benzidine and bis(salicylidene-4-aminoacetophenone)-*p*, *p*'-diaminodiphenyl sulphide, and characterized by elemental analysis. They are yellow to orange-yellow coloured amorphous substances, insoluble in common organic solvents. The infrared spectra of these complexes have been studied, and possible structures have been proposed.

INTRODUCTION

The bidentate Schiff bases containing a variety of donor sites are numerous, and the complexes with those bases rank among the most studied and best characterized ones.[1-4] Recently, in an exhaustive review on the multidentate chelating agents, Goodwin [5] gives a critical account of various designs of the multidentate Schiff bases, and the steric-factors influencing the geometry of the ligands. However, in these recent years, Broomhead, Robinson [6] and Wilson, Rose [7] synthesized, and characterized a new heptadentate Schiff base and its nickel (II) complex.

All these observations establish that there is no much information available on the multidentate Schiff base complexes of IV and V group metals. It is of interest to study the stereochemistry of these metals when complexed with various multidentate Schiff bases.

In this paper we wish to report the synthesis and characterization of the IV and V group metal complexes with the following new Schiff bases.

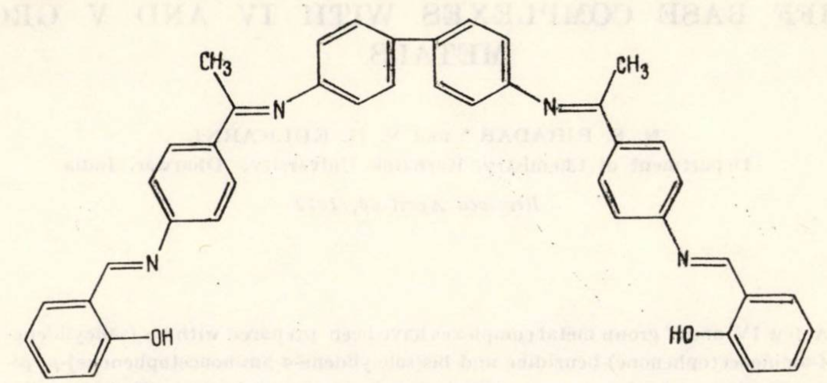
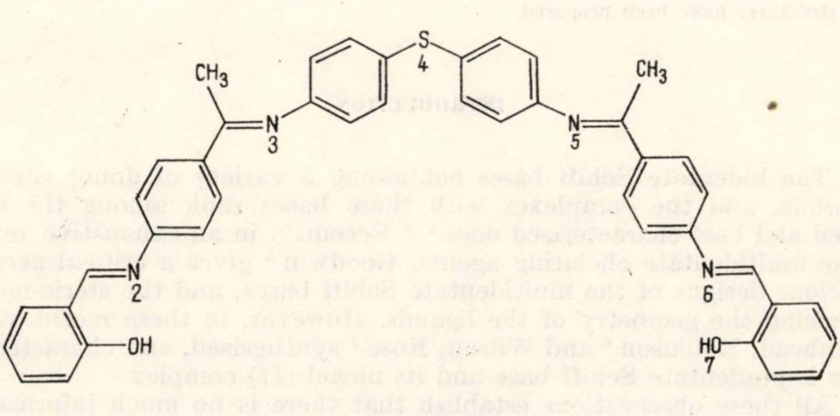
I. Bis-(salicylidene-4-aminoacetophenone) benzidine
II. Bis-(salicylidene-4-aminoacetophenone)-*p*, *p*′-diaminodiphenyl sulphide.



I



II

EXPERIMENTAL

Tin (IV) and titanium (IV) chlorides and zirconyl chloride were of Riedel grade. Niobium (V) chloride was of Fluka grade. Oxovanadium (V) chloride was prepared by the known method.[8] *p*, *p*′-diaminodiphenyl sulphide was prepared by the method reported elsewhere.[9]

PREPARATION OF THE SCHIFF BASES

Salicylaldehyde and 4-aminoacetophenone in 1 : 1 molar ratio were refluxed for an hour on a water bath. The reaction mixture was cooled and salicylidene-4-aminoacetophenone was separated.

---

[8] G. Brauer, "Handbook of Preparative Inorganic Chemistry" Vol. 2; Academic Press, New York, 1965, p. 1264.

[9] S. R. Safir, S. Kushner L. M. Braucone and Y. Subbaraw, *J. Org. Chem.*, 13 924 (1948).

Further, salicylidene-4-aminoacetophenone and a diamine (benzidine or *p, p'*-diaminodiphenylamine) were mixed in 1 : 2 molar ratio in a large excess of alcohol and refluxed for two hours. The solid separated was filtered, washed with alcohol and dried in vacuum over fused calcium chloride.

PREPARATION OF THE COMPLEXES

1. *Tin (IV) Complex* : Tin (IV) chloride in absolute alcohol was mixed with a little excess of Schiff base in an alcohol medium and refluxed for 3–4 hours at 70–80°. The solvent was vapourized away and consequently the temperature was raised to 180° and maintained around 180° till the HCl gas ceased to evolve. The solid formed was extracted with alcohol and filtered. The dry mass was powdered and extracted in a Soxhlet apparatus using absolute alcohol.

	% Sn	% N	% Cl	
1. $(C_{42}H_{32}N_4O_2)SnCl_2$	14.45	6.92	8.52	Found
	14.59	6.88	8.72	Calcd.
2. $(C_{42}H_{32}SN_4O_2)SnCl_2$	13.94	6.70	8.25	Found
	14.03	6.62	8.40	Calcd.

2. *Titanium (IV) complex* : The same procedure as above was followed to prepare this complex :

	% Ti	% N	% Cl	
3. $(C_{42}H_{32}N_4O_2)TiCl_2$	6.35	7.60	9.45	Found
	6.45	7.54	9.56	Calcd.
4. $(C_{42}H_{32}SN_4O_2)TiCl_2$	6.00	7.32	9.00	Found
	6.18	7.23	9.16	Calcd.

3. *Complex with* $ZrOCl_2$: The method for preparing these complexes is reported elsewhere.[10]

	%Zr	%N	%Cl	
5. $(C_{42}H_{32}N_4O_2)ZrCl_2$	11.53	7.20	8.97	Found

	11.15	6.84	8.68	Calcd.

4. *Oxovanadium (V) complex* : $VOCl_3$ in carbon tetrachloride was treated with a slight excess of Schiff base with vigorous shaking and left for several hours till the evaluation of HCl gas ceased. The precipitated complex was filtered and washed with carbon tetrachloride and finally with ether. The dry mass was powdered and extracted in a Soxhlet apparatus till it was free from the reagent, then washed with ether and dried at 50–60°.

	% V	% N	% Cl

	10.86	6.55	12.46	Calcd.

ANALYSIS

Metal ions, chloride and nitrogen in these complexes were determined by the standard methods.[11]

PHYSICAL MEASUREMENTS

Details of the physical measurements are the same as those given in our previous paper.[12]

RESULTS AND DISCUSSION

All the complexes are yellow in colour, amorphous and insoluble in almost all common organic solvents. They are soluble to a limited extent in DMF and DMSO.

The molar conductance values in DMF at the concentration 10^{-3} M show that these are non-electrolytes in DMF.

The base I contains four C=N, and two OH groups. The infrared spectrum of salicylidene-4-aminoacetophenone shows a strong band at 1690 cm^{-1} and it is attributed to the C=O stretch. It is known that C=O group shows a strong band around 1705 cm^{-1} and it is sensitive to the conjugation.[12] In the Schiff base I this band disappears and the band due to the C=N stretch appears around 1590 cm^{-1}. This suggests clearly that the C=O group of the salicylidene-4-aminoacetophenone has been utilized in the reaction with the NH_2 groups of the benzidine. This base can be compared with the typical hexadentate ligand III reported by Sarma and Bailar,[13] bis (salicylidene) trithylenetetramine.

On the grounds of steric factors they have shown that the Schiff base III prefers the configuration IV.

The Schiff base under present investigation is of aromatic origin and possesses all the coordinating sites on the *para* positions and only two peripheral hydroxy groups are on the *ortho* positions. This makes the molecule bulky, and the coordination groups on the *para* positions promote the steric hindrance. It can generate O—N—N and N—N—O sequences which are necessary for the sexadentate behaviour. But the mode of situation of the donor groups shows that the molecule is very much strained to act as a sexadentate ligand.

These chlorides of group IV and V metals form complexes with 1 : 1 stoichiometry with this base and these are all non-electrolytes.

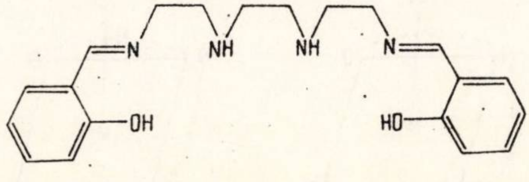
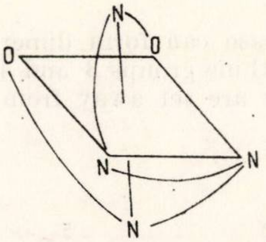
[12] N. S. Biradar and V. H. Kulkarni, *J. Inorg. Nuclear Chem.*, **33**, 2451 (1971).

[13] B. Das Sarma and J. C. Bailar Jr., *J. Amer. Chem. Soc.*, **77**, 5476 (1955).

The infrared spectrum of the ligand I shows an intense band at 1590 cm^{-1} and is assigned to the mixture of C=N and C=C stretching vibrations. This band splits into two bands on complex formation and one band appears around 1613 cm^{-1} and the other appears around 1587 cm^{-1}. The band at higher frequency is attributed to the C=N stretch in the complexes. The broad, weak band assignable to the intramolecular hydrogen bonded-OH disappears in the complexes, showing that the oxygen metal bonds have been formed between metals and the ligand.



III



IV

It has been established that the metal ligand vibrations occur in the 600—400 cm^{-1} region.[14] The *trans* complexes are shown to have only one ν(M — N) vibration while the *cis* complexes show two ν(M — N) vibrations. [15] The titanium (IV) complex shows two bands in the region 550—530 cm^{-1} and are assigned to the ν(Ti—N) vibrations. This suggests that the complex favours the *cis* configuration.

From the above discussion, it can be concluded that the hydroxy groups 1 and 6 are involved in the complex formation and azomethine groups are coordinated to the central metal ion. This information helps to predict structures VA, B for these complexes.
The construction of the model shows that the molecule is flexible enough to allow the azomethine groups 2 and 5 and hydroxy groups 1 and 6 to take part in the complexation, to result the complex of the type (A). If the azomethine groups 3 and 4 form coordinate bonds with the central metal ion (as shown in B), it requires the stabilization of the twelve membered rings instead of two six-membered rings (as shown in A). In addition to this the *para* — azomethine groups 3 and 4 in the molecule present

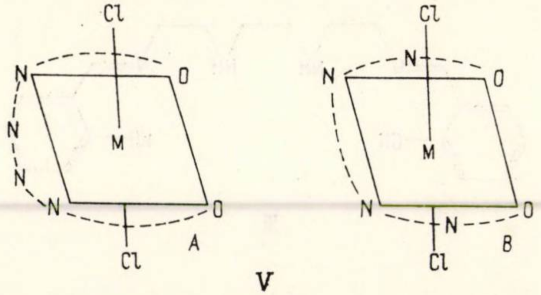
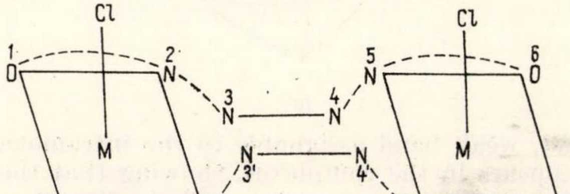
the added steric hindrance, thus preventing the formation of alternate structure (B).

It may be thought that like bis (salicylidene) benzidine, which fails to form monomeric complexes on the grounds of steric-factors, and forms



V

dimeric complexes, this base can form dimeric complexes of type C. In this case also the azomethine groups 3 and 4 may not take part in the complex formation as they are set away from the position suitable for coordination.



C

It seems possible in view of the known dimeric complexes of bis (salicylidene) benzidine [16,17] and other similar type of Schiff bases [18,19].

The complex of oxovanadium (V) with this base shows two distinct IR bands in the V=O stretching region, indicating that the complex exists in the dimeric form. Ginsberg *et al.* [20] also notice such type of doubling in the case of oxovanadium (IV) complexes with substituted salicylidene-*o*-aminophenols. It has already been shown that the base favours to form *cis* complexes, analogous to bis (salicylidene) benzidine and bis (salicylidene)-*p*-phenylenediamine.

This discussion helps us to realize that the IV group metal complexes with this ligand prefer to exist in the *cis* dimeric structure having coor-

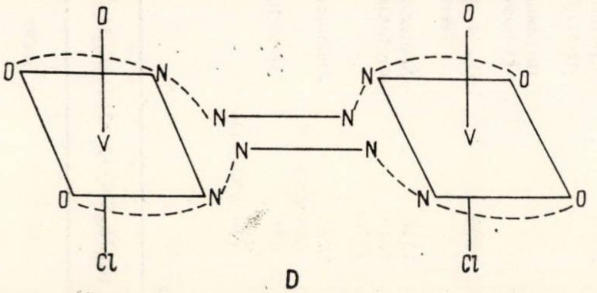
[20] A. P. Ginsberg, E. Koubeck and H. J. Williams, *Inorg. Chem.*, **5**, 1656 (1966).

dination number six. Two chlorides occupy the *trans* positions in the octahedron. In the case of oxovanadium (V) the coordination number is six, and the *trans* positions are occupied by the oxygen and chloride (type D).



D

Niobium (V) forms 1 : 1 complex and it has lost two of its five chlorides in the reaction. It is shown to be non-electrolyte in DMF, hence the complex has coordination seven. There is no simple arrangement known for this coordination number. But in view of the majority of the known complexes having 1 : 4 : 2 stereochemistry [21] these complexes may be regarded to have this stereochemistry.

The condensation of salicylidene-4-aminoacetophenone with *p*, *p'*-diaminodiphenyl sulphide yields the Schiff base II.

This base contains seven hetero-atoms positioned in appropriate places required for the coordination. Two hydroxy groups (1 and 7), four azomethine groups (2, 3, 5 and 6) and one sulphur group (4) present in the molecule make us include this base in the heptadentate ligand group. It can be said that the pyramidal disposition of the sulphur bonds removes the steric hindrance to some extent. The base II is comparatively more flexible than the base I. Like base I, this base also contains all the coordinating centres on the *para* positions.

The IR spectrum of the base shows a strong band at 1626 cm^{-1} and is assigned to the C=N stretch. This band shows considerable shift on complexation (Table 1) suggesting that the coordination has formed between the metal ion and the azomethine nitrogen. The band due to intramolecular hydrogen bonded —OH is not observed in the complexes.

From the above observations it is possible to propose the two structures *E* and *F* for these complexes :
In both cases the central —S— is removed far away from the position suitable for coordination. The steric hindrance does not permit the azomethine groups 3 and 5 to take part in the coordinate bond formation.

The IR spectrum of oxovanadium (V) shows double bands in the V=O stretching region (Table 1), and titanium (IV) complex shows two bands in the ν(M—N) region (Table 1) showing that the complex favours the *cis* form. These observations help us to conclude that all the complexes with this base II can exist in the dimeric form (G).

L'ÉTUDE DES ESPÈCES IONIQUES FORMÉES PAR L'HYDROLYSE DE L'ION D'URANIUM HEXAVALENT

MARIA MAVRODIN-TĂRĂBÎC

Centre de Chimie Physique, 31, str. Galaţi, Bucarest

Reçu le 2 février 1972

On a déterminé, par des méthodes spectrophotométriques et pH-métriques, la nature et la stabilité des espèces ioniques formées par l'hydrolyse de l'ion d'uranium hexavalent, en milieu inerte d'acide perchlorique. On a démontré que, dans un domaine de pH supérieur à 2,5, l'hydrolyse de l'ion UO_2^{2+} a lieu par une suite de réactions qui dépendent du pH et qui conduisent à la formation des complexes polynucléaires du type $U_2O_5^{2+}$ et $U_3O_8^{2+}$, caractérisés par les valeurs moyennes des constantes d'équilibre $K_1 = 1 . 10^{-6}$ et $K_2 = 1 . 10^{-7}$.

Les études effectuées sur les solutions des sels d'uranium hexavalent ont démontré que l'ion U^{6+} n'existe pas dans les solutions aqueuses. Même dans les solutions les plus acides c'est exclusivement l'ion UO_2^{2+} qui se forme, celui-ci pouvant être considéré comme un premier terme d'une série de produits d'hydrolyse.[1–3]

La détermination et la caractérisation des espèces ioniques qui résultent de l'hydrolyse des sels d'uranium hexavalent est très importante, tant au point de vue pratique — vu le rôle que cet élément joue dans les différents domaines de la science appliquée et la technique moderne — qu'au point de vue théorique, étant donné la complexité des réactions qui ont lieu dans les systèmes : « sels d'uranium hexavalent — eau». L'importance de l'étude est illustrée par le grand nombre de travaux publiés, ces derniers temps, dans ce domaine.[4–16]

Les recherches entreprises en vue d'éclaircir le mécanisme de l'hydrolyse n'ont pas réussi à déterminer complètement la composition du système à cause de la complexité des réactions et du grand nombre des espèces ioniques théoriquement possibles, dont la formation est conditionnée par une série de paramètres du milieu tels que : pH, concentration, température, nature des ions qui coexistent dans la solution, force ionique, etc.

Vu que les conclusions auxquelles ont abouti les différents chercheurs sont souvent contradictoires, l'étude des réactions qui ont lieu dans les systèmes « sel d'uranium hexavalent — eau » reste encore très actuelle.

★

Compte tenu des considérations ci-dessus, dans ce travail on s'est proposé de :

— déterminer la nature des espèces ioniques résultant de l'hydrolyse de l'uranium ;

— caractériser l'évolution des réactions mises en évidence en fonction d'une série de paramètres du milieu tels que : pH, force ionique, concentration, nature des ions coexistant dans la solution, etc.

L'analyse qualitative de la nature des réactions qui ont lieu dans les systèmes : « sel d'uranium hexavalent — eau » a été faite par voie spectrophotométrique, l'étude quantitative des réactions mises en évidence s'effectuant à l'aide des titrages pH-métriques.

Pour éviter les erreurs, les études ont été réalisées en utilisant du perchlorate d'uranyle, étant donné que l'ion UO_2^{2+} ne forme pas de complexes avec l'ion ClO_4^-.

PARTIE EXPÉRIMENTALE

RÉACTIFS

Perchlorate d'uranyle, $UO_2(ClO_4)_2\ 6H_2O$ (*p.a.* Th. Schuchardt). On a préparé une solution « stock » approximativement 0,1 N, dont on a obtenu, en diluant avec de l'eau bidistillée, les solutions de perchlorate d'uranyle de différentes concentrations : 0,02 N, 0,05 N, 0,01 N, 0,001 N.

Les concentrations de ces solutions ont été vérifiées par voie gravimétrique (évaporation et calcination à l'état d'oxyde U_3O_8).

— *Perchlorate de sodium*, $NaClO_4$ (*purum*, Merck). Il a été utilisé après trois recristallisations et séchage à 110°.

— *Hydroxyde de sodium* (*p.a.* Merck). Les solutions utilisées ont été préparées en diluant une solution « stock » approximativement 0,1 N. La concentration des solutions de NaOH a été établie avec du phtalate acide de kalium.

— *Acide perchlorique*, $HClO_4$ (*p.a.* Merck) de concentration d'environ 75 %. On a utilisé des solutions approximativement 0,1 N, analysées par titrage alcalimétrique.

APPAREILS

Les déterminations spectrophotométriques ont été effectuées à l'aide d'un spectrophotomètre Karl Zeiss Jéna VSU 1.

Pour les titrages pH-métriques on a utilisé un pH-mètre Radiometer – Copenhagen (électrodes de verre et calomel). Les déterminations ont été faites dans une installation fermée spécialement construite.

MODE DE TRAVAIL

L'étude spectrophotométrique a été effectuée en déterminant les courbes d'absorption des solutions de perchlorate d'uranyle à :

a) *concentration constante* (0,02 N) et pH variable (1,6 ; 2 ; 2,5 ; 3 et 4) – pour tirer des conclusions en ce qui concerne l'évolution de l'hydrolyse en fonction du pH – et à

b) pH constant (1,6) et concentration variable (0,02 ; 0,04 et 0,01 M) – pour tirer des conclusions sur la nature des composés–résultant de l'hydrolyse, en fonction de la concentration.

Les différentes valeurs du pH ont été obtenues en ajoutant de l'acide perchlorique, respectivement de l'hydroxyde de sodium. Les solutions ont été maintenues à une force ionique constante $I = 1$, en utilisant comme milieu ionique le perchlorate de sodium. Les déterminations ont été faites à une température d'environ 22°.

Les *déterminations pH-métriques* ont été effectuées en titrant les solutions d'uranyle avec du NaOH. Pour tirer des conclusions sur l'influence de la concentration sur la nature des espèces ioniques qui se forment par l'hydrolyse, on a travaillé avec des solutions de perchlorate d'uranyle de différentes concentrations, comprises entre 0,1 – 0,001 M.

L'influence de la force ionique a été évaluée en effectuant des déterminations, pour chaque concentration, à quatre forces ioniques : I = 0,5 ; 1 ; 1,5 et 2, réalisées avec du $NaClO_4$.

Les déterminations ont été faites par le titrage direct de la solution de perchlorate d'uranyle avec du NaOH. On a travaillé dans un large domaine de pH, les titrages pH-métriques étant considérés terminés à l'apparition d'un précipité stable, de couleur orange, de polyuranate. Les titrages ont été répétés trois fois, les valeurs du pH représentées graphiquement et utilisées dans les calculs étant des valeurs moyennes. Les valeurs d'équilibre ont été obtenues après 60 secondes d'agitation.

RÉSULTATS ET DISCUSSIONS SUR LA NATURE ET LA STABILITÉ DES ESPÈCES IONIQUES FORMÉES PAR L'HYDROLYSE DE L'ION U^{6+}

1. L'ÉTUDE SPECTROPHOTOMÉTRIQUE

La formation des produits d'hydrolyse, en fonction du pH, a été mise en évidence qualitativement en déterminant les courbes d'absorption caractéristiques de la solution de perchlorate d'uranyle à différentes valeurs du pH.

Tel qu'on le voit dans la figure 1, les courbes d'absorption obtenues au pH =1,6 ; 2 et 2,5 sont identiques, ce qui confirme que, dans ce domaine de pH, il ne se forme qu'un seul ion, l'ion UO_2^{2+} ; au pH = 3, on obtient une courbe d'absorption évidemment déviée, ce qui indique un déplacement de l'équilibre dans le sens de l'hydrolyse de l'ion UO_2^{2+}, qui commence au pH 2,5 et continue, en s'accentuant, à mesure que le pH de la solution augmente. Des courbes d'absorption représentées dans la figure 1, on constate que les espèces ioniques formées par l'hydrolyse de l'ion UO_2^{2+} (pH $> 2,5$) se caractérisent par des coefficients molaires d'extinction supérieurs à celui de l'ion UO_2^{2+}.

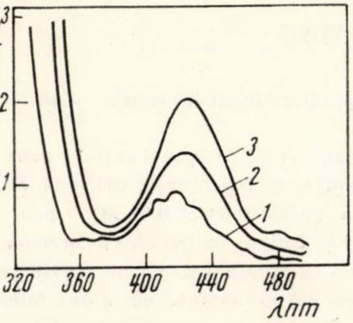

Fig. 1. — Variation du spectre d'absorption de la solution de perchlorate d'uranyle 0,01 M, en fonction du pH. courbe *1* : pH = 1,6 ; 2 et 2,5 ; courbe *2* : pH = 3, courbe *3* : pH = 4)

Le fait que, à un certain pH, l'allure des courbes d'absorption est identique pour toutes les concentrations considérées, écarte l'hypothèse de la formation des produits polymères du type $(UO_2)_2$, $(UO_2)_3 \ldots (UO_2)_n$.

2. L'ÉTUDE pH-MÉTRIQUE

2.1. LA DÉTERMINATION DE LA NATURE DES ESPÈCES IONIQUES FORMÉES PAR L'HYDROLYSE

L'étude quantitative des équilibres hydrolytiques du système : « perchlorate d'uranyle — eau » a été effectuée par le titrage pH-métrique des solutions de perchlorate d'uranyle, caractérisées par des concentrations variant entre 0,001—0,05M et par les forces ioniques $I = 0,5$; 1 ; 1,5 et 2.

Les données expérimentales obtenues en travaillant dans le domaine de pH $= 2,5-10$ sont représentées dans les figures 2—5.

En analysant les courbes de titrages des solutions de perchlorate d'uranyle on observe que :

— L'allure générale des courbes est semblable, à toutes les concentrations et forces ioniques, ce qui indique que, dans le domaine de concentration considéré (0,05—0,001 M), la nature des réactions qui ont lieu dans le système est la même.

— Les courbes de titrage présentent deux points d'inflexion situés au pH $= 4,5-5$ et, respectivement, au pH > 6. Ces deux points d'inflexion correspondent à des valeurs du pH qui varient avec la concentration des solutions considérées, mais leur propriété caractéristique est que le rapport : mol. UO_2^{2+} : équivalents de NaOH correspondant à la première inflexion : équivalents de NaOH correspondant à la seconde inflexion est le même pour toutes les concentrations et les forces ioniques : 1 : 1,68 ; 2,36 ou 3 : 5 : 7.

Les équivalents de NaOH ont été calculés aux points d'inflexion, déterminés — pour toutes les concentrations et forces ioniques — à l'aide

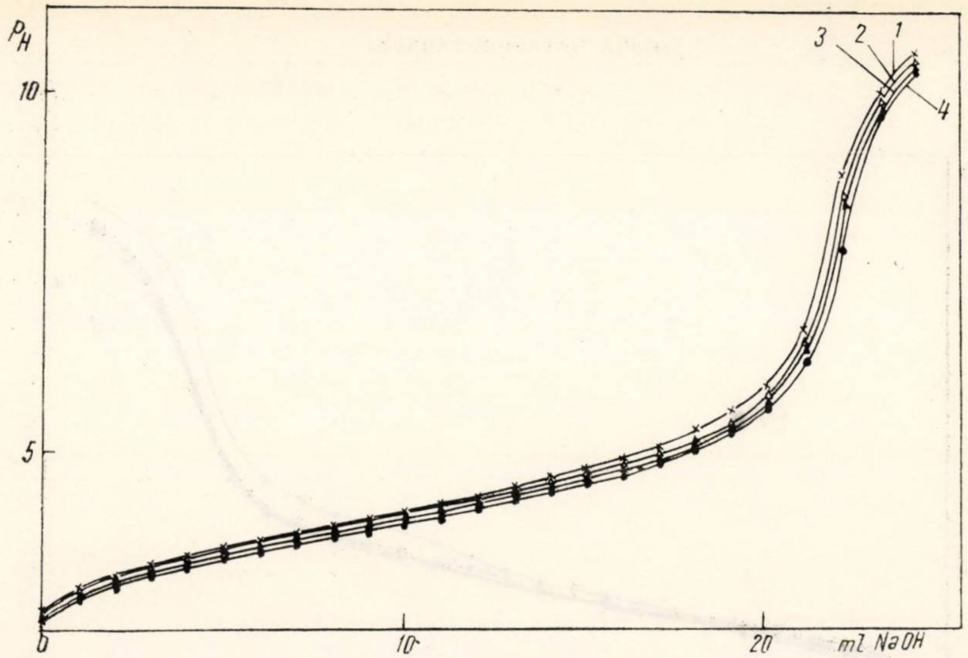

Fig. 2. — Courbes de titrage pH-métrique des solutions de perchlorate d'uranyle 0,05 M (I = 0,5 (*1*);
I = 1 (*2*); *I* = 1,5 (*3*); *I* = 2(*4*)).

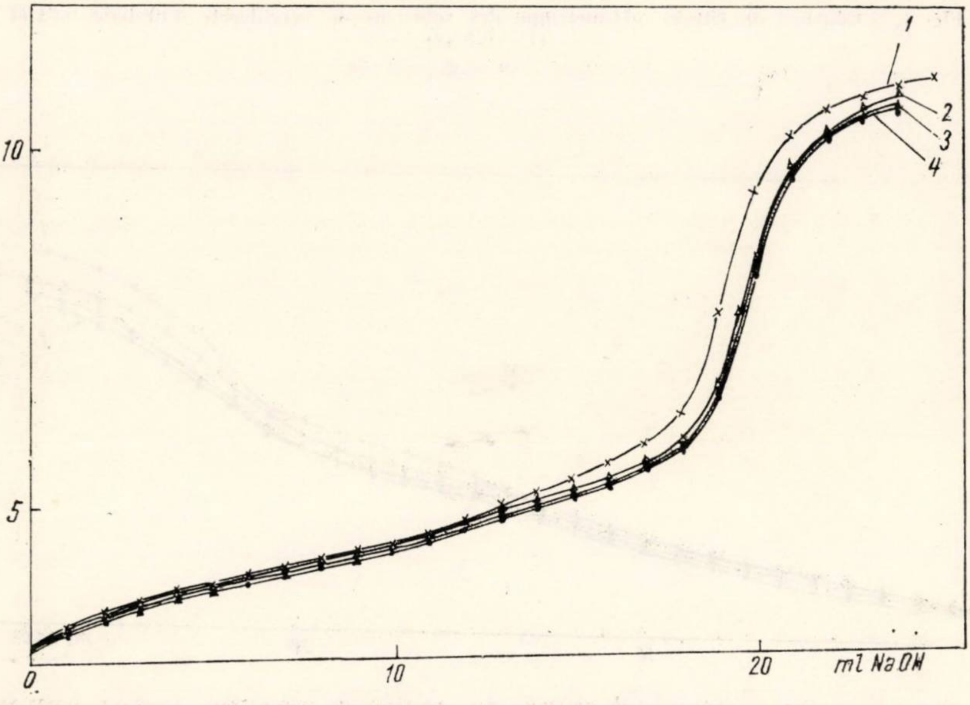

Fig. 3. — Courbes de titrage pH-métrique des solutions de perchlorate d'uranyle 0,02 M (I = 0,5 (*1*);
I = 1 (*2*); *I* = 1,5 (*3*) et *I* = 2 (*4*)).

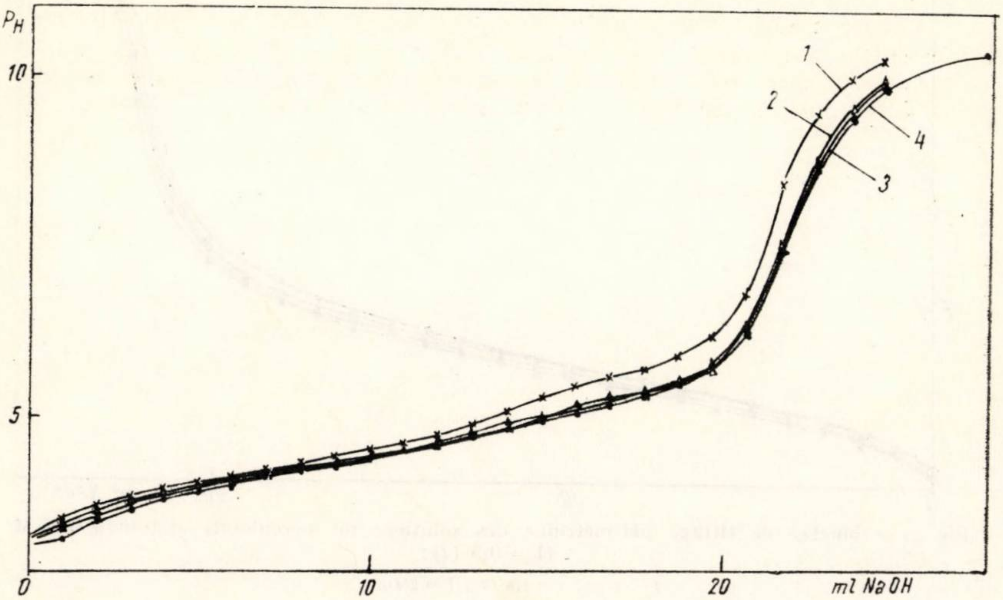

Fig. 4. — Courbes de titrage pH-métrique des solutions de perchlorate d'uranyle 0,01 M ($I = 0,5$ (*1*);
$I = 1$ (*2*); $I = 1,5$ (*3*) et $I = 2$ (*4*)).

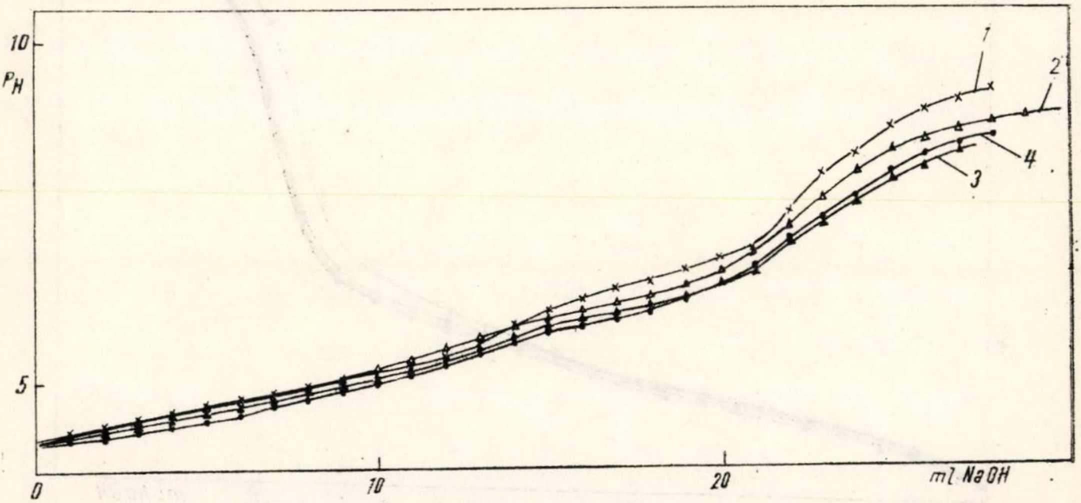

Fig. 5. — Courbes de titrage pH-métrique des solutions de perchlorate d'uranyle 0,001 M ($I = 0,5$ (*1*);
$I = 1$ (*2*); $I = 1,5$ (*3*) et $I = 2$ (*4*)).

des courbes différentielles. (Dans la figure 6 on a représenté quelques-unes de ces courbes.)

Les rapports $UO_2^{2+} : OH^- = 3 : 5 : 7$ indiquent que les réactions d'hydrolyse impliquent trois ions UO_2^{2+} et cinq ions OH^- (pour la première inflexion) et trois ions UO_2^{2+} et 7 ions OH^- (pour la deuxième inflexion) et plaident pour un mécanisme d'hydrolyse qui – en accord avec Sutton /1/ –

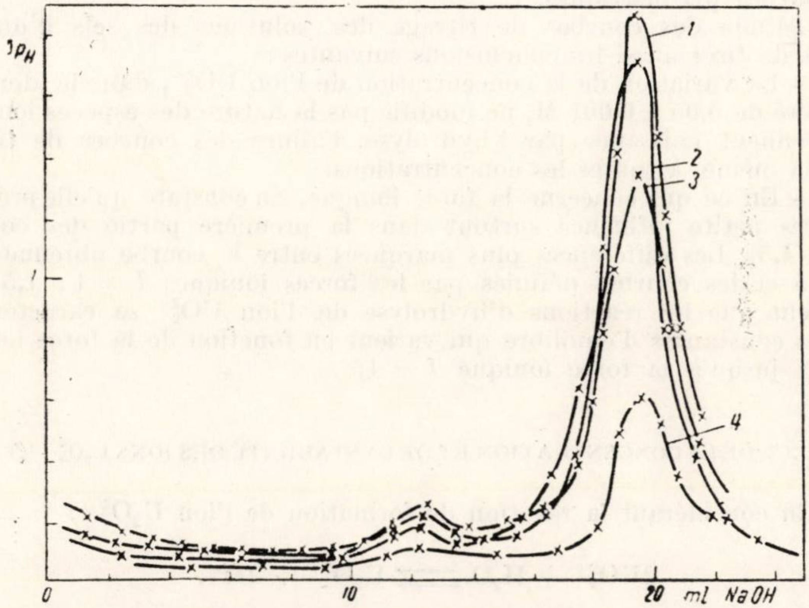

Fig. 6. — Courbes différentielles de titrage pH-métrique des solutions de perchlorate d'uranyle de concentration variée : $C = 0{,}05$ M (*1*) ; $C = 0{,}02$ M (*2*) ; $C = 0{,}01$ M (*3*) ; $C = 0{,}001$ M (*4*).

— peut être représenté par la chaîne réactionnelle :

$$2UO_2^{2+} + H_2O \rightleftarrows U_2O_5^{2+} + 2H^+ \qquad \text{(a)}$$

$$U_2O_5^{2+} + UO_2^{2+} + H_2O \rightleftarrows U_3O_8^{2+} + 2H^+ \qquad \text{(b)}$$

$$U_3O_8^{2+} + H_2O \rightleftarrows U_3O_8(OH)^+ + H^+ \qquad \text{(c)}$$

$$U_3O_8(OH)^+ + H_2O \rightleftarrows U_3O_8(OH)_2 + H^+ \qquad \text{(d)}$$

$$U_3O_8(OH)_2 + H_2O \rightleftarrows U_3O_8(OH)_3^- + H^+ \qquad \text{(e)}$$

$$U_3O_8(OH)_3^- + H_2O \rightleftarrows U_3O_8(OH)_4^{2-} + H^+ \text{ etc.} \qquad \text{(f)}$$

Les réactions (a) et (b) qui conduisent à la formation des ions polymères caractérisés par des ponts d'oxygène ($U_2O_5^{2+}$ et $U_3O_8^{2+}$) sont représentées par la première partie ascendante de la courbe de titrage.

La réaction (c), d'addition d'un ion OH^- à l'ion $U_3O_8^{2+}$, est marquée par un premier saut du pH. La formation de l'anion $U_3O_8(OH)_3^-$ (la réaction e) est indiquée par la seconde inflexion de la courbe de titrage située à des valeurs du pH > 6. On peut considérer que l'addition des ions OH^- continue et que dans le système il se forme des anions du type $U_3O_8(OH)_4^{2-}$... ..., etc., processus qui ne peut être défini et limité par l'analyse directe des courbes pH-métriques.

L'étude des courbes de titrage des solutions des sels d'uranyle permet de tirer aussi les conclusions suivantes :

— La variation de la concentration de l'ion UO_2^{2+}, dans le domaine considéré de 0,05 à 0,001 M, ne modifie pas la nature des espèces ioniques qui prennent naissance par l'hydrolyse, l'allure des courbes de titrage étant la même, à toutes les concentrations.

— En ce qui concerne la force ionique, on constate qu'elle présente une très petite influence surtout dans la première partie des courbes (pH $> 4{,}5$). Les différences plus marquées entre la courbe obtenue pour $I = 0{,}5$ et les courbes définies par les forces ioniques $I = 1$; 1,5 et 2 indiquent que les réactions d'hydrolyse de l'ion UO_2^{2+} se caractérisent par des constantes d'équilibre qui varient en fonction de la force ionique surtout jusqu'à la force ionique $I = 1$.

2.2. CALCUL DE LA CONCENTRATION ET DE LA STABILITÉ DES IONS $U_2O_5^{2+}$ ET $U_3O_8^{2+}$

En considérant la réaction de formation de l'ion $U_2O_5^{2+}$:

$$2UO_2^{2+} + H_2O \rightleftarrows U_2O_5^{2+} + 2H^+,$$

si q = ml solution de NaOH de concentration c mole/l, ajoutés, par titrage, à p = ml solution de perchlorate d'uranyle de concentration m (mole/l) et $u = UO_2^{2+}$; $v = U_2O_5^{2+}$; $h = H^+$; $K_w/h = OH^-$ — les concentrations des différentes espèces ioniques qui participent à la réaction, on peut écrire les relations (1) (qui exprime le bilan de l'uranium) et (2) qui exprime l'électroneutralité de la solution) :

$$u + 2v = pm/p + q \tag{1}$$

$$2u + 2v + h + qc/p + q = \frac{2pm}{p+q} + \frac{K_w}{h} \tag{2}$$

dans lesquelles :

$\dfrac{qc}{p+q}$ représente la concentration de l'ion Na^+

et

$\dfrac{2\,pm}{p+q}$ — la concentration de l'ion ClO_4^-.

En résolvant les équations (1) et (2) (*p*, *m*, *q* et *c* sont connus des données initiales et *h* est déterminé par calcul à l'aide des données pH-métriques), on obtient $u = UO_2^{2+}$ et $v = U_2O_5^{2+}$, en équilibre au pH considéré.

En connaissant *u* et *v*, la constante de stabilité de l'ion $U_2O_5^{2+}$ se détermine à l'aide de la relation :

$$K_1 = \frac{vh^2}{u^2} \tag{3}$$

Dans ce travail on a étudié la formation de l'ion $U_2O_5^{2+}$ dans des solutions de perchlorate d'uranyle de différentes concentrations et forces ioniques.

On a effectué des calculs pour un domaine de pH, dont la limite supérieure ($\simeq 4 - 4{,}5$) a été déterminée par le commencement de la précipitation.

Les résultats obtenus en utilisant la relation (3) qui considère que, dans un certain domaine de pH, coexistent dans la solution seulement les ions UO_2^{2+} et $U_2O_5^{2+}$, sont présentés dans les tableaux 1–16. (Les études ont été effectuées sur des solutions de différentes concentrations et forces ioniques ; les conditions exactes de travail sont mentionnées dans chaque tableau).

Tel qu'on le voit dans les tableaux 1–16 et les figures 7 et 8, la constante K_1 présente, dans le domaine de pH dans lequel on peut considérer que dans la solution coexistent seulement les ions UO_2^{2+} et $U_2O_5^{2+}$, une valeur moyenne d'environ 1.10^{-6}, en accord avec les données de la littérature. [1-3]

À un certain pH, situé dans le domaine de 3,6 à 4 (la valeur exacte dépend des paramètres qui caractérisent le milieu de réaction) on constate une augmentation brusque de la valeur déterminée pour la constante K_1, ce qui prouve que, à partir de cette valeur de pH, les espèces ioniques qui coexistent dans la solution près de l'ion UO_2^{2+} et $U_2O_5^{2+}$ se forment dans des quantités qui ne peuvent plus être négligées. (Pour ce domaine de pH, l'équation (3) ne conduit plus à des valeurs correctes.)

Le pH qui correspond à cette augmentation brusque de la valeur de la constante K_1 limite le domaine dans lequel on peut considérer que, dans la solution, il se forme, comme produits d'hydrolyse de l'ion U^{6+}, seulement les ions UO_2^{2+} et $U_2O_5^{2+}$.

En ce qui concerne la formation et la stabilité des ions $U_3O_8^{2+}$, en considérant la réaction :

$$U_2O_5^{2+} + UO_2^{2+} + H_2O \rightleftharpoons U_3O_8^{2+} + 2H^+,$$

si on applique le principe de l'électroneutralité, on peut écrire la relation :

$$2u + 2v + 2w + h = \frac{2\,pm - qc}{(p+q)} \tag{4}$$

dans laquelle w, u, v et h représentent les concentrations (mole/l) des ions $U_3O_8^{2+}$ (w), UO_2^{2+}(u), $U_2O_5^{2+}$ (v) et H^+ (h). (Les autres symboles p, m, q et c ont les mêmes significations que pour la relation (3).)

En résolvant l'équation (4) on obtient $w = U_3O_8^{2+}$ en équilibre, dans les conditions de pH, concentration et force ionique considérées.

En connaissant $u = UO_2^{2+}$, $v = U_2O_5^{2+}$ et $w = U_3O_8^{2+}$, la constante de stabilité de l'ion $U_3O_8^{2+}$ peut être calculée à l'aide de la relation :

$$K_2 = \frac{wh^2}{uv} \tag{5}$$

Dans ce travail on a étudié la formation de l'ion $U_3O_8^{2+}$ dans des solutions de perchlorate d'uranyle de différentes concentrations et forces ioniques. (Les résultats sont représentés dans les figures 9–10.)

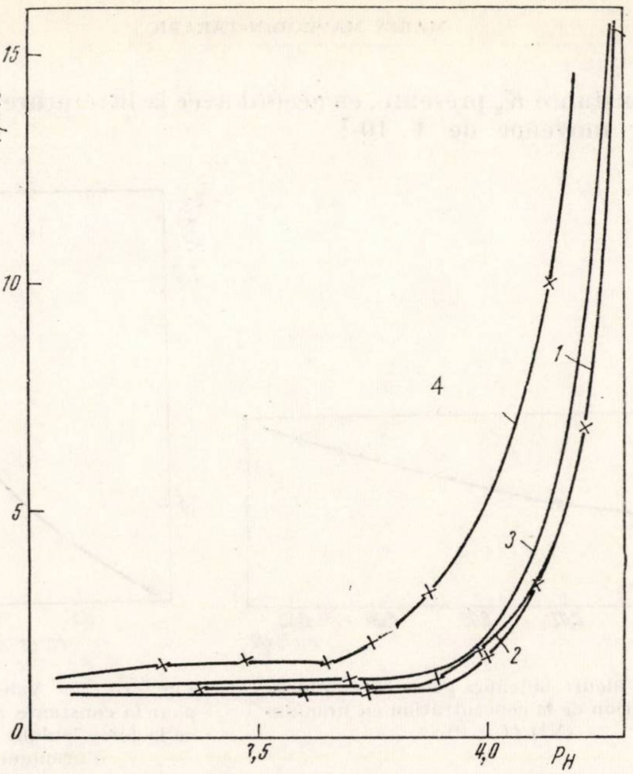

Fig. 7. — Valeurs obtenues pour la constante K_1, en travaillant sur des solutions de perchlorate d'uranyle caractérisées par concentration constante (0,02 M) et forces ioniques variées :
$I = 0,5$ (*1*) ; $I = 1$(*2*) ; $I = 1,5$ (*3*) et $I = 2$ (*4*).

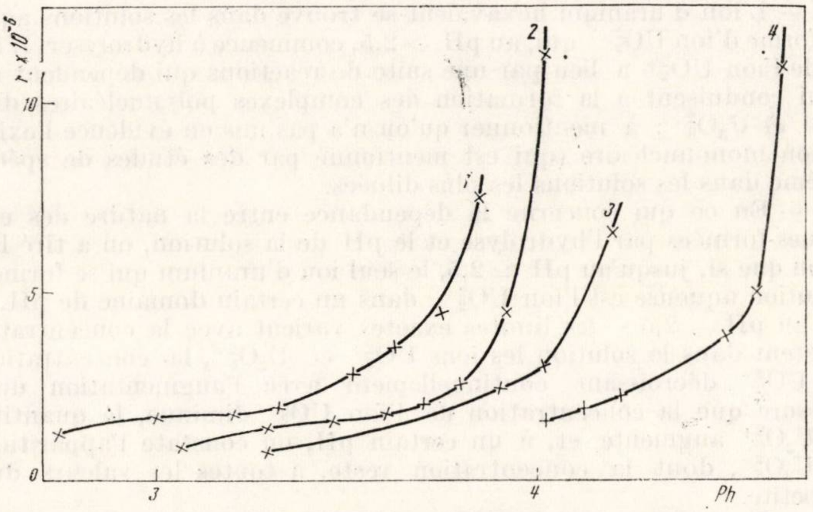

Fig. 8. — Valeurs obtenues pour la constante K_1, en travaillant sur des solutions de perchlorate d'uranyle caractérisées par force ionique constante ($I = 1$) et concentrations variées :
$C = 0,05$M(*1*) ; $C = 0,02$ M (*2*) ; $C = 0,01$ M(*3*) et $C = 0,001$ M (*4*).

La constante K_2 présente, en accord avec la littérature de spécialité, [1] une valeur moyenne de $1 . 10^{-7}$.

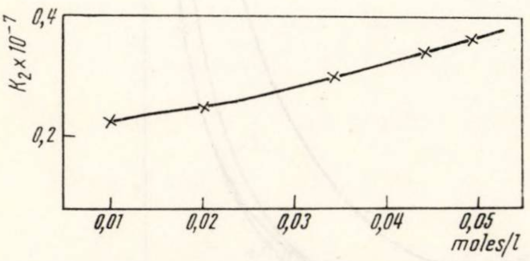

Fig. 9. — Valeurs obtenues pour la constante K_2, en fonction de la concentration en uranium (VI) ($I = 0$).

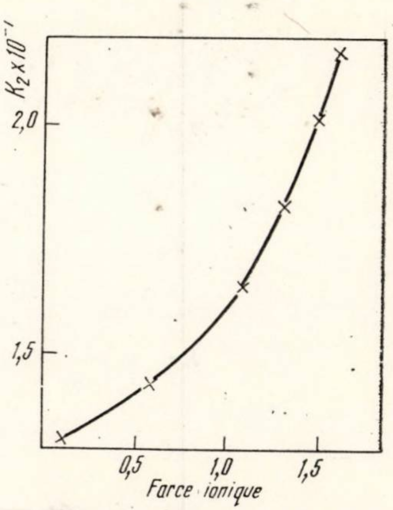

Fig. 10. — Valeurs obtenues pour la constante K_2, en fonction de la force ionique de la solution d'uranium (VI).

CONCLUSIONS

— L'ion d'uranium hexavalent se trouve dans les solutions aqueuses sous forme d'ion UO_2^{2+} qui, au pH $> 2{,}5$, commence à hydrolyser. L'hydrolyse de l'ion UO_2^{2+} a lieu par une suite de réactions qui dépendent du pH et qui conduisent à la formation des complexes polynucléaires, du type $U_2O_5^{2+}$ et $U_3O_8^{2+}$; à mentionner qu'on n'a pas mis en évidence l'existence de l'ion mononucléaire (qui est mentionné par des études de spécialité) ni même dans les solutions les plus diluées.

— En ce qui concerne la dépendance entre la nature des espèces ioniques formées par l'hydrolyse et le pH de la solution, on a tiré la conclusion que si, jusqu'au pH $\simeq 2{,}5$, le seul ion d'uranium qui se forme dans la solution aqueuse est l'ion UO_2^{2+}, dans un certain domaine de pH, supérieur au pH $= 2{,}5$ — les limites exactes varient avec la concentration — coexistent dans la solution les ions UO_2^{2+} et $U_2O_5^{2+}$, la concentration des ions UO_2^{2+} décroissant continuellement avec l'augmentation du pH. À mesure que la concentration de l'ion UO_2^{2+} diminue, la quantité des ions $U_2O_5^{2+}$ augmente et, à un certain pH, on constate l'apparition des ions $U_3O_8^{2+}$, dont la concentration reste, à toutes les valeurs du pH, très petite.

— La stabilité des ions $U_2O_5^{2+}$ et $U_3O_8^{2+}$ se caractérise par les valeurs moyennes des constantes d'équilibre, $K_1 = 1.10^{-6}$ et $K_2 = 1.10^{-7}$ et augmente avec la force ionique de la solution.

Received June 2, 1972

Molecular orbital calculations in the framework of Pariser-Parr (P—P) theory have been applied to some ground state properties and to UV spectra of the four isomeric thienylfurans. The good agreement is obtained with the experiment for the first $\pi - \pi^*$ electronic transition. No conclusion could be reached about preferred conformational arrangements on the grounds of only the P—P calculations for *syn* and *anti* forms, because the results of calculations for both forms agree rather closely with the experimental values. Extended Hückel MO results indicate that the 2, 3′- and 2, 3′-thienylfurans have planar *syn* conformation, while 3, 3′-thienylfuran planar *anti* conformation. For 3, 2′-isomer there is no distinction between the two planar forms. Bond length calculations predicted a very long bond between the heterocycles, which have preserved to a great extent the geometries of individual furan and thiophene ring systems.

The four isomeric thienylfurans : 2-(2′-thienyl)furan (*1*), 3-(2′-thienyl) furan (*2*), 2-(3′-thienyl) furan (*3*), and 3-(3′-thienyl) furan (*4*), have recently been synthesized.[1] These molecules belong to the class of the isomeric compounds consisting of two heterocyclic five-membered rings separated by an essential single bond (~ 1.46 Å) and are of current interest.[1–15]

Some molecules of this class of compounds: bithienyls (2,2′-(*5*), 2,3′-(*6*), and 3,3′-(*7*)) and bifuryls (2,2′-(*8*), 2,3′(-*9*), and 3,3′-(*10*)) have been previously reported and their chemical and spectral properties investigated.[2-9] The skeletal structures of isomeric thienylfurans (*1—4*), bithienyls (*5—7*), and bifuryls (*8—10*) in *anti* forms are shown in Fig. 1.

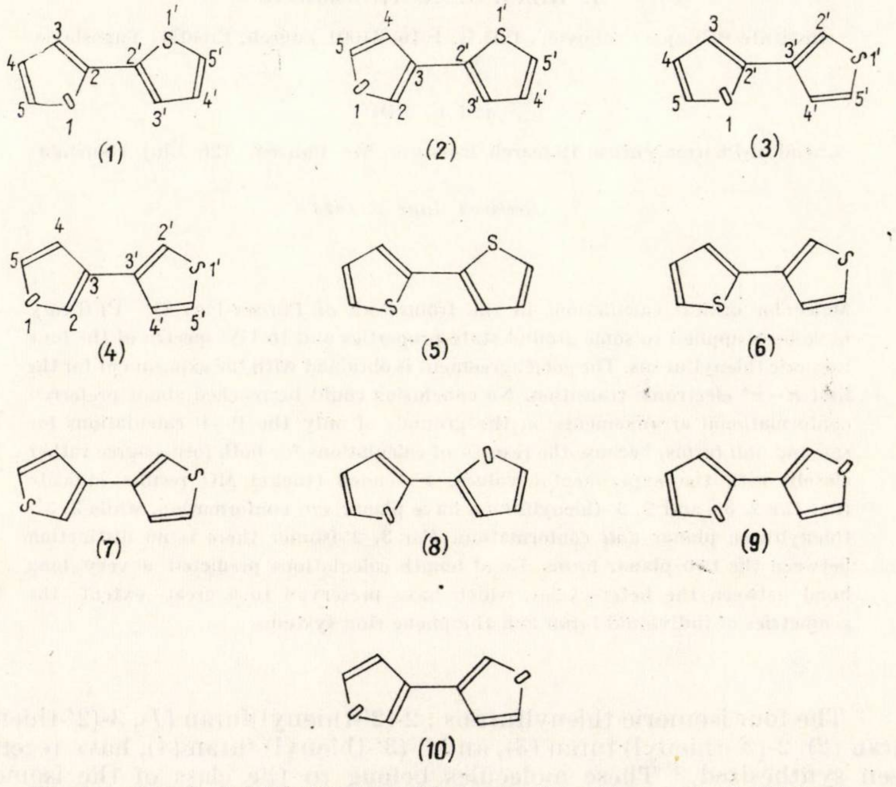

Fig. 1. — Atomic skeletal structure of isomeric thienylfurans (*1—4*), bithienyls (*5—7*), and bifuryls (*8—10*) in *anti* form.

We have studied thienylfurans (*1—4*) using the semi-empirical method of Pariser and Parr[16] (P—P) in order to interpret their electronic spectra. The P—P method has been shown to be a very reliable method for studying the electronic spectra of various kinds of hydrocarbons and heteroconjugated systems.[17,18] Since the formalism of the P—P method has been presented rather extensively in recent monographs,[17-19] need not to be repeated here. The standard set of parameters for C, O, and S is used. The values of the one-center electron repulsion integrals and one-electron core resonance integrals are given in Table 1. The two-center electron repulsion integrals have been determined in the Mataga-Nishimoto manner.[20]

In the present calculations sulphur is considered without *d*-orbital participation. Reasons for this are several: the experience of various authors in their studies,[21−24] our recent work on the ground and excited states of σ-bivalent sulphur compounds.[12,25−27] Finally, some recent *ab initio* SCF MO calculations on very small molecules (H_2S)[28] or ions (α-sulphinyl carbanion)[29] have shown that the 3d-AO′ s of σ-bivalent sulphur are too high in energy[30,31] to have much importance in bonding.

All calculations have been carried out with a FORTRAN program coded for a CEA 90−40 computer.

RESULTS AND DISCUSSIONS

Thienylfurans consist of the two heterocyclic ring systems (furan and thiophene) separated by one essential carbon (sp^2)-carbon (sp^2) single bond. These compounds are expected to appear in planar *syn* or planar *anti* (or twisted) forms. There are no experimental evidences concerning conformations of thienylfurans available as yet. However, there are some experimental studies reported for related systems, e.g.: 2,2'-bithienyl (*5*) and 3,3'-bithienyl (*7*). The electron diffraction studies of 2,2'-bithienyl vapour [14] show that the thiophene ring systems in this molecule are twisted in an *anti* form and have practically the same dimensions as thiophene itself. [32] It has also been found that the length of the bond joining the two thiophene rings ($C_2-C'_2$) is 1.48 Å. This bond is only a little (0.032 Å) shorter than the single bond (1.512 Å) between the two sp^2-hybridized carbon atoms. This implies the very small π-interaction between the two rings. On the other hand, the x-ray studies [15] on 2,2'-bithienyl, 2,3'-bithienyl, and 3,3'-bithienyl have shown these molecules planar in *anti* forms. The interring distance is again found to be rather long, e.g.: 1.49 Å (*5*), 1.46 Å (*6*), and 1.48 Å (*7*), respectively. Some theoretical studies[10-14] on bond lengths in bithienyls agreed with these findings. Similarly, the theoretical studies by Skancke [15] predicted the *anti* form of 3,3'-bithienyl to be more stable than *syn* form, and the angle of twist 30° and 150° for the two forms relative to *syn* form. However, there was no such a clear distinction between the planar and twisted forms of 2,2'-bithienyl; the planar form being somewhat less favourable than non-planar one.

In the light of these structural possibilities in bithienyls we have carried out P—P calculations for the planar *syn* and planar *anti* forms of the four isomeric thienylfurans. Some trial calculations have been performed at earlier stages of this work with the assumed starting interring distance of 1.40 Å, but it converged to the final value of 1.46 Å. Calculated bond orders were converted to bond lengths using the expression of Coulson and Golebiewski. [33] As a result of these trial calculations the value of 1.46 Å as the interring distance was adopted in all present calculations. In our earlier work [13] on the electronic structure of bithienyls and bifuryls we have found the same thing: interring bond orders always converged to such values of bond orders which gave, through the Coulson-Golebiewski bond order-bond length relationship, the bond lengths of 1.46—1.48 Å.

The calculated singlet-singlet transition energies (ΔE, eV) and oscillator strengths of the isomeric thienylfurans for both models considered (*syn*: 1.46 Å and *anti*: 1.46 Å) are reported in Table 2. The electronic transition energies and oscillator strengths have been calculated by a limited configuration interaction (LCI) procedure. The experimental data (ΔE, eV and log ε) are also given in Table 2.

We attributed the calculated values: (*1*) = 4.02 (4.01), (*2*) = = 4.22 (4.20), (*3*) = 4.48 (4.49) and (*4*) = 4.64 (4.64) to the first $\pi - \pi^*$ transition (all results in eV values; the results for planar *syn* conformations are reported in brackets). The corresponding experimental values are: (*1*) = 4.19, (*2*) = 4.54, and (*3*) = 4.44 (all results in eV values). There is no low lying $\pi - \pi^*$ band reported in 3-(3'-thienyl)furan. The difference between the calculated and experimental values is of the order of 0.2 Å; the calculated values being always lower. The second $\pi - \pi^*$ transition is always less intense. The calculated values: (*1*) = 5.27 (5.27), (*2*) = 5.37

* Experimental data from Ref. 1, Solvent : (96%) ethanol.

(5.37), (*3*) = 5.03 (5.00) and (*4*) = 5.13 (5.13) are attributed to the second $\pi - \pi^*$ transition (all values in eV). The corresponding experimental values are: (*1*) = 5.39, (*3*) = 5.44, and (*4*) = 5.12 (all values in eV). There is no second $\pi - \pi^*$ transition reported in 3-(2′-thienyl) furan. Agreement between the experiment and calculation is again reasonably good, if we accept the assignement made; the average difference between the calculated and experimental values being 0.1 — 0.4eV. Examination of the calculated results shows no difference between the two possible conformational forms. Calculated values for both models: planar *syn* and planar *anti*, are in similar agreement with the experiment. To elaborate this further we have also carried out P—P calculations for planar *syn* and planar *anti* forms of bithienyls and bifuryls with the interring distance of 1.46 Å. The plots of the calculated lower $\pi - \pi^*$ transition energies (ΔE) of thienylfurans, bithienyls and bifuryls (see for these results Table 3) for both possible planar conformations vs. experimental values [1] are shown in Figs. 2 and 3. The agreement with experiment in both cases is almost identical. The points lie reasonably close to a straight line, the correlation coefficients being 0.972 (0.970) and the standard deviation 0.0508 eV (0.0513 eV). Results for planar *syn* forms are given in brackets. The slopes of the least-squares lines (0.915 and 0.898) are close to the theoretical unit value. Apparently the spectral data are not sufficient enough to predict the most preferred conformation in these systems. The excitation energies in these molecules, which consist of two conjugated subsystems joined by one single bond, do not depend on the molecule as a whole, but on the individual subsystems. [34] These were analysed for bithienyls by Wachters and Davies [34] using the local energy method of Longuet-Higgins and Murrell.[35] Wachters and Davies found hardly any difference in transition energies of the two forms, but the corresponding oscillator strengths did differ in the case of 3,3′-bithienyl.

It is obvious that in order to elucidate this question some other theoretical approach must be used. The Extended Hückel Theory (EHT) may be more fruitful in this respect, because there are some clear indications that EHT is a suitable semi-empirical MO method [36-38] for predicting the preferred conformations. EHT theory was applied to the problem of the preferred conformations of isomeric thienylfurans.[39] The preliminary

EHT results show that in 2-(2′-thienyl) furan and 2-(3′-thienyl) furan the planar *syn* form is more stable, while in 3-(3′-thienyl) furan the planar *anti* is more stable. In the case of 3-(2′-thienyl) furan there is no clear distinction obtained between either of these forms. Besides, no tendency to deviate from planarity is shown by any of these systems.

Bond orders are reported in Table 4. The interring bond orders were converted to the corresponding bond lengths using two different

bond order-bond length relations[11,33] :

$$L_{CC} = 1.532 - \frac{0.242\ p_{CC}}{1 + 0.420\ p_{CC}}\ (\text{Å}) \qquad (\text{I})^{11}$$

and

$$L_{CC} = 1.517 - 0.180 \qquad (\text{Å}) \qquad (\text{II})^{33}$$

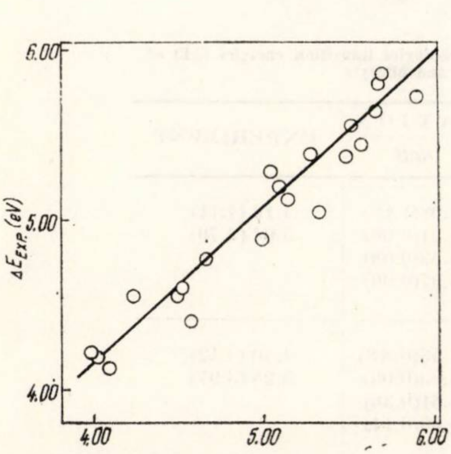

Fig. 2. — The plot of experimental vs. calculated lower $\pi-\pi^*$ transition energies for *anti* forms.

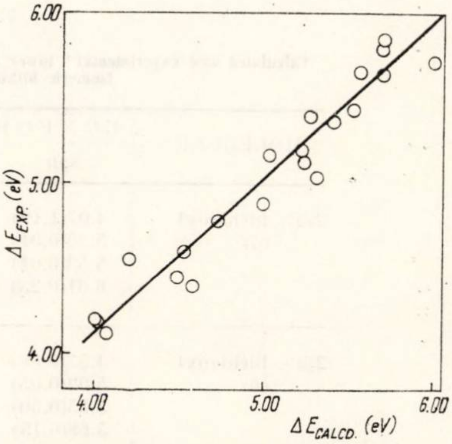

Fig. 3. — The plot of experimental vs. calculated lower $\pi-\pi^*$ transition energies for *syn* forms.

The following calculated values are obtained for the interring distance :

Molecule	Bond	Predicted interring distance (in Å)	
		(I)	(II)
(1)	2—2′	1.45	1.45
(2)	3—2′	1.46	1.46
(3)	2—3′	1.46	1.45
(4)	3—3′	1.46	1.46

These results suggest that the experimental interring distances in thienylfurans should be foundat about 1.46 Å.

The inspection of the other bond orders shows that the geometries of ring systems are very alike to those of the individual molecules making up the isomeric thienylfurans, e.g. : thiophene and furan.

We report in Table 5 calculated molecular geometry for 2-(2′-thienyl) furan as an example and experimental geometries of thiophene[32] and

furan. [40] The following linear relationships for converting the bond orders to CS [11] and CO [41] bond lengths have been used :

$$L_{CS} = 1.829 - 0.262\ p_{CS}$$

$$L_{CO} = 1.437 - 0.165\ p_{CO}$$

It is clearly seen that both ring systems have geometries very similar to those of furan and thiophene; the overall difference between two sets of values being only 0.007 Å.

Table 5

Calculated bond lengths in 2-(2′-thienyl) furan (1)

[41] Adapted from G. Häfelinger, *Chem. Ber.*, **103**, 2922 (1970).

Charge densities are reported in Table 6. Oxygen and sulphur each contribute two electrons to the π system, and the charge densities on oxygen and sulphur acquire positive charges in every case. The acquired positive charge is smaller on oxygen than sulphur, due to a larger value of the ionization potential for oxygen. In other words, the π electrons of oxygen are more firmly bound than those on sulphur. The charge densities on carbon atoms are pretty evenly distributed and carbon atoms acquire negative charge in every case.

ELECTRONIC STRUCTURE AND TRANSITIONS OF 1, 2, 3-TRIMETHOXYACRIDINE

M. VLASSA, MARIA IONESCU

Institute of Chemistry, Str. Donath 59–65, Cluj, Romania

and

J. FABIAN

Department of Chemistry, Technical University Dresden, The German Democratic Republic

Received May 12, 1972

The reactivity indices (π-electron density, π-bond order, free valence index, superdelocalizability index), the bond lengths and the electronic transition (singlet-singlet, singlet-triplet and triplet-triplet) of 1,2,3-trimethoxyacridine (I) and of parent compound acridine, were computed by a SCF–LCI* method. The calculated electronic energies are in good agreement with experimental data.

INTRODUCTION

In connection with current investigation on 1, 2, 3-trimethoxyacridine derivatives [1,2] we calculated the π-electronic transitions and the reactivity of 1, 2, 3-trimethoxyacridine (I). For comparison, the π-electronic structure and electronic transitions of the unsubstituted compound, acridine, **were also computed.

A better knowledge of the physical properties might be important in order to understand the chemical and photochemical behaviour of compound I.

The reactivity is discussed by means of π-reactivity indices. The limits of such a consideration are well known. Among the excited states only the states resulting from $\pi - \pi^*$ transitions were calculated.

METHOD OF CALCULATION

The calculations were performed by the SCF–LCI(PPP) method. For computing the transition energies, the interactions between the monoexcited configurations were set up from HMO and SCF functions. Those configurations which use electronic transitions between the four highest occupied and the four lowest virtual molecular orbitals were selected.

---

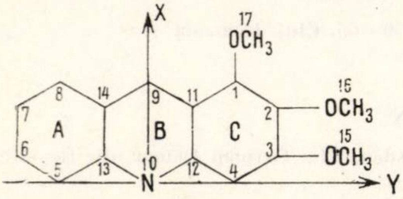
* LCI = Limited configuration interaction.

** The following abbreviations were used in the text : A for acridine, and TMA for 1, 2, 3-trimethoxyacridine.

[1] M. Ionescu and M. Vlassa, *Rev. Roumaine Chim.*, **16**, 743 (1971).

[2] M. Ionescu, M. Vlassa and I. Goia, *J. prakt. Chem.*, **314**, 441 (1972).

The PPP calculations were performed by following the Mataga-Nishimoto procedure [3] for two center repulsion integrals. This approximation is successfully used in the calculation of the electronic distribution, ionization potential and spectral data of heterocyclic compounds.



I

Fig. 1. — Coordinate system used for 1,2, 3,-trimethoxyacridine (I).

The π-electronic system of the 1, 2, 3-trimethoxyacridine molecule consists of a number of 20 π-electrons delocalized over 17 centers. The molecule is assumed to be planar (C_s symmetry group) with an idealized bond distance of $r_{CC} = r_{CN} = r_{CO} = 1.40$ Å. The coordinate system used is given in figure 1.

For resonance integrals we chose the following value: $\beta_{CC} = \beta_{CN} = \beta_{CO} = -2.38$ eV (PPP/1). For comparison, with the data which will be published in a forthcoming paper on the N-oxides, an enlarged value for β_{CN}($\beta_{CN} = -2.636$ eV) was used in a second computation (PPP/2). This value was derived from π-bond order p_{CN} of acridine-N-oxide given by Mantsch and co-workers using the following linear β/p relations[4]:

$$\beta_{CC} = -0.51\,p - 2.04 \text{ eV} \quad (1)$$

$$\beta_{CN} = -0.53\,p - 2.34 \text{ eV} \quad (2)$$

The one center repulsion integrals $\gamma_{\mu\mu}$ and the core integrals U_μ were taken from the literature [5,6]: $\gamma_{CC} = 8.25$ eV, $\gamma_{NN} = 9.50$ eV, $\gamma_{OO} = 12.60$ eV; $U_C = 8.72$ eV, $U_N = 11.72$ eV and $U_O = 20.72$ eV.

An initial set of orthogonalized eigenvectors obtained by a Hückel approximation ($h_{\dot{N}} = 0.5$, $h_{\ddot{O}} = 2$; $k_{CC} = k_{CO} = 1$ and $k_{CN} = 1.1075$) were taken to construct the self-consistent molecular orbitals.

The molecular orbitals obtained from simple Hückel and PPP's procedures, respectively, were used then as a basis for a configuration interaction treatment (HMO—LCI with the same parameters as for PPP/2).

---

[3] K. Nishimoto and N. Mataga, *Z. phys. Chem.* (Frankfurt), **12**, 335 (1957).

[4] K. Nishimoto and L. Forster, *Theor. Chim. Acta*, **5**, 155 (1966); *Chem. Phys.*, **71**, 409 (1967).

[5] H. H. Mantsch, W. Seiffert and V. Zanker, *Rev. Roumaine Chim.*, **14**, 125 (1969).

[6] F. Dörr, C. Hohlneicher and S. Schneider, *Ber. Bunsengesellscaft Phys. Chem.* **70**, 803 (1966).

The π-electronic system of the acridine molecule consists of a number of 14 π-electrons, delocalized over 14 centers. The molecule is also planar (C_{2V} symmetry group), the bond distances r_{CC} and r_{CN} were both taken as 1.40 Å. The same coordinate system was considered as for 1, 2, 3-trimethoxyacridine (I). The electronic structure of acridine was calculated only with parameters used in the PPP/1 computation.

The input data used in these calculations are shown in Table 1.

Table 1

The input data for acridine (1 – 14) and for 1, 2, 3-trimethoxyacridine (1 – 17)

Center	Coordinate		Ionization potential eV	Electron affinity eV	Number of contributing electrons
	X	Y			
1	2.420	2.800	8.72	0.47	1

8	2.420	2.800	8.72	0.47	1
9	0.000	2.800	8.72	0.47	1
10	0.000	0.000	11.72	2.22	1
11	1.210	2.100	8.72	0.47	1
12	1.210	0.700	8.72	0.47	1
13	1.210	0.700	8.72	0.47	1
14	1.210	2.100	8.72	0.47	1
15	4.840	0.000	20.72	12.00	2
16	4.840	2.800	20.72	12.00	2
17	2.420	4.200	20.72	12.00	2

The CC, CO and CN bond lengths were estimated by two methods :

a) using the relations given by Nishimoto and Forster, [4] which assume that the differences between the double bond distances are all 1.80 Å :

$$r_{CC} = 1.517 - 0.180\ p \text{ Å} \quad (3)$$

$$r_{CN} = 1.451 - 0.180\ p \text{ Å} \quad (4)$$

$$r_{CO} = 1.410 - 0.180\ p \text{ Å} \quad (5)$$

b) using Jenkins' relation [7] :

$$d = \frac{1}{A + B(1 + p)} \text{ Å} \qquad (6)$$

where the constants A/B are 0.2868/0.1334 for CC bonds and 0.316/0.144 for CN bonds. A good agreement was observed for the values of the CC and CN bond lengths calculated by these two procedures.

---

[7] H. O. Jenkins, *J. Amer. Chem. Soc.*, **77**, 3168 (1955).

The calculations were carried out on an Elliot 503 b computer with an autocode program.

RESULTS AND DISCUSSION

The bond order (p_μ), the π-electronic density (q_μ), the bond length ($r_{\mu\mu}$), the free valence index (F_μ), as well as the superdelocalizability index (S_μ) were obtained for 1, 2, 3-trimethoxyacridine (I) and for acridine starting from these coefficients and orbital energies.[8] The results of our calculations are shown in Tables 2–6.

Table 2

* Superdelocalizability index was calculated using only HMO coefficients and energy.

From the data in the Table 2 it can be seen how the presence of the methoxy groups (with + *M* effect) changes the electron density distribution relatively to the parent compound, acridine. The electron density of the nitrogen atom increases, the 1, 2, 3-trimethoxyacridine molecule being more basic than the parent compound (see tables 2 and 3).

For 1, 2, 3-trimethoxyacridine (I) we could verify the rule observed by Tiutulkov and co-workers,[9] namely that the basicity of the excited singlet state (S_1) is greater and that of the excited triplet state (T_1) is lower than the one of the ground state (see Table 2). For acridine our calculations pointed out that the excited singlet state (S_1) has a lower basicity than the ground state ($q_{\mathrm{N}}^{\mathrm{O}} = 1.299$ and $q_{\mathrm{N}}^{S_1} = 1.275$; Tiutulkov[9] found $q_{\mathrm{N}}^{\mathrm{O}} = 1.118$ and $q_{\mathrm{N}}^{S_1} = 1.135$), however the excited triplet state (T_1) has a lower basicity than the ground state.

The electron density of the 1, 2, 3-trimethoxyacridine molecule is greater than of the parent compound acridine (see Table 2), especially in the *C* and *B* rings (see Fig. 1), with the exception of the C_3 ring atom. The influence of the three methoxy groups in the vicinal positions 1, 2 and 3 lowers the electron density at C_3 and increases it mostly at $C_4(q_4 = +0.089)$. Since the electron density is increased in 1, 2, 3-trimethoxyacridine (I), the electrophilic substitution takes place easier than in the case of acridine (especially at C_4, $F_A = 0.458$ and $F_{\mathrm{TMA}} = 0.601$).

12	0.106	0.128	0.142	0.282	0.138	0.172
13	0.106	0.128	0.142	0.282	0.138	0.172
14	0.106	0.109	0.121	0.235	0.121	0.148

The nucleophilic substitution which is characteristic for the C_9 position, has the same probability for both molecules ($F_A = 0.516$ and $F_{TMA} = 0.509$).

By inspecting the reactivity indices for the carbon atoms of compound I (see Table 3), the tendency to electrophilic substitution decreases in the order : $4 > 5 > 7$ (for acridine this order is $2 = 7 > 4 = 5$ [10,11] identical with our results, see table 4).

As with acridine, the position 9 remains the most probable center for nucleophilic and radicalic substitution ; the reactivity of the carbon atoms towards nucleophilic substitution is $9 > 8 > 6$.

The electron density of I has the same characteristics for the PPP/2 computation as for the simple Hückel method (Tables 3 and 5).

As shown by the free valence values the reactivity is increased in the excited singlet and triplet states, while the bond lengths are not changed.

The bond lengths calculated for acridine in this work, are in good agreement with the bond lengths of the acridine molecule as determined by x-ray diffraction [12] (see Table 5).

The bond lengths and the bond orders for the ground state and for the excited states (S_1, S_2, T_1 and T_2) of 1, 2, 3-trimethoxyacridine (I) are listed in Table 6.

The computed energies for the singlet-singlet, singlet-triplet and triplet-triplet transitions of acridine and of 1, 2, 3-trimethoxyacridine (I) are summarized in Tables 7—10, along with their transition moments, the direction of the transition moments, the oscillator strengths, the configurational weights as well as the experimental values.

compound, acridine. At shorter wave lengths a very intense transition follows, which in comparison with the corresponding transition of the parent compound experience a hypsochromic shift.

Table 11 shows the dipole moments of acridine and for 1, 2, 3-trimethoxyacridine (I). The calculated value for the S_0 state of acridine is in good agreement with the experimental value.[15] The direction of the calculated dipole moment is 270°0′8″ for acridine (towards the nitrogen atom) and 228°58′40″ for compound I (towards the $N-C_{13}$ bond).

Table 11

Calculated dipole moment for acridine and 1, 2,3-trimethoxyacridine

Compound	State	Dipole moment (D)	Experimental data
1, 2, 3-trimethoxyacridine	S_0	3.884	
	S_1	9.441	
	S_2	6.580	
	T_1	4.850	
	T_2	4.407	
acridine	S_0	1.856	1.940 [15]
	S_1	0.829	
	S_2	1.457	
	T_1	1.159	
	T_2	0.299	

The ability of a molecule to function as donor in a donor-acceptor complex is measured by the ionization potential. The molecular ionization potential and the electron affinity is related to the energy of the highest occupied (HOMO) and lowest virtual orbital energy (LVMO), respectively.[16] When one-center integral is used, the ionization potential equals the amount of HOMO energy :

$$IP = |e_{\mathrm{HOMO}}|$$

and the electron affinity equals the amount of LVMO energy :

$$EA = |e_{\mathrm{LVMO}}|$$

For 1, 2, 3-trimethoxyacridine (I) $IP = 7.22$ eV and $EA = 1.93$ eV (PPP/1). Our calculations give for the ionization potential of acridine the value 7.71 eV (experimental value 7.70 eV[17]). This suggests that 1, 2, 3-trimethoxyacridine (I) has a lower electron affinity relatively to acridine ($2.24_{\mathrm{A}} - 1.93_{\mathrm{TMA}} = 0.31$ eV).

EXPERIMENTAL

The uv spectrum of 1, 2, 3-trimethoxyacridine (I) was recorded in hexane solution ($c = 0.00283$ mg/ml) on a Carl Zeiss Jena SPECORD spectrometer. 1, 2, 3-Trimethoxyacridine was prepared by a method reported in a previous paper.[2]

RELATIONS CONCERNANT LA STRUCTURE ÉLECTRONIQUE ET LA RÉACTIVITÉ DE QUELQUES THIOAMIDES

FELICIA CORNEA *, CORNELIA FULEA * et A. O. FULEA **

* Laboratoire de Chimie organique, Faculté de Chimie, Université de Bucarest
** Laboratoire de Physique-Chimie des macromolécules, Faculté de Chimie, Université de Bucarest

Reçu le 12 fevrier 1972

Pour expliquer la manière dont la structure électronique détermine la réactivité de quelques thioamides, on a appliqué la méthode des orbitales moléculaires en utilisant l'approximation Hückel et la technique ω, pour neuf thioamides. Pour le groupement fonctionnel thioamidique et thioamidique protoné on a pris en considération les structures suivantes : $-C(:S)NH_2$; $-C(:NH)SH$; $-C(:\overset{+}{S}H)NH_2$ et $-C(:\overset{+}{N}H_2)SH$. Dans ce travail on utilise pour la première fois un système complet de paramètre pour ces formes :

$$\alpha_{\dot{S}} = \alpha + 0,5\beta \; ; \; \alpha_{\ddot{S}} = \alpha + \beta \; ; \; \alpha_{\overset{+}{S}} = \alpha + 1,5\,\beta$$

$$\beta_{C=S} = \beta_{C-S} = \beta_{C=\overset{+}{S}} = 0,6\beta \; ; \quad \alpha_{\dot{N}} = \alpha + 0,5\beta$$

$$\alpha_{\ddot{N}} = \alpha + 1,5\beta \; ; \; \alpha_{\overset{+}{N}} = \alpha + 2\beta \; ; \; \beta_{C=N} = \beta$$

$$\beta_{C-N} = 0,8\beta \; ; \; \beta_{C=\overset{+}{N}} = \beta \; ; \; \alpha_{CH_2,CH_3} = \alpha + 2\beta$$

$$\beta_{C-CH_2,\, C-CH_3} = 0,7\beta$$

On a calculé les niveaux d'énergie des électrons π, l'énergie de résonance et les diagrammes de charge, pour les quatre formes des thioamides étudiés. Compte tenu des données obtenues par calculs on estime la tautomérie des thioamides, l'orientation de la substitution électrophile par le groupement thioamidique et la capacité d'accepteur d'hydrogène.

1. INTRODUCTION

Les recherches effectuées dans le domaine des thioamides ont abordé, en particulier, le problème de la synthèse et de la réactivité de ces substances. Des études théoriques ont été aussi effectuées en utilisant la méthode des orbitales moléculaires.

Les méthodes de calcul présentent intérêt au cas où les résultats sont en bonne concordance avec les données obtenues par déterminations expérimentales.

Le modèle de Janssen[1] pour les dérivés thiocarbonyliques a conduit à de bons résultats , tant par la méthode HMO simple, que par la technique ω. On a obtenu une bonne concordance pour les énergies de transition $n \to \pi^*$ et $\pi \to \pi^*$ calculées et déterminées expérimentalement pour quelques dérivés thiocarbonyliques.[1-3] Aussi, autres propriétés, comme la force basique de quelques thioamides et dérivés de la thiourée,[4] les constantes de dissociation de quelques thiocétoacides,[5] déterminées expérimentalement sont-elles en concordance avec les résultats obtenus par calcul.

Sandström[6] a appliqué le modèle de Janssen aux thioacétamide, thiobenzamide et thioacrylamide. Pour les thioacétamide et thiobenzamide on a calculé les niveaux d'énergie, la distribution de la charge, l'ordre de liaison et l'énergie de transition $n \to \pi^*$ et $\pi \to \pi^*$ tant pour l'état fondamental, que pour l'état excité mais pour le thioacrylamide seulement pour l'état fondamental.

La force basique des thioamides a été discutée uniquement pour le thioacétamide, sans prendre en considération l'hyperconjugaison.

Dans la présente note on a effectué une étude théorique pour quelques thioamides qui peuvent être considérés comme premier terme d'une série, en utilisant la méthode HMO simple et la technique ω.

2. LE CHOIX DES PARAMÈTRES

Bien que d'autres paramètres aient été proposés pour les dérivés thiocarbonyliques,[7] le modèle de calcul proposé par Janssen est fréquemment utilisé grâce aux bons résultats obtenus.

Dans ce travail les paramètres de Janssen sont utilisés seulement pour les liaisons $C{=}S$ et $C{-}S$, vu que son travail[1] ne mentionne pas tous les paramètres nécessaires pour décrire les quatre structures possibles du groupement thioamidique. Pour les liaisons $C{=}\overset{+}{S}$, ont été employés les paramètres indiqués par Sandström,[6] tandis que pour les liaisons $C{-}N$, $C{=}N$ et $C{=}\overset{+}{N}$ les paramètres donnés dans plusieurs travaux de Streitwieser[8] et Pullman.[9] Dans la présente note nous avons employé pour la première fois, un système complet de paramètres pour les quatre formes du groupement thioamidique, dont les valeurs sont indiquées dans le tableau 1.

Les groupements $-CH_3$ et $-CH_2-$ ont été assimilés à un hétéroatome qui contribue avec une paire d'électrons au système conjugué. Ce modèle « hétéroatomique » de la hyperconjugaison a donné de bons résultats notamment pour les calculs effectués par la technique ω. [8]

Selon, la technique ω, l'intégrale coulombienne pour un atome r se modifie en fonction de la densité des électrons π à cet atome, q_r et un paramètre sans dimension ω, avec une valeur qui varie entre les limites de 0,33 à 1,8. Dans ce travail $\omega = 1{,}4$ — valeur fréquemment utilisée. Ainsi, l'intégrale coulombienne est définie par la relation :

Tableau 1

Paramètres utilisés pour les calculs dans la présente note

Liaison		h_x	k_x
N	$\mathrm{C-\underset{\vert}{\ddot{N}}-}$	1,5	0,8
	$\mathrm{-C=N-}$	0,5	1
	$\mathrm{C=\underset{\vert}{\overset{+}{N}}-}$	2	1
S	$\mathrm{C-S-}$	1	0,6
	$\mathrm{C=S}$	0,5	0,6
	$\mathrm{C=\overset{+}{S}-}$	1,5	0,6
CH_2, $CH_3=X$		2	0,7

$$\alpha_{r'} = \alpha_r + \omega(n_r - q_r)\beta_{CC}$$

où n_r représente le nombre d'électrons avec lequel l'atome participe à la conjugaison, et qui peut être 1 ou 2.

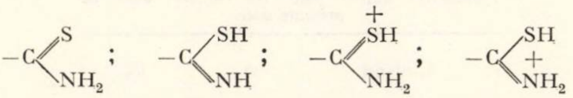
L'intégrale de résonance se modifie en fonction de la longueur de la liaison rs notée R_{rs} et est obtenue par la relation

$$\beta_{rs'} = \beta_{rs} \exp\left[-(R_{rs} - 1{,}397)/0{,}3106\right]$$

Les calculs ont été effectués à l'aide d'une machine de calcul IBM—360, conformément à un programme élaboré par P. Gund de l'Université de Massachusetts.

3. DISCUSSION DES RÉSULTATS

On a effectué des calculs pour les thioamides suivants : thioformamide I, thioacétamide II, phénylthioacétamide III, thiobenzamide IV, thioacrylamide V, cinnamthioamide VI, thio-urée VII, dithiobiuret VIII et dithiomalonamide IX, en considérant pour le groupement thioamidique et thioamide protoné les structures suivantes :



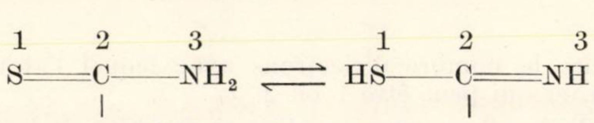
Ces thioamides ont été choisis tels que, sur la base des résultats obtenus, l'on puisse tirer des conclusions sur l'influence des différents radicaux ou groupes d'atomes par l'effet électromère sur la structure électronique du groupement thioamidique.

Compte tenu de toutes les données obtenues par calcul, on apprécie la tautomérie thioamide-isothioamide, l'orientation de la substitution électrophile par le groupement thioamidique lié d'un noyau benzénique et la capacité d'accepteur d'hydrogène des thioamides étudiés.

Pour les thioformamide, phénylthioacétamide, cinnamthioamide, dithiobiuret et dithiomalonthioamide on n'a pas fait jusqu'à présent de calculs par la méthode des orbitales moléculaires.

LA TAUTOMÉRIE THIOAMIDE – ISOTHIOAMIDE

La possibilité d'un équilibre tautomère dans le cas des thioamides est basée, au point de vue théorique, compte tenu de la structure du groupement thioamidique. L'élément structurel essentiel existant dans la molécule d'un thioamide est constitué par le système tricentrique, non saturé, et dans certaines conditions bien déterminées, ont lieu dans ce système des réarrangements par des migrations 1—3.



$$\overset{1}{S}=\underset{|}{\overset{2}{C}}-\overset{3}{NH_2} \rightleftharpoons \overset{1}{HS}-\underset{|}{\overset{2}{C}}=\overset{3}{NH}$$

Cette condition structurale qui conditionne l'apparition de la tautomérie dans la classe des thioamides a conduit à plusieurs études dans le but de mettre en évidence l'existence de cet équilibre, par la détermination de la présence de la forme thioamide ou isothioamide (soit par méthodes chimiques [10] soit par méthodes physiques).

Dans ce sens on donne quelques exemples. Par la comparaison des spectres UV de quelques dérivés convenablement substitués par les spectres des dérivés de référence, Hantzsch[11] montre que, généralement, les thioamides se trouvent sous forme thiocarbonylique. L'étude de 2-mercaptobenzothiazole[12] et de 2-thiopyridone[13] mettent en évidence que la forme thiocarbonylique est prédominante.

---

[10] A. E. A. Werner, *Sci. Proc. Roy. Dublin Soc.*, **22**, 387 (1941), *Chem. Abstr.*, **35**, 54159 (1941).

Les spectres en IR indiquent la forme thionique pour quelques dérivés de la thio-urée,[14] généralement, la forme mésomère $\overset{-}{S}\text{— —}C=\overset{+}{N}H_2$ pour les thioamides,[15] dans une quantité appréciable, et pour les thioamides cycliques[16] et le dithiobiuret,[17] on observe aussi une faible bande qui correspond au groupement —SH, fait qui, dans ce cas, est un argument plaidant pour la présence des deux formes tautomères dans les conditions données.

L'apparition de deux signaux dans le spectre RMN de la thioacétanilide est considérée par certains auteurs comme un argument pour l'existence des formes tautomères.[18] D'autres auteurs[19] considèrent cependant cette constatation comme un argument pour l'existence de deux isomères de type s-*cis* et s-*trans*.

Bien que les deux formes des thioamides (la forme thiocarbonylique et iminothiolique) n'eussent pas été séparées comme on a réussi pour d'autres substances qui présentent le phénomène de la tautomérie, souvent la forme isothioamidique est citée pour expliquer notamment le mécanisme de quelques réactions chimiques des thioamides.

Généralement on considère que l'équilibre est déplacé vers la forme thiocarbonylique.

La constante d'équilibre tautomère K_t[9] est déterminée par la relation :

$$RT \ln K_t = -\Delta G$$

où :

$$\Delta G = \Delta H - T\Delta S$$

Vu que dans le cas de la tautomérie n'a pas lieu un changement du degré d'ordre du système dans les deux formes tautomères, la constante d'équilibre sera déterminée par la variation d'enthalpie du système, fait qui peut être écrit :

$$\Delta H = \Delta H_{\text{conj}} + \Delta H_{H-\text{liaison}}$$

[18] A. J. Speziale et L. R. Smith, *J. Org. Chem.*, **28**, 3492 (1963).

[19] J. D. Rae, *Canad. J. Chem.*, **45**, 1 (1967).

Donc, pour voir quelle est la forme tautomère la plus stable, il faut calculer l'énergie de conjugaison pour les deux formes et la variation de l'énergie quand on passe de la liaison N—H à la liaison —S—H.

$\Delta H_{\text{conjugaison}}$ représente la différence entre les énergies de conjugaison ΔE, caractéristiques des deux formes tautomères :

$$\Delta H_{\text{conj}} = \Delta E_1 - \Delta E_2$$

où déloc = délocalisation

$$\Delta E = E_{\text{déloc}} - E_{\text{loc}}$$

Dans le tableau 2 sont données les valeurs ΔE en unités β pour les quatre formes des thioamides (non protoné et protoné), calculées tant par la méthode HMO simple que par la technique ω.

L'étude des données indiquées dans le tableau 2 révèle que pour la forme thiocarbonylique, ΔE présente, dans tous les cas, des valeurs plus grandes que pour la forme iminothiolique (isothioamidique). Il faut ajouter aussi le fait, que l'énergie de la liaison SH est plus petite avec — 0,7455 β respectivement 12,3 *k*cal/mole que la liaison N—H. [20]

Les valeurs obtenues par la technique ω pour les différences $\Delta E_{\text{thione}} - \Delta E_{\text{thiole}}$ sont plus grandes que celles obtenues par la méthode HMO simple.

L'analyse des données indiquées dans le tableau 2 permet d'observer l'influence de l'introduction d'un noyau benzénique, dans la molécule d'un thioamide sur la valeur ΔE. De cette manière si on compare les valeurs obtenues pour les thioamides II et III et aussi pour les thioamides V et VI, on observe une croissance de la valeur ΔE obtenue tant par la méthode HMO simple que par la technique ω pour la forme thioamidique et isothioamidique.

D'autre part, la comparaison du thioamide III avec IV révèle de petites différences entre les valeurs ΔE, fait qui indique une forte hyperconjugaison du groupement $-CH_2$ avec le reste de la molécule.

Le thioformamide I qui, généralement, peut être considéré comme un groupement thioamidique « pur » présente les plus petites valeurs ΔE, pour les deux formes (par les deux méthodes utilisées), comparativement aux autres thioamides.

Le thioacétamide II et la thio-urée VII peuvent être considérés comme dérivés de I par la substitution de l'atome d'hydrogène par le groupement $-CH_3$ et respectivement NH_2 ; les données du tableau 2 indiquent des valeurs plus grandes de ΔE pour VII que pour II.

Le dithiobiuret VIII et le dithiomalonamide IX peuvent être considérés comme dérivés de la thio-urée VII et du thioacétamide par la substitution d'un atome d'hydrogène par le groupement $CSNH_2$ ce qui conduit à une augmentation de la valeur ΔE si on compare VII et II.

ORIENTATION DE LA SUBSTITUTION ÉLECTROPHILE PAR LE GROUPEMENT CSNH$_2$

Le groupement fonctionnel $-CSNH_2$ par sa structure et l'effet électronique exercé oriente la substitution électrophile sur le noyau benzénique dans la position *méta* (position 3 et 5).

Le calcul de la distribution de la densité de la charge dans la molécule permet d'obtenir des informations sur les positions où peut se produire l'attaque d'un réactant électrophile où nucléophile.

Dans le tableau 3 sont indiquées les densités de la charge pour les thioamides III, IV et VI.

Tableau 3

Valeurs de densité de la charge dans le noyau benzénique

	3,5	1,0005	0,9991	1,0004	0,9992	1,0007	0,9964	1,0007	1,9956
	4	0,9653	0,9975	0,9799	0,9979	0,9484	0,9900	0,9549	0,9877

Dans la molécule du thiobenzamide, où le groupement CSNH$_2$ est lié directement au noyau benzénique, la densité de la charge est maximale dans les positions 3 et 5, comme on pouvait prévoir, compte tenu de la nature du groupement thioamidique.

Dans le cas du cinnaméthioamide, l'influence du groupement thioamidique se transmet par l'intermédiaire du groupement $-CH=CH-$ et en conséquence la densité de la charge est augmentée aussi dans les positions 3 et 5.

L'existence d'un groupement CH$_2$ placé entre le noyau benzénique et le groupement thioamidique dans la molécule du phénylthioacétamide modifie la distribution de la charge. Le groupement CH$_2$ étant un substituent de premier ordre oriente la substitution électrophile dans les positions *ortho* et *para* (ou 2, 4 et 6).

Le diagramme de la distribution de la charge indique dans ce cas que les positions 2, 4 et 6 ont une valeur de la densité électronique plus élevée que les autres positions.

En ce qui concerne les formes tautomères iminothioliques (isothioamidiques), la substitution électrophile est orientée dans les mêmes positions que dans les formes thioniques (thioamidiques).

Vu que la substitution électrophile a lieu d'habitude en milieu acide, nous avons aussi pris en considération les deux formes protonées correspondantes pour les deux formes tautomères.

Dans ce cas, la densité de la charge est aussi augmentée dans les positions 3 et 5 pour les thioamides IV et VI et dans les positions 2, 4 et 6 pour le thioamide III.

LA CAPACITÉ D'ACCEPTEUR D'HYDROGÈNE DES THIOAMIDES

L'existence dans le groupement thioamidique des deux atomes qui possèdent des doublets électroniques libres (l'azote et le soufre) a conduit à des discussions contradictoires concernant l'atome qui peut fixer le proton.

Sur la base des résultats de quelques recherches effectuées dans le domaine des amides et thioamides, en utilisant la méthode spectrale (spectroscopie UV, IR, RMN) on a tiré la conclusion que la protonation a lieu au niveau de l'atome d'oxygène dans le cas des amides et au niveau de l'atome de soufre dans le cas des thioamides. [21]

Ainsi, comme on observe dans le tableau 2, les données indiquées montrent que les énergies de conjugaisons des deux formes protonées à l'atome de soufre, ou à l'atome d'azote sont différentes.

Dans tous les cas les valeurs ΔE sont plus grandes pour les formes protonées à l'atome de soufre, fait qui est en concordance avec les constatations expérimentales.

Les valeurs des indices de charges calculées pour l'atome de soufre et d'azote dans la forme thioamide et isothioamide mettent en évidence la différence entre ces deux formes à l'état fondamental et l'importance des effets électromères dynamiques dans la fixation d'un proton.

Les données indiquées dans le tableau 4 permettent de tirer quelques conclusions sur l'influence de la nature des radicaux et sur l'influence de la structure des thioamides VII, VIII et IX (tableau 5) grâce à laquelle ces thioamides sont fréquemment utilisés comme réactifs, pouvant former des complexes.

Les auteurs remercient encore une fois M. Mircea Gheorghiu, qui a eu l'amabilité de mettre à leur disposition le programme de calcul.

PEPTIDES. XII[*]

BEHAVIOUR OF THE MIXED ANHYDRIDES OF SOME AMINO ACIDS[**] N-PROTECTED WITH β-KETOESTERS

A. BALOG, D. BREAZU, VIORICA VOINESCU, MARGARETA HERMAN, E. VARGHA[**]
and E. RAMONŢIAN

Institute for Chemical and Pharmaceutical Research, Str. Fabricii 126, Cluj, Romania

Received March 6, 1972

The pivaloyl, isobutyroyl and benzoyl mixed anhydrides of AE– and CP–C-phenylglycines undergo at the pH 2 a simultaneous acyl migration and splitting of the AE or CP protecting groups, followed by the formation of the corresponding N-acyl C-phenyl-glycine (2). A similar reaction was observed in the case of the pivaloyl mixed anhydrides of some other AE-amino acids and by the benzoyl mixed anhydride of AE–L–PheOH. The mixed anhydrides formed from AE–Gly–OK and Phth–Gly–Cl leads by acyl migration to the dipeptide Phth–Gly–Gly–OH. The conditions in which the above reaction takes place without racemization, as well as the probable mechanism of the acyl migration are discussed.

In our earlier papers[1,2] we have shown the advantages presented in the peptide synthesis by the alkaline or dicyclohexylammonium salts of the amino acids N-protected with β-ketoesters or β-diketones, using the mixed anhydrides method. For the preparation of the mixed anhydrides, in the peptide synthesis we have used pivaloyl chloride, benzoyl chloride, ethyl chloroformate etc. The temperature was below – 5° and the reaction time 15–20 min. The formation of the mixed anhydride was performed by adding a drop of N-methylmorpholine.[3] Using for the aminolysis amino acid esters or peptide esters, the N-protected peptide esters could be obtained in high yields (over 70–80%).

---

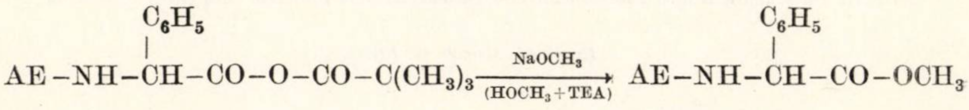
Under these conditions, a disproportionation of the mixed anhydrides to symmetric ones — a very frequent side reaction in the case of the N-acylamino acid mixed anhydrides — was not observed.

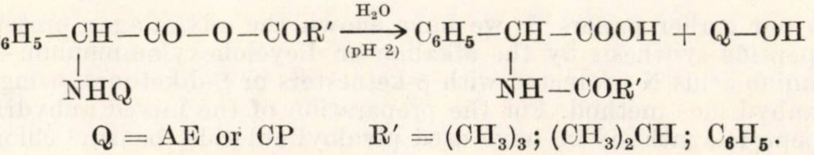
The mixed anhydrides of the amino acids N-protected with β-ketoesters or β-diketones react normally with sodium methoxide in benzene or with methanol in the presence of TEA. [4] Thus, the methanolysis of the AE—C-phenylglycyl-pivaloyl mixed anhydride leads to AE—C-phenylglycine methyl ester in 93% and respectively 74% yield.



$$\mathrm{AE{-}NH{-}\overset{\displaystyle C_6H_5}{\overset{|}{C}}H{-}CO{-}O{-}CO{-}C(CH_3)_3 \xrightarrow[(HOCH_3+TEA)]{NaOCH_3} AE{-}NH{-}\overset{\displaystyle C_6H_5}{\overset{|}{C}}H{-}CO{-}OCH_3} \qquad (1)$$

A partial racemization (12–13%) occurs during the esterification. When 20% excess of sodium methoxide was used a complete racemization was observed.

The mixed anhydrides of the amino acids N-protected with β-ketoesters show an interesting behaviour in acidic media. By treating their solution with hydrochloric acid to pH 2 a transposition takes place in which the acylic rest from the carboxyl migrates to the amino group, with the subsequent splitting of the N-protecting rest (AE or CP). In this way, the mixed anhydrides of the C-phenylglycine N-protected with acetoacetic or cyclopentanone-2-carboxylic ester yield N-acyl-C-phenylglycines (table 2).



$$\mathrm{C_6H_5{-}\underset{\displaystyle NHQ}{\underset{|}{C}}H{-}CO{-}O{-}COR' \xrightarrow[(pH\ 2)]{H_2O} C_6H_5{-}\underset{\displaystyle NH{-}COR'}{\underset{|}{C}}H{-}COOH + Q{-}OH} \qquad (2)$$

$\mathrm{Q = AE}$ or $\mathrm{CP} \qquad \mathrm{R' = (CH_3)_3;\ (CH_3)_2CH;\ C_6H_5}$.

The above reaction can be easily controlled by titration with alkali, when only one mole of hydroxide is consumed per mole of mixed anhydride. The acyl migration does not seem to be influenced by time, as the same quantity of the hydroxide was consumed at different intervals ranging from 5 to 240 minutes (table 1A). Nor seems the temperature to influence it sensibly, as the same results are obtained at temperatures between — 5° and + 25° (table 1B). It may be affirmed that under the above mentioned conditions no hydrolisis and disproportionation occur.

In order to check the final N-acylated products after the migration, we synthesized them by direct acylation methods. Physical constants of both products were identical.

When for the formation of the mixed anhydrides from dicyclohexylammonium salts of the C-phenylglycine N-protected with β-ketoesters a catalytic amount of N-methylmorpholyne was used, a complete racemization took place. This behaviour is due to the phenylglycine structure which has a special sensitivity towards racemization in the presence of bases.[5] In the absence of this catalyst it was necessary to extend the reaction time for the formation of the mixed anhydride from 5–10 minutes to 30 minutes. In this manner the N–TMA–D-phenylglycine was obtained by acylic migration with a high optical purity.

---

[4] D. A. Johnson, *J. Amer. Chem. Soc.*, **75**, 3636 (1953).

Table 1

The consumption of sodium hydroxide pro mole of mixed anhydride

A		B	
The reaction time min	NaOH consumption equivalent	Temperature °C	NaOH consumption equivalent
10	0.98	−5	0.96
60	0.96	0	1.27
120	0.97	+10	1.14
240	1.00	+25	1.08

A. The reaction was performed following the general method, at a temperature below 0°. The reaction time refers to the period between the acidulation and the alkaline titration of the reaction mixture.

B. After the acidulation to pH 2 the reaction time was in all cases 2 hrs.

If for the acidulation to pH 1,5 methanolic hydrochloric acid was added (anhydrous media) the acyl migration occurs as above. Using an excess of methanolic hydrochloric acid, the 0 → N acyl shift was followed by esterification with the formation of the N–TMA–C-phenylglycine methyl ester, identical with that prepared from N–TMA–C-phenylglycine and diazomethane.

We have also studied the acyl migration and the simultaneous splitting of the N-protecting group in the case of the pivaloyl mixed anhydride of the following amino acid derivatives: AE–GlyOH, AE–L–ValOH, AE–L–LeuOH and AE–L–IleOH. The reaction took place according to our expectations and the corresponding N-pivalic derivatives were obtained in overall yield 60% (table 2). The products were identified by direct acylation of the respective amino acids with pivaloyl chloride according to the Schotten-Baumann method.

In the case of the L-alanine and L-phenylalanine, the N-pivaloyl derivatives resulted by acyl migration could not be crystallized, but the mixed anhydride obtained from AE–PheOH and benzoyl chloride yielded N-benzoyl-L-phenylalanine (yield over 80%) identical with that mentioned in the litterature.[6]

---

[5] D. G. Neilson and D. F. Ewing, *J. Chem. Soc.*, **1966**, 393.

[6] M. Goodman and L. Levine, *J. Amer. Chem. Soc.*, **86**, 2918 (1964).

In the case of the mixed anhydride obtained from the AE—Gly—OK and phthaloylglycyl chloride the acyl migration followed by the splitting of the N-protecting group (AE) led to N-phthaloylglycyl-glycine

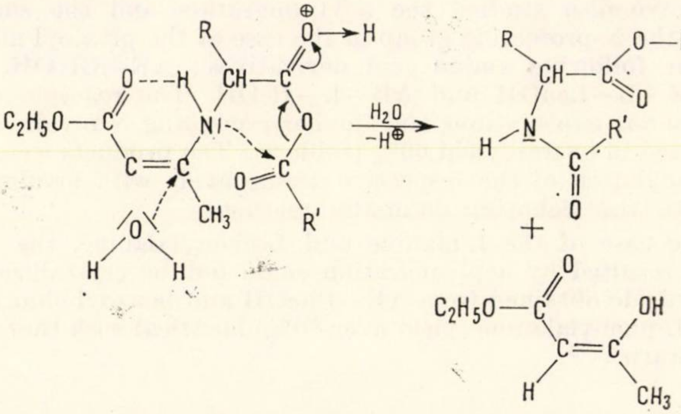
$$\mathrm{AE-NH-CH_2-COOK} \xrightarrow{\mathrm{Cl-CO-CH_2-NPhth}} \mathrm{AE-NH-CH_2-CO-O-CO-}$$

$$\mathrm{-CH_2-NPhth} \xrightarrow[(\mathrm{pH}=2)]{\mathrm{H_2O+}} \mathrm{PhthN-CH_2-CO-NH-CH_2CO_2H} \qquad (3)$$

The melting point of our product was lower with 14—15° than that described[7] owing to the presence of the N-phthaloylglycine, that could not be removed not even by repeated recrystallizations. The product (m.p. 216—218°) was converted by means of the cyanomethyl tosylate[2] into N-phthaloylglycyl-glycine cyanomethyl ester, identical with the same derivative obtained[2] from glycine cyanomethyl ester hydrochloride and phthaloylglycyl chloride.

Regarding the mechanism of the acyl migration described here, it seems reasonable to admit a certain analogy with the intramolecular transposition observed by Weygand and co-workers[8,9] in the case of symmetric anhydride of glycine or alanine N-protected with trifluoroacetyl group. The transposition takes place in the presence of ethanolic dicyclohexylamine and leads to the corresponding N-trifluoroacetyl dipeptide and ethyl trifluoroacetate.

In our case, the migration occurs under the catalytic action of acids and follows also an intramolecular mechanism: yields are high and no disproportionation or dipeptide formation was observed. It can be presumed that in the first step a protonated form (I) of the anhydride group appears[10] which allows the nucleophilic attack of the nitrogen on the acid partner's carbonyl



---

[8] F. Weygand and M. Reiher, *Chem. Ber.*, **88**, 26 (1955).

[9] F. Weygand and U. Glöchler, *ibid.*, **89**, 653 (1956).

[10] V. Gold and J. Hilton. *J. Chem. Soc.*, **1955**, 843.

On the other hand, the nucleophilic character of the nitrogen atom is strengthened by the enaminic form, which supposes an intramolecular hydrogen bond. In the next step, the acylation of the amino group takes place with subsequent reforming of the carboxyl group and the hydrolytic removal of the protecting group.

The acyl migration observed by the mixed anhydrides of the amino acids N-protected with β-ketoesters has not a general character. Thus, it does not occur in the case of the mixed anhydrides of the C-phenylglycine N-protected with benzoylacetone or 2,6-dimetoxybenzoylacetone, because of the marked stability of the protecting groups. [1]

EXPERIMENTAL

All melting points were performed in glass capillaries and are uncorrected. The analytical samples were dried over P_2O_5 for 3—4 hrs at 64° and 16—20 Torr. The specific rotations were determined in tubes of 2 dm at 20—24° (Metra 400/a-Prague polarimeter).

1. *Acyl-migration. General method.* 10 mmoles of potassium or dicyclohexylammonium salt of the amino acid N-protected with acetylacetic, respectively, cyclopentanon-2-carboxylic ester was dissolved in 40 ml of THF and cooled in ice-salt bath for 4—5 min. 10 mmoles of acid chloride (1.2 ml pivaloyl or benzoyl chloride) was added and the mixture was cooled further for 15 min. The formed precipitate (consisting in potassium or dicyclohexylammonium chloride) was filtered and washed three times with THF.

The cooled solution of the mixed anhydride was treated with hydrochloric acid 25% to pH 1.5—2. After standing for 1 hr with cooling and 1 hr at room temperature, the mixture was concentrated in vacuum to 1/5 of the volume. A light excess of 5% sodium bicarbonate was added. The aqueous solution was extracted twice with ether and acidulated to pH 1—2. The N-acylamino acid precipitated by storage and cooling was filtered and dried. The raw product was crystallized from an adequate solvent (see Table 2).

2. *N-Pivaloyl-C-phenylglycine.* a) The mixed anhydride was prepared from 1.6 g (5 mmoles) of *potassium N-(1-ethoxy-carbonyl-propen-2-yl)-D-phenylglycinate* and 0.6 ml pivaloyl chloride in 30 ml THF, following the above described method. After treatment with hydrochloric acid, the usual work-up afforded 0.75 g (74%) of *N-pivaloyl-D-phenylglycine*, melting at 133—134°.

b) In the same way, but using a drop of N-methylmorpholine as catalyst for the formation of the mixed anhydride, after the transposition, 0.8 g (83%) N-pivaloyl-DL-phenylglycine was obtained $[\alpha]_D = 0°$ ($c = 1$, EtOH); m.p. 152—153° (from aqueous ethanol); mixed melting point with a sample prepared following the Schotteng-Baumann method did not depress.

		C	H	N	
$C_{13}H_{17}NO_3$ (235.3)	Calcd.	66.31	7.28	5.95	
	Found	66.52	7.83	6.02	(Kjeldahl)

c) The mixed anhydride was prepared according to the 2.*a* (from 2.35 g (5 mmoles) of *dicyclohexylammonium N-(2-ethoxycarbonyl-cyclopenten-l-yl)-phenylglycinate*. After the filtration of the dicyclohexylammonium hydrochloride, the solution of the mixed anhydride was treated with 25% methanolic hydrochloric acid to pH 1.5. The work-up following the general method gave 0.8 g (68%) of *N-pivaloyl-D-phenylglycine*. $[\alpha]_D$: —167° ($c = 1$, ethanol); m.p. 133—136°, without depression by mixing with the sample obtained according to *Schotten-Baumann*'s method.

3. *N-Pivaloyl-C-phenylglycine methyl ester.* a) The mixed anhydride was prepared following the 2. *b*) and after filtration, the solution was treated with an excess of 25 % methanolic hydrochloric acid (5 ml). After 30 minutes cooling and 1 hour storage at room temperature, the reaction mixture was washed successively with water, 5 % sodium bicarbonate solution, water. The organic layer was dried over Na_2SO_4. After the removal of the solvent and the recrystallization of the residue 0.9 g (72 %) of *N-pivaloyl-DL-phenylglycine methyl ester* was obtained; $[\alpha]_D$: 0° ($c = 1$, methanol); m.p. 148–149° (ethanol).

$C_{14}H_{19}NO_3$ (249.2)	Calcd.	C 67.45	H 7.68	N 5.64
	Found	67.25	8.00	5.60

b) The methylic ester obtained from *N-Pivaloyl-DL-C-phenylglycine* and ethereal diazomethane presented m.p. 148.5–149° and showed no depression when mixed with the above product.

4. *Phthaloyl-glycylglycine.* 2.3 g (10 mmoles) of *potassium N-(1-ethoxycarbonyl-propen-2-yl)-glycinate* suspended in 25 ml of acetonitrile was treated dropwise under stirring and cooling at – 5°, with 2.2 g (10 mmoles) of phthaloylglycyl chloride dissolved in 15 ml of acetonitrile. After a standing of 1 hour 2 N hydrochloric acid was added slowly to pH 2. The stirring was continued for 30 minutes at – 5° and for 30 minutes at room temperature. Addition of 30 ml water yielded a white precipitate that was filtered and washed successively with water and methanol.

After recrystallization from water resulted 2.1 g (81 %) product with m.p. 216–218° (after two recryst, from water Lit. [7] indicates for the same product m.p. 230–233°.

N-Phthaloyl-glycylglycine cyanomethyl ester. 0.8 g (3 mmoles) of phthaloyl-glycylglycine obtained as above was suspended in 5 ml of anhydrous acetone and was treated with 0.45 ml of TEA and 0.6 g (3 mmoles) of cyanomethyl tosylate.

The mixture was stirred for 2 hours. The precipitate formed by adding 75 ml water was filtered and dried. Yield 0.72 g (80 %); m.p. 203–204° (from ethanol) without depression by mixing with the ester obtained from glycine cyanomethyl ester hydrochloride and phthaloylglycine chloride. [2]

5. *The methanolysis of the mixed anhydrides.*

N-(1-Ethoxycarbonyl-propen-2-yl)-C-phenylglycine methyl ester. The mixed anhydride, obtained following the general method from 10 mmoles of AE-D-phenylglycine potassium salt and 1.2 ml of pivaloyl chloride, was treated at – 10° with 110 ml 0.1 N benzenic solution of sodium methoxide. The mixture was stirred for 1 hour and was allowed to stand for several hours at room temperature. The solvent was removed under *vacuum*. By treating the gelatinous residue with water, 2.6 g (93 %) of raw ester was precipitated, m.p. 67–91°. After recrystallization from light benzine (b.p. 60–80°) m.p. 75–76°; $[\alpha]_D^{20} + 191°$ ($c = 1$, methanol). The same product obtained using methyl tosylate according to literature [2] has m.p. 80–81° and $[\alpha]_D^{20} + 259°$ ($c = 1$, methanol).

b) The mixed anhydride obtained as described before at *a*) was treated, under cooling in ice-salt bath, with 1.5 ml methanol and 1.6 ml TEA. After 6 hours storage at room temperature the reaction mixture was poured into water (200 ml). The separated oil solidified gradually yielding 2.05 g (74 %) product with m.p. 75–76° (benzine).

Note. The use of 10–20 % excess of sodium methoxide afforded the DL-product, m.p. 101–102° (benzine); $[\alpha]_D^{21}$: 0° (m.p. according to lit. [2] : 104–105°)

KINETICS OF SOLVOLYTIC REACTIONS. IV.[1]

TRANSITION STATE IN THE π-ROUTE OF THE ACETOLYSIS OF 5H-DIBENZO [a, d]-CYCLOHEPTEN-5-YL-(β-ETHYL) TOSYLATE

M. VOICU*, F. BADEA * and ANCA VOICU **

Organic Chemistry Laboratory,

Received July 31, 1972

5H-Dibenzo [a, d] cyclohepten-5-yl-(β-ethyl) tosylates, **1**, substituted in the *para* position in benzene ring with respect to the double bond, were prepared. Rate constants for the acetolysis, activation parameters, salt effects, and variation of the ratio of uncyclized (*B*), to cyclized products (*C*), with the sodium acetate concentration, were studied. The ratio *B*/*C* varies linearly with the sodium acetate concentration, as has been previously observed for the unsubstituted tosylate, **1**–H. The assisted rate constants and *R* terms (equation 2) are well correlated in a $\rho-\sigma^n$ treatment; these are discussed as evidence for a bridged transition state in the π-route reaction.

In the acetolysis of the tosylate **1**–H, two types of reaction products are formed[2]: the unrearranged acetate **2**(*B*), on the one hand, and the bridged products **3**(*C*), on the other hand. The formation of the latter products involves the double bond (π-route).

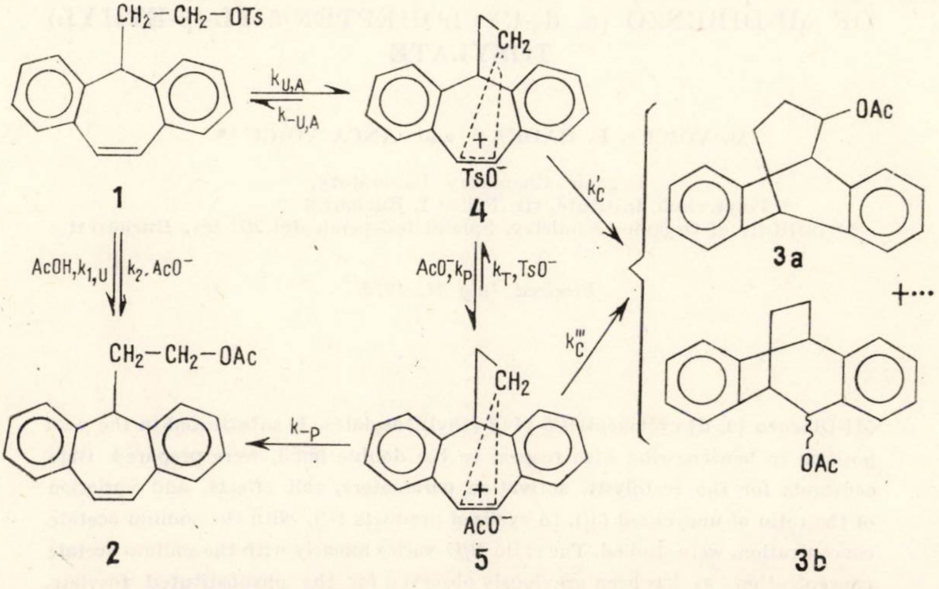
[2] E. Ciorănescu, M. Banciu, R. Jelescu, M. Rentzea, M. Elian and C. D. Nenitzescu, *Rev. Roumaine Chim.*, **14**, 911 (1969).

The kinetic treatment of the NaOAc-buffered acetolysis has revealed that sodium acetate is involved in the formation of all reaction products,[3] the mechanism depicted in Chart I being in good agreement with the published results.

Chart I



According to that reaction mechanism, the ratio between the unrearranged and rearranged products (B/C) is given by relationship[3] (1)

$$\frac{B}{C}=\frac{k_{1,\mathrm{U}}}{k_{\mathrm{U,A}}}+\left[\frac{k_{\mathrm{P}}/k'_{\mathrm{C}}}{1+k'''_{\mathrm{C}}/k_{-\mathrm{P}}}+\frac{k_2}{k_{\mathrm{U,A}}}\right]\cdot[\mathrm{NaOAc}] \qquad (1)$$

in which $k_{1,\mathrm{U}}$, $k_{\mathrm{U,A}}$ and k_2 can be appreciated from the kinetic data and the plot of the ratio B/C *vs* the concentration of sodium acetate. From the same plot the term R can be calculated:

$$R=\frac{k_{\mathrm{P}}/k'_{\mathrm{C}}}{1+k'''_{\mathrm{C}}/k_{-\mathrm{P}}} \qquad (2)$$

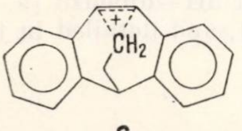
It was considered that this term measures the relative stability of the intermediate[3] of the π-route.

In an effort to find other examples which would satisfy the relationships (1) and (2), ring substituted derivatives of **1**—H (**1**—X, X = Cl, CH_3 and CH_3O) have been studied in this work. It was hoped that if relationship (1) holds up in these cases too, a better understanding of the R

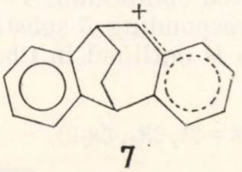
---

[3] M. Voicu and F. Badea, *Rev. Roumaine Chim.*, **14**, 929 (1969).

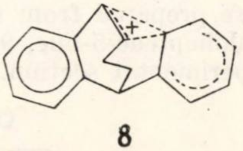
factor could be acquired. It was anticipated that the free energy relationships could give a better hint regarding the structure of the first formed intermediate. Indeed, in Chart I, the cation in the ion pairs **4** and **5** was considered to be the bridged ion **6**. However, the nature of the rearranged formed products are also in agreement with a benzylic ion **7**, or with a phenonium ion **8**.



6



7



8

Bartlett and Sargent[4] pointed out some time ago: "in view of the difficulty of examining the structures of short lived ions, and the greater difficulty of examining transition states, the effect of substitution at different sites may be the best available criterion of the nature of the transition state in an ionization". In this respect, the substitution of the aromatic rings in **1**$-$X seemed to us promising.

It is well known that the solvolysis of benzylic derivatives is best correlated with Brown's σ^+ constants,[5] high negative reaction constants ρ being observed[6] (*t*-cumyl chloride, $\rho = -4.9$; 1-phenylcyclopentyl chloride, $\rho = -4.5$; 2-phenyl-2-*exo*-norbornyl chloride, $\rho = -4.3$). A similar correlation with $k_{U,A}$ values should be checked up if the benzylic ion **7** would be formed in the rate determining step.

For phenonium ion reactions, similar free energy relationships have been observed, the reaction constants ρ being comparatively lower than the values observed in benzylic ion reactions (6- and 7-substituted benzonorbornen-2-*exo*-yl brosylates,[7] $\rho = -3.3$ or[8] -2.8; neophyl brosylates,[9] $\rho = -3.0$; 6, 7-disubstituted- *anti*-9-benzonorbornenyl brosylates,[10] $\rho = -2.6$; 6-substituted-*anti*-9-benzonorbornenyl brosylates,[11] $\rho = -2.4$). The rate constants, at least for the *p*-methoxy derivatives, are greater than for the $\rho - \sigma$ treatment (*trans*-2-arylcyclopentyl tosylate[12]; 1-aryl-2-propyl tosylate[13]; 2-arylethyl tosylate[14]). If the phenonium ion **8** is formed in the rate determining step of the solvolysis of **1**$-$X derivatives, a value of the reaction constant of about -2 or -3 should be expected.

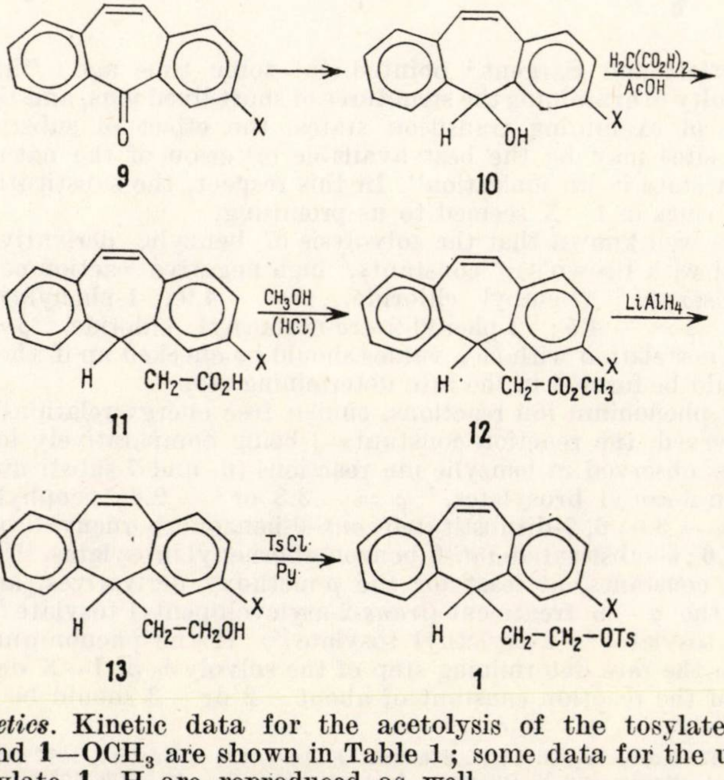
[14] M. G. Jones and J. L. Coke, *J. Amer. Chem. Soc.*, **91**, 4284 (1969).

Smaller absolute values of the ρ constants ($|\rho| \ll 2$) should be observed if the bridged ion **6** is initially formed, the delocalization of the positive charge in ion **6** being less important as in the ions **7** and **8**.

RESULTS

Syntheses. The substituted compounds **1**$-$Cl, **1**$-CH_3$ and **1**$-OCH_3$ were prepared from the corresponding 3-substituted 5H$-$dibenzo [a, d] cycloheptene-5-one, 9$-$X, as is outlined in Chart II, and detailed in the experimental section.

Chart II ($X = Cl, CH_3, CH_3O$)



Kinetics. Kinetic data for the acetolysis of the tosylates **1**$-$Cl, **1**$-CH_3$ and **1**$-OCH_3$ are shown in Table 1; some data for the unsubstituted tosylate **1**$-$H are reproduced as well.

Reaction products. No attempt has been undertaken to prove the exact structure of the reaction products formed in the acetolysis of **1**$-$Cl, **1**$-CH_3$ and **1**$-OCH_3$. The ratio between the unrearranged and rearranged products, B/C, was determined spectrophotometrically on the absorbtion of stilbene system in B, [3] as a function of the concentration of the added sodium acetate. The results are plotted in Figure 1.

From the observed kinetics in the absence of sodium acetate (Table 1), and the intercept of the straight lines in figure 1, the assisted rate constants, $k_{U,A}$, and the pseudounimolecular rate constants, $k_{1,U}$ could be calculated (Table 2).

a) Spectrophotometric measurements ; b) Ref. 3 ; c) Normal salt effect.[15]

The terms R could be calculated from the slopes of the straight lines in Figure 1, if the values of the bimolecular rate constants, k_2, are known. It has been shown previously,[3] that both $k_{1,\mathrm{U}}$ and k_2 can be determined from the corresponding rate constants $k_{1,\mathrm{S}}$, $k_{2,\mathrm{S}}$ of the saturated analogue **14**.

	OCH_3	0.185	0.461	33.0	0.662	3.58	0.36

a) k_S is the rate constant of the saturated unsubstituted compound, **14**, assuming that it is regardless of the substituent (see the following discussion in the text) ; $k_S = 1.34\cdot 10^{-5}$ sec^{-1}, at 110°, Ref. [3].

Pritzkow and Schöppler[16] have shown that the bimolecular rate constants of the reaction of the primary tosilates, $R-CH_2-OTs$ with acetate ion in acetic acid are only slightly affected by the nature of the α radical, R : in our reaction, a slight structural change occurs in the γ substituent of a γ—Ar′ γ-Ar-propyl linkage. It is therefore reasonable to assume that the rate constant k_2, would be not seriously affected by the nature of the substituent in one of the γ-aryl rings. The R values from Table 2 were thus calculated from the known value k_2, for the unsubstituted saturated derivative, **14**.

DISCUSSIONS

THE ASSISTED IONIZATION OF 1–X DERIVATIVES

The validity of relationship (1) was also confirmed by the herein reported results. The ratio between the unrearranged and rearranged products (B/C) varies linearly with the sodium acetate concentration in the substituted series (**1**–X, X=Cl, CH_3, OCH_3), as it does in the case of the unsubstituted tosylate, [3] **1**–H. The observed rate constants increase as the electron-repelling effect of the substituent in the aromatic ring is increasing, indicating a charge delocalization in the aromatic ring in the rate determining step. However, the assisted rate constants, $k_{U,A}$ (Table 2) are not correlated with σ^+ values, excluding thus the formation of a benzylic ion **7** in the rate determining step. The data recorded in Table 2 are best fitted with σ^n values, [17] indicating either a phenonium ion **8**, or a bridged ion **6** (Figure 2).

The small negative value ($\rho_{U,A} = -1.17$) of the slope of the correlation line in Figure 2, rules out the phenonium ion **8**, and suggests, as the most probable intermediate of the initial step, the bridged ion **6**. As Bartlett and Sargent have shown, [4] the rate of the formation of bridged ions in π-route reactions depends upon the nucleophilicity of the double bond; the reactivity of the double bond in **1**–X derivatives is expected to be modified by the inductive effect of the substituent in the aromatic ring, in perfect agreement with the observed $\rho_{U,A}$ value.

The analysis of the term R (2) is another proof for the mechanism given in Chart I. This term can be splitted into two factors, a stability factor, S, and a delocalization factor, D :

$$R = \frac{k_P}{k'_C} \cdot \frac{k_{-P}}{k_{-P} + k'''_C} = S \cdot D \qquad (5)$$

The first factor, $S = k_P/k'_C$, measures the ability of the ion pair **4** to discern between different nucleophiles (NaOAc and AcOH, respectively); its value will be greater, the greater the stability of the ion pair.

The delocalization factor, $D = k_{-P}/(k_{-P} + k'''_C)$, represents the molar fraction of the ion pair **5** which reacts to give the unrearranged acetate, B. Its value depends upon the charge distribution in the bridged ion **6**–X; the smaller its value, the greater the charge in the ω position.

---

[17] M. van Bekkum, P. E. Verkade and B. M. Wepster, *Rec. Trav. chim.*, **78**, 815 (1959).

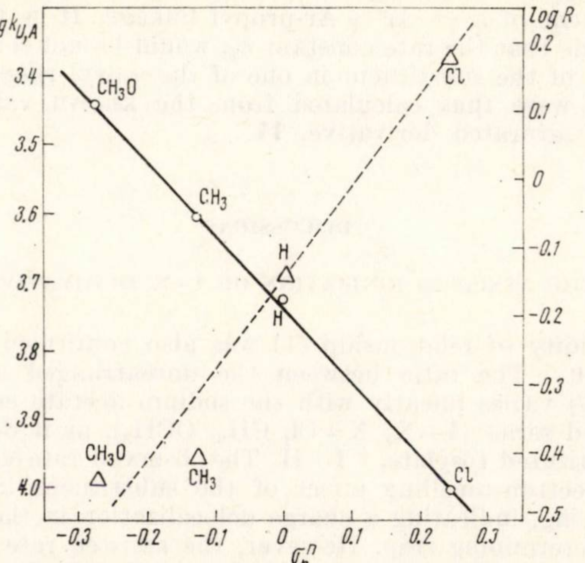

Fig. 2. — The $\rho - \sigma^n$ treatment of the anchimerically assisted rate constants. $k_{U,A}$, at 110° (solid line; $_{U,A}\rho = -1.17$, $r = 0.99$), and of the relative stability factor, R (dashed line; $\rho_R = +1.22$, $r = 0.86$), in the acetolyses of the tosylates **1**.

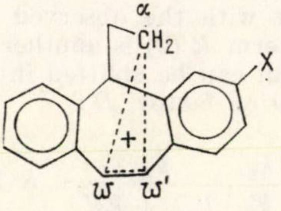
The delocalization factor, D, measures also the weight of the retro-π-route in this system *).

The R values given in Table 2 seem to be governed by the D-factors. Indeed, it is expected that the charge in the ω position will be more developed in **6**—OCH$_3$ (smallest R-value), and less developed in **6**—Cl (highest R-value), in agreement with the calculated R-values.



6—X

Similar stability factors, $S = k_P/k'_C$, are expected for bridged ions, **6**—X, but very different values should be anticipated for benzylic ion **7**.

---

*) Felkin and Lion[18] claimed to have discovered the first example of a retro-π-route reaction. Our previous work[3] have already discussed the retro-π-route observed[2] in the acetolysis of the 5H-dibenzo[a, d] cyclohepten-5-yl(β-ethyl) tosylate, **1**—H.

[18] H. Felkin and C. Lion, *Tetrahedron*, **27**, 1375 (1971).

If the stability factors are not very different from each other, a linear free energy relationship of the *R* terms is expected, and this will be essentially a *D*-factor correlation.

D-factors measure also the disappearance of the developed charge in the ionization step. The *R* terms should therefore correlate in their turn with σ^n values, and the sign of the ρ_R parameter should be positive. This was really found to be the case : $\rho_R = +1.22$ (Fig. 2).

Neither from relation (5), nor from figure 3a, it could not have been expected the nearly perfect identity between the absolute values of ρ_R and $\rho_{U,A}$. Indeed, the transition state for the formation of the unrearranged acetate **2** from the ion pair **5** should not be very different from the transition state of the return from the ion pair **4** (Hammond's postulate [19]). A smaller positive value than the absolute value of $\rho_{U,A}$ should have been expected for ρ_R.

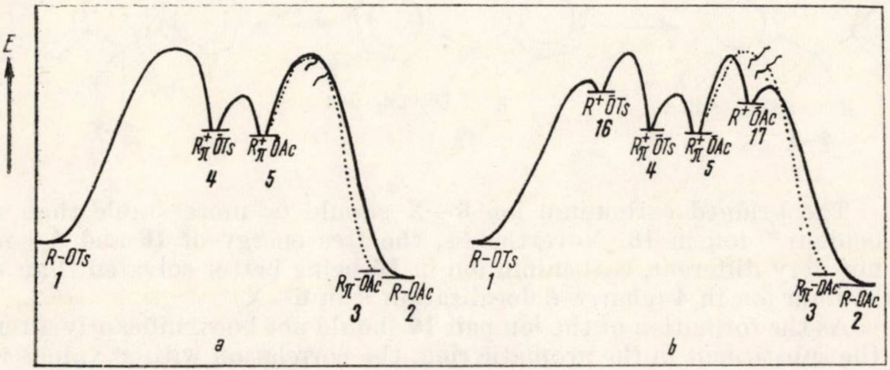


Fig. 3. — Potential energy plot for the acetolysis of **1**$-$X derivatives. a. According Chart I (assisted ionization); b. According Chart III (unassisted ionization).

The found equality

$$|\rho_{U,A}| \approx |\rho_R| \tag{6}$$

is easily interpreted (Figure 3 b), if the mechanism depicted in Chart I is only slightly modified.

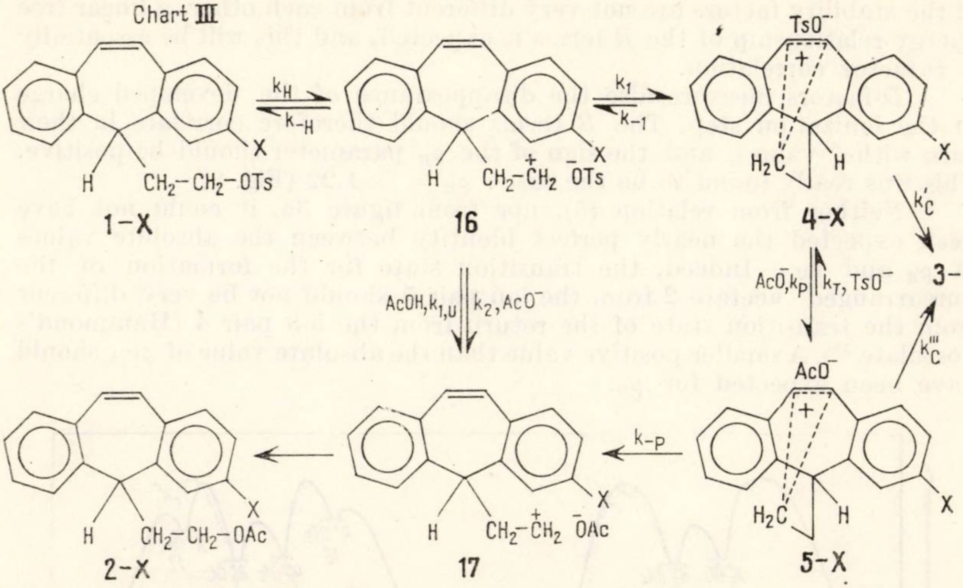
$$k_{U,A} = \frac{k_H}{k_{-H}} \cdot k_1 = K_H \cdot k_1 \tag{7}$$

According to Chart III, the initial ionization is not assisted by the double bond, a tight ion pair, **16**, being thus formed. ***The observed anchimeric assistance of the double bond is thus the result of the rearrangement of the ion pair* 16 *in the bridged ion pair* 4*, which lowers the weight of the reversible reaction,*** k_{-H}.

---

[19] G. S. Hammond, *J. Amer. Chem. Soc.*, **77**, 334 (1955).

Chart III



The bridged carbonium ion **6**−X should be more stable than the carbenium[20] ion in **16**. Nevertheless, the free energy of **16** and **4** could be not very different, carbenium ion in **16** being better solvated than the carbonium ion in **4** (charge delocalization[21] in **6**−X).

As the formation of the ion pair **16** should not be significantly altered by the substituent in the aromatic ring, the correlation with σ^n values will depend upon the second step (the formation of the bridged ion pair **4**), and this step would be similar to the reverse reaction, **5**−X → **17** (see Chart III and Figure 3b).

Our interpretation of the anchimeric assistance is in agreement with other known data which will be discussed in another paper.

THE BIMOLECULAR ROUTES IN THE FORMATION OF UNCYCLIZED PRODUCT

The bimolecular routes in the formation of the uncyclized product, **2**−X, labelled in Chart I with $k_{1,U}$ for AcOH and k_2 for AcO- are not essentially different from the retro-π-route in formation of **2**. According to Chart III, either tight ion pair **16**, or ion pair **4** can react with NaOAc. The direct formation of **2**−X from **16**, or the rearrangement of **16** into **4** are similar ; in both reactions, a carbenium ion center in **16** is either captured by a double bond, or by another nucleophile, NaOAc.

The pseudounimolecular reaction ($k_{1,U}$ in Table 2), deserves some further comments. Both electron-repelling and attracting substituents increase the rate constant, $k_{1,U}$ for the unsubstituted derivative, **1**−H.

---

[20] G. A. Olah, *J. Amer. Chem. Soc.*, **94**, 808 (1972).

[21] H. C. Brown, *Chem. Soc. (London), Special Publ.*, **16**, 140 (1962).

The last three rate constants $k_{1,U}$ in Table 2 (X=H, CH_3 and OCH_3) correlate with Brown's σ^+ parameters; the slope, $\rho = -0.52$ agrees fairly well with the ρ parameters for the *ortho*-alkylation of toluene[22] ($\rho = -0.45 .. -0.62$). The capture of the carbenium ion center in **16** by the neighbouring aromatic rings could be an explanation; an Ar_2-5 assisted solvolysis seems attractive. However, the small ratio of this reaction in the overall process of the 1–X acetolysis has not enabled us to bring some other support of that mechanism.

Unimolecular ionization in acidic solvents such as carboxylic acids must be a general route in the solvolysis, even if the radical carrying the leaving group is a primary one. The validity of this assumption is confirmed by the similar ρ values of the NaOAc-buffered acetolysis of primary tosylates (a value $\rho = +1$ can be calculated from the data published by Pritzkow and Schöppler[16]) and the value $\rho_{U,A} = -1.17$ ($\rho_{U,A}$ measures the change in the nucleophile, the double bond, and should therefore have an inverted sign).

EXPERIMENTAL

Melting points are uncorrected. IR spectra were recorded with a double-beam Jena U.R.–20 spectrophotometer. NMR spectra were obtained on a Varian A–60A spectrometer, using TMS as internal standard.

3-Substituted-5H-dibenzo [*a, d*] *cyclohepten-5-ones*, **9**, are known compounds : **9**–Cl[23]; **9**–CH_3[23]; **9**–OCH_3.[24]

3-Substituted-5H-dibenzo [*a, d*] *cyclohepten-5-ols*, **10** :

– **10**–CH_3[25] and **10**–OCH_3[24] are known compounds;

– **10**–Cl was prepared by reducing **9**–Cl with sodium borohydride in methanol, as **10**–CH_3[25]. After two recrystallizations from ligroin, **10**–Cl melted at 140–2°. Anal. : Found : C, 73.31 ; H, 4.70 ; Cl, 15.30. Calcd. for $C_{15}H_{11}ClO$: C, 74,23 ; H, 4.57 ; Cl, 14,61 %. IR spectrum (CCl_4, cm^{-1}) : 1045 s, 3638 s.

3-Substituted-5H-dibenzo [*a, d*] *cyclohepten-5-yl-acetic acids*, **11**. The used procedure is based on that reported earlier [26,2] for the unsubstituted acid, **11**—H.

A solution of **10**–X and malonic acid in anhydrous acetic acid (molar ratio, 1 : 2 : 50) was heated under reflux for 20 hrs. Evaporation under reduced pressure gave an oily residue which was dissolved in ether. The resulting solution was extracted with a 10 % sodium hydroxide solution. When acidified with hydrochloric acid under cooling, a crystalline precipitate appeared.

– **11**–Cl : 97 % yield, m.p. 158–9° (ethanol-water, 2 : 1). Anal. : Found : C, 71.45 ; H, 4.87 ; Cl, 12.64. Calcd. for $C_{17}H_{13}ClO_2$: C, 71.71 ; H, 4.61 ; Cl, 12.45 %. IR spectrum (CS_2, cm^{-1}) : 735 m, 760 m, 786 s, 830 s, 1710 vs, 2600–3200 m, broad.

—**11**—OCH_3 : 80% yield, m.p. 158—9° (ethanol, 90%). Anal. : Found . C, 76.39 ; H, 5.90. Calcd. for $C_{18}H_{16}O_3$: C, 76.11 ; H, 6.07%.

Methyl esters of 3-substituted-5H-dibenzo [a, d] cyclohepten-5-yl-acetic acids, **12**.

The corresponding acid **11** was dissolved in methanol (molar ratio, 1 : 200) previously saturated with gaseous hydrochloric acid. This solution was refluxed for 20 hrs. Most of the alcohol was removed by distillation (reduced pressure, steam bath), and the resulting solution was diluted with ether. This extract was washed with water, then with a 10% sodium carbonate solution, again with water, and dried over anhydrous sodium sulfate. The solvent was removed under reduced pressure, yielding a colourless oil.

— **12**—Cl : virtually quantitative yield, m.p. 52—3° (methanol). Anal. : Found : C, 72.25 ; H, 5.28 ; Cl, 12.21. Calcd. for $C_{18}H_{15}ClO_2$: C, 72.36 ; H, 5.06 ; Cl, 11.87%. IR spectrum (CCl_4, cm^{-1}) : 1165vs, 1247vs, 1300s, 1743vs.

— **12**—CH_3 : 92% yield. Anal. : Found : C, 81.22 ; H, 6.91. Calcd. for $C_{19}H_{18}O_2$: C, 81.99 ; H, 6.52%.

— **12**—OCH_3 : 90% yield. IR spectrum (CCl_4, cm^{-1}) : 1159s, 1263s, 1743vs.

3-Substituted-5H-dibenzo [a, d] cyclohepten-5-yl-(β-ethanol), **13**.

A solution of **12** in anhydrous ether was added for a period of 3/4 hr to a stirred mixture of an equal amount of lithium aluminium hydride and ether. The mixture was heated at reflux for 2 hrs, and left overnight, then cooled with ice, and a 10% solution of sulfuric acid was then added. The aqueous layer was extracted four times with ether. The combined organic layers were washed with water and dried over anhydrous sodium sulfate. The solvent was removed under reduced pressure to give a colourless liquid in virtually quantitative yield. The NMR data listed in Table 3 were in agreement with the assigned position of the substituent.

— **13**—Cl : The vapour phase chromatogram showed a major peak (98.8% of total area). Anal. : Found : C, 74.36 ; H, 5.94 ; Cl, 11.92. Calcd. for $C_{17}H_{15}ClO$: C, 75.41 ; H, 5.59 ; Cl, 13.09%. IR spectrum (CCl_4, cm^{-1}) : 1040vs, 3648 m.

—**13**—CH_3 : m.p. 68—9° (ethanol). The vapour phase chromatogram of this material showed a major peak (95.3% of total area). Anal. : Found : C, 85.88 ; H, 7.29. Calcd. for $C_{18}H_{18}O$: C, 86.36 ; H, 7.25%. IR spectrum (CCl_4, cm^{-1}) : 1040vs, 3648m.

— **13**—OCH_3 : The vapour phase chromatogram showed a major peak (94.9% of total area). Anal. : Found : C, 80.65 ; H, 7.21. Calcd. for $C_{18}H_{18}O_2$: C, 81.16 ; H, 6.76%. IR spectrum (CCl_4, cm^{-1}) : 1041vs, 3639m.

Tosylates of 3-substituted-5H-dibenzo [a, d] cyclohepten-5-yl-(β-ethanol), **1**. The tosylates **1**—Cl and **1**—CH_3 were prepared essentially following the mentioned procedure [2] for the unsubstituted tosylate, **1**—H.

The alcohol **13** was dissolved in dry pyridine, and solid *p*-toluenesulfonyl chloride (molar ratio, 1 : 40 : 1.1) was added. The mixture was swirled until all the chloride had dissolved. The solution was kept at 0° for 4 days, during which time large crystals of pyridine hydrocloride formed. A solution of ice-water and hydrochloric acid was added and the mixture extracted three times with methylene chloride. The combined extracts were washed successively with dilute hydrochloric acid, water, diluted sodium carbonate solution, and water ; the solution was then dried over anhydrous magnesium sulfate, and methylene chloride was removed at 30° under reduced pressure. A clear oil separated ; after several days this oil solidified to produce white needles of tosylate.

---

[27] R. Huisgen and G. Seidl, *Chem. Ber.*, **96**, 2740 (1963).

The ratio of the uncyclized to cyclized products, B/C, was measured spectrophotometrically, [3] taking advantage of the 293 mμ absorption band corresponding to the stilbene system of the compounds **1** and **2**. The applicability of the Lambert-Beer's law was verified. The extinction coefficients are : $\varepsilon_{1-\mathrm{Cl}} = 15{,}030$; $\varepsilon_{1-\mathrm{CH_3}} = 13{,}460$; $\varepsilon_{1-\mathrm{OCH_3}} = 13{,}150$.

When the reaction is completed (more than ten half-lives), the ratio of the uncyclized to cyclized products (the double bond is involved in the formation of the cyclized products and they do not contain the stilbene system) was calculated from the equation [3] :

$$\left(\frac{B}{C}\right)_{\infty} = \frac{E_{\infty}}{E_0 - E_{\infty}} \tag{8}$$

Kinetic measurements were performed in anhydrous acetic acid containing a small amount of acetic anhydride. [3] Sodium acetate solutions were obtained as is previously described.[3] Solutions of desired concentration (about 10^{-5} moles/l) of tosylate were transferred in sealed tubes and thermostated. They were withdrawn at appropriate intervals, chilled at room temperature (in these conditions the reaction is practically quenched) and the content was introduced in spectrophotometric cuve. As the constance of the *B/C* ratio during the reaction time had been demonstrated in these cases, the rate constants were calculated from the equation (9), which gave the real constant :

$$k = \frac{2.303}{t} \log \frac{E_0 - E_{\infty}}{E - E_{\infty}} \tag{9}$$

Acknowledgements. The authors wish to express their special gratitude to Professor Ecaterina Ciorănescu-Nenitzescu for helpful guidance throughout the progress of this research. They thank Miss E. Sliam and Mrs. V. Daniel for elementary analyses, M. Elian for IR spectra and F. Chiraleu for NMR spectra.

CHARACTERIZATION OF THE CERAMIC ION-SELECTIVE MEMBRANE-ELECTRODES. IV *

INFLUENCE OF THE OBTAINING CONDITIONS OF Ag_2S MEMBRANE UPON THE WORKING OF Ag^+-SELECTIVE MEMBRANE-ELECTRODE

I. C. POPESCU, C. LITEANU and V. CIOVÎRNACHE

"Babeş-Bolyai" University, Department of Analytical Chemistry,
Str. Arany János 11, Cluj, Romania

Received March 11, 1972

Results of a detailed study concerning the influence of the obtaining conditions of the Ag_2S ceramic membrane (granulation, pressing pressure and membrane thickness) upon the electrode function and electric resistance of Ag_2S membrane-electrode are presented. Statistical interpretation of the experimental results leads to the conclusion that in the region explored the parameters studied do not affect the electrode function of the Ag^+-selective membrane-electrode.

In a previous paper some characteristics and applying of a new type of Ag^+-selective membrane-electrode has been shown. [1]

The functional element which gives the selectivity of the membrane electrode, is made of Ag_2S powder. By quasi-stationary double faced pressing this gives a rigid ceramic compact with variable thickness and diameter.

Fixing the so-obtained membrane at the extremity of an electrochemically inactive tube, one obtains a membrane-electrode with good selectivity for Ag^+ ion. [2]

Based on these preliminary results, it has further on been tested if, and to what extent, a number of factors as : powder granulosity, pressing-pressure and membrane thickness, have an influence upon the electrode function *E*-*p*Ag. At the same time, the electrical resistance of the membranes obtained in various conditions has been evaluated. In the following part, the results of the measurements accomplished in this sense are shown together with their statistical interpretation.

EXPERIMENTAL PART

The Ag_2S powder has been obtained by precipitation with H_2S from an aqueous $AgNO_3$ solution. The precipitate, after washing (free of H_2S) and drying (24 h at 105°) has been finely powdered and washed with CCl_4 (in order to remove the sulphur traces). After eliminating CCl_4 it was powdered again under C_6H_6 in an agate mortar. The dried precipitate (24 h at 105° under stirring) has been sorted by mechanical sieving in five fractions; 1) < 0.05 mm, 2) 0.05–0.125 mm, 3) 0.125–0.16 mm, 4) 0.16–0.25 mm; 5) 0.25–0.5 mm.

The pressing has been carried out in a rigid matrix. The surface of the membranes obtained was of 1 cm.^{2}

The membrane-electrode was made according to the previously reported procedure[1], with the only difference that the potential of the inner face of the membrane has been taken over by a platinum electrode through a mercury layer.

Thus, recording of the electrode function $E-p$Ag corresponds to the measurement of e.m.f. of the following cell:

$$(-)\text{SCE} \left\| \begin{array}{l}\text{bridge of 0.1M KNO}_3\\ \text{agar-agar}\end{array} \right\| \begin{array}{l}\text{test}\\ \text{solution}\end{array} \left| \begin{array}{l}\text{Ag}_2\text{S}\\ \text{membrane}\end{array} \right| \text{Hg, Pt } (+) \tag{1}$$

The test solutions of different pAg have been obtained by diluting an exactly 0.1M $AgNO_3$ solution prepared by weighing.

E.m.f. has been measured with an electronic potentiometer (Radelkis OH 102). The test solution was magnetically stirred. The working temperature was of 25 ± 0.1°.

RESULTS

A. THE ELECTRODE FUNCTION

The influence of granulation of the Ag_2S powder. From the Ag_2S powder fractions obtained membranes have been pressed. The electrode function $E-pAg$ of the corresponding membrane-electrodes has been traced, both at variable ionic strength and at $\mu = 0.1$ M (obtained by adjusting the concentration of the test solutions with KNO_3). The pressing pressure has been of 24 t/cm². Results of the e.m.f. measurements of the cell (1) at $\mu =$ variable and $\mu = 0.1$ M are presented in table 1.

In table 1 are also given the coefficients E_0 and $2.303 \times RT/F$ from the equation of the electrode function (calculated by means of the least square method)

$$E = E_0 - \frac{2.303\ RT}{F} p\text{Ag} \tag{2}$$

corresponding to the studied electrodes, as well as the dispersion of the experimental values referred to the values calculated from the equation of the straight line (2)

$$s^2 = \sum_{1}^{n} \frac{[E_{i\,(\text{exp})} - E_{i\,(\text{calc})}]^2}{n-2} \tag{3}$$

Table 1

Influence of the granulation on the electrode function

The influence of the pressing pressure. From Ag_2S powder corresponding to the fraction 0.05—0.125 membranes have been pressed at different pressures. Results of the $E-p$Ag measurements at $\mu =$ variable and $\mu = 0.1$ M are given in table 2 together with the coefficients corresponding to the equation (2) and dispersion value (3).

The influence of the membrane thickness. From the fraction 1 (< 0.05) membranes of different thickness have been pressed. The pressing pressure was the same in all of the cases (24 t/cm^2). Results of the e.m.f. measurements of the cell (1), at $\mu =$ variable and $\mu = 0.1$ M, together with the coefficient values from the equation (2) and with the value of the expression (3) are given in table 3.

Experimental results presented in tables 1—3 have been submitted to a statistical analysis in order to establish if the factors examined affect the behaviour of the electrode or not. The analysis included the statistical testing of the identity of two straight lines, [3] chosen from the same group of experiments such that to seem to be, at the first sight, the most different. If an insignificant difference is observed, this conclusion will be simplicitly extended upon the whole group of experiments. Further on, a calculation example is given corresponding to the data tabulated in table 1 (columns 1, 3, 5, 7 and 9).

In the first place, it was tested with the aid of the bilateral F criterion, if the most different regressional dispersions (s_5^2 and s_4^2, defined

1.0	487.0	504.0	477.0	483.0	476.0	480.0	473.0	480.0	506.0	510.0
0.0	534.0	—	525.0	—	523.2	—	525.0	—	552.0	—
E_0	543.4	551.1	535.4	544.5	535.4	536.0	524.2	538.0	563.7	567.3
$2.302\frac{RT}{F}$	58.8	59.1	58.7	61.3	60.4	60.1	60.2	60.0	59.8	60.3
s^2	83.6	742.3	73.0	55.7	83.0	156.0	78.0	115.0	90.6	152.0

by the equation (3), are significantly different or not. Since

$$F_{\text{calc}} = \frac{s_5^2}{s_4^2} = 2.68 < F_{\text{tab}\ [\alpha = 0.02\ (5.5)]} = 11.00 \tag{4}$$

it follows that the two most different regressional dispersions do not differ significantly. That is why, with the aid of the equation

$$\overline{s}^2 = \frac{(n_3 - 2)\, s_3^2 + (n_5 - 2)\, s_5^2}{n_3 + n_5 - 4} \tag{5}$$

(where $n_3 = n_5 = 7$ stand for the number of experimental points corresponding to the two straight lines), the weighted mean dispersion has been calculated for the straight lines which have the most different slopes (table 1, columns 5, 9).

Using this weighted mean dispersion ($\overline{s}^2 = 62.3$) the dispersion of the difference of the two slopes from equation (2) has been evaluated

$$s^2_{b_3 - b_5} = \overline{s}^2 \left[\frac{1}{\sum\limits_1^n x_{3i}^2 - n_3 \overline{x}_3^2} + \frac{1}{\sum\limits_1^n x_{5i}^2 - n_5 \overline{x}_5^2} \right] \tag{6}$$

Table 3

Influence of the membrane thickness on the electrode function

$2.302\ \frac{RT}{F}$	58.8	62.1	58.6	60.6	58.1	60.0	57.5	60.3	58.0	59.5	57.7	59.0	57.4	59.4
s^2	148.5	81.5	143.7	56.5	130.7	39.0	172.6	28.0	79.3	42.5	158.2	50.0	154.6	47.5

where: $x_{3_i}^2$ and $x_{5_i}^2$ stand for the squares of pAg values in table 1, columns 5 and 9, respectively; $-\overline{x}_3^2$ and $\overline{x}_5^2$ stand for the squares of the mean pAg values in table 1 columns 5 and 9, respectively.

With the aid of these values ($s^2_{\mathrm{b_3-b_5}} = 4.45$) the value

$$t_{\mathrm{calc}\ (b_3-b_5)} = \frac{b_3 - b_5}{s_{b_3-b_3}} = 0.43 < t_{\mathrm{tab}\ [\alpha = 0{,}02;\ K = 10]} = 3.17 \tag{7}$$

Since the variable "t"$_{\mathrm{calc}}$ < "t"$_{\mathrm{tab}}$ it results that the deviation from the parallelism of the two straight lines is statistically insignificant.

In order to prove the identity of the two straight lines it was observed that

$$\overline{x}_3 = \overline{x}_5 = 3.00 \tag{8}$$

where: $\overline{x}_3$, $\overline{x}_5$ stand for the mean values of pAg in table 1, columns 5 and 9, respectively. That is why, in order to establish the identity of the two straight lines, it would be necessary and sufficient that also

$$\overline{E}_3 \equiv \text{statistically } \overline{E}_5 \tag{9}$$

where $\overline{E}_3$ and $\overline{E}_5$ stand for the mean value of E in table 1, columns 5 and 9, respectively.

By using the bilateral "t" criterion, the following relation has been obtained, indeed.

$$t_{\mathrm{calc}\ (\overline{E}_3\ -\ \overline{E}_5)} = 1.04 < t_{\mathrm{tab}\ [\alpha\ =\ 0{,}02;\ \mathrm{K}\ =\ 12]} = 3.06 \tag{10}$$

consequently, the two straight lines are statistically identical.

B. ELECTRIC CONDUCTIVITY

The electric conductivity of the membranes obtained has been measured by means of the connection given in fig. 1, using a Radelkis OK 102 type conductometer (*c*).

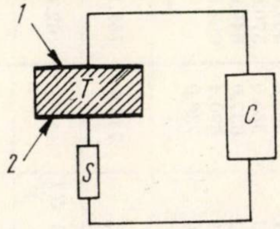

Fig. 1. — Schematic diagram of the working device for conductivity measurements at room temperature.

1,2 — Pt contacts (plates); *T* — tablet; *S* — spring; *C* — conductivity meter;

In order to realize reproducible measurements, it was necessary to assure firstly a constant pressing force of the contacts on the surface of the pellet. Therefore, the spring (*R*) which is the support of the mobile contact (2) was always compressed to a constant length. Meanwhile, in order to eliminate the influence of the membrane thickness upon the conductivity values measured, the specific conductivity has been calculated by referring the measured values to the membrane thickness (these membranes have a surface of 1 cm^2). In table 4 the mean results of three conductivity measurements ($t=25°$) are presented for each membrane obtained in different conditions.

Table 4

Influence of the granulation and pressing pressure on the membrane conductivity

0.25 −0.50	3	34	21.8± 5.5

* dubious experimental values.

Further on, conductivity measurements have been performed at different temperatures. Previously, the thermogram of the Ag_2S powder used has been recorded (fig. 2).

From the thermogram, the possibility of performing measurements in the 50−530° interval has been established. Practically, measurements have been carried out in the 50−190° interval using the connection given in fig. 3. Data obtained are shown in fig. 4. By means of the least square method the equation of the $\sigma(\Omega^{-1}\ \mathrm{cm}^{-1})$ vs T(K) dependence has been calculated.

$$\sigma = 580 \times e^{-4.58 \times 10^3/T}$$

and $E^{\neq} = 0.43$ eV.

DISCUSSION AND CONCLUSIONS

The electrode function. The experimental data collected and their statistical interpretation have proved that neither the granulosity and the thickness of the membrane, nor the pressing pressure have any influence upon the electrode function, certainly, in the region investigated by us. Evidently in elaboration of a membrane with optimal properties, one must take into account and other points of view too, such as economicity, mechanical resistance and so on.

Electric resistance. The values in table 4 indicate also the significant independence of the conductivity values from the obtaining conditions of the membrane (granulosity and pressure). However, it must be noticed that the conductivity values characteristic for the Ag_2S powder compacts

($20 - 50 \times 10^{-3}\ \Omega^{-1}\ cm^{-1}$ on an average) are very small as compared to the Ag_2S crystals $500-800\ \Omega^{-1}\ cm^{-1}$.

The temperature dependence of the conductivity obeys an increasing exponential law, proving, in this way, the mixed character of the conductivity of the Ag_2S powder compacts.

In conclusion, the Ag_2S powder compacts, obtained at pressures between 16–40 t/cm^2, allow Ag^+ -selective membrane-electrodes, with good electrochemical properties, to be obtained.

PAPER THERMOCHROMATOGRAPHY. XVII *
THE SEPARATION OF LEUCINE AND ISOLEUCINE IN TEMPERATURE GRADIENT

C. LITEANU and A. CONSTANTINESCU

"Babeş-Bolyai" University, str. Arany Janos, 11, Cluj, Military Academy, Şos. Panduri nr. 68–70, Bucharest, Romania

Received March 21, 1972

The separation of leucine from isoleucine in temperature gradient on continuous strip chromatograms and on chromatograms with baffles was studied. The growing effect of the chromatographic column length was determined in temperature gradient conditions for both forms of the chromatograms used. In the case of the chromatogram with baffles a greater increase of the separation effect of the temperature gradient was observed ; this favours the separation of the two amino acids which in the conditions of the isothermal chromatography have very close R_f values.

The separation of leucine and isoleucine from complex mixtures cannot be achieved by ascending and descending chromatography with different solvent systems, [1-5] including Mathias isothermic chromatography. [6] The papers published by one of the authors have demonstrated the possibility of chromatographic separation of some anorganic and organic compounds having very close R_f values, by using the temperature gradient. [7-17] Therefore using the solvent system n-butanol + acetic acid + water (4 : 1 : 5 v/v) we aimed to separate leucine and isoleucine by applying the temperature gradient process to a variant of Mathias chromatogram, worked out by us.

With this end in view, the chromatographic paper has two baffles coupled in series, continued by an ascending chromatographic migration band (fig. 1).

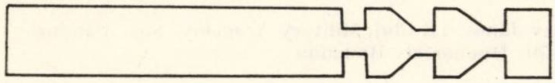

Fig. 1. – Paper chromatogram with baffles.

The chromatographic chamber used is described in a previous paper [13] and the working techniques are the same as in the above mentioned papers. We have first used isothermal chromatography on a paper provided with the two baffles, after which increasing temperature differences between the lower and upper parts of the paper (temperature gradient) were applied, until a satisfactory separation was obtained, the spots of the two amino-acids becoming tangent.

The behaviour of leucine and isoleucine on continuous paper chromatographic strips without baffles was studied concomitantly both isothermically and in temperature gradient, with the same Δt values and the same working time. The data obtained are summarized in tables 1 and 2.

For $\Delta t = 40°$ (t. grad $= 5.88°/\text{cm}$) the separation of leucine and isoleucine can be taken into consideration for both chromatogramic forms.

The optimum estimation criterion for the efficiency of chromatographic separation obtained is the comparison of the "growing of the chromatographic column length" effect in temperature gradient conditions, which can be calculated by means of the Liteanu & Gocan [14] relation

$$(R_f)_{t.\text{grad}} = (R_f)_{\text{isoth}} \times \frac{V + \Delta V}{V} \tag{1}$$

where V is the volume of the mobile phase and ΔV the additional volume of eluent which leaves the chromatographic column owing to the unsaturated atmosphere and its condensation on the eluent surface in the beaker.

By substituting the data in table 1 for t. grad $= 5.88°/\text{cm}$ in relation (1), one obtains :

a) for a paper chromatogram with baffles :

$$0.04 = 0.01 \times \frac{V + \Delta V}{V}$$

or $0.01\ \Delta V = 0.03$ V ; i.e. $\Delta V = 3$ V and because $V = lA_M$ (A_M is the mobile phase section and l is the startfront eluent distance), it results that : $\Delta l = 3l$ i.e. $\Delta l = 3 \times 6.8 = 20.4$ cm.

b) for the paper chromatogram without baffles:

$$0.03 = 0.01 \times \frac{V + \Delta V}{V}$$

was obtained, and, finally $\Delta V = 2V$, i.e. $\Delta l = 2l = 2 \times 6.9 = 13.8$ cm.

The paper chromatogram with baffles increases even more the separation effect of the temperature gradient favouring the separation of these two amino-acids, which in isothermal conditions have very close R_f values.

VERIFICATION OF THE GOCAN-LITEANU RELATION

Gocan and Liteanu [15] have established the following relation between the R_f and the temperature gradient in partition chromatography, on verified paper and on cellulose thin layer [16-17]

$$R_f = \frac{1}{1 + \alpha_0 k_0 - \frac{\alpha_0 k_0}{\text{grad}.l.t.}\,\text{grad}.t.} = \frac{1}{1 + \alpha_0 k_0\left(1 - \frac{\text{grad}.t}{\text{grad}.l.t.}\right)} \qquad (2)$$

where grad. t. l. is the temperature gradient for $R_f = 1$, and $\alpha_0 k_0$ has the same significance as the product αk of the fundamental equation [18] for partition chromatography, i.e. for grad. $t = 0$

$$R_f = \frac{1}{1 + \alpha k} \qquad (3)$$

We intended to verify the validity of relation (2) and, by applying the temperature gradient to the new variant of the chromatogram form used by us.

The data in table 2 were obtained by using, as already shown, the system: n-butanol + acetic acid + water (4 : 1 : 5 v/v) as eluent, in isothermal conditions and afterwards in temperature gradient on paper.

In fig. 2 is represented the variation of R_f values with the temperature gradient and in fig. 3 the values of the αk product depending on the temperature gradient.

One can notice (fig. 2) that the R_f values increase with the temperature gradient and the liniarity of αk values increasing with the gradient (fig. 3) proves the validity of relation (2) even if the open chromatographic column, having the form represented in fig. 1, has been used.

---

[18] R. Consden, A. H. Gordon and A. J. P. Martin, *Biochem. J.*, **38**, 224 (1944).

The value of the limiting temperature gradient could not be experimentally determined as it requires high temperatures at the upper part of the chromatographic chamber.

For leucine *t. l.* grad = 21.5 and for isoleucine *t. l.* grad = 42 are obtained graphically.

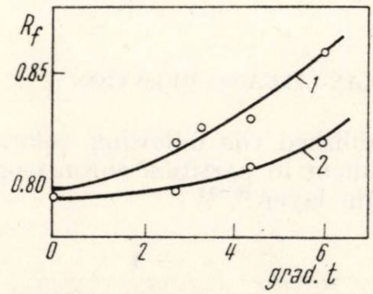

Fig. 2. — Variation of R_f values with the temperature gradient : *1*, leucine ; *2*, isoleucine.

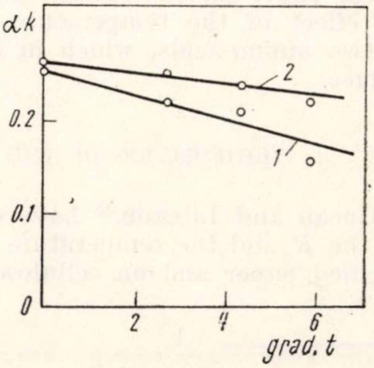

Fig. 3. — The values of the αk product depending on the temperature gradient : *1*, leucine ; *2*, isoleucine.

CONCLUSIONS

By combining the temperature gradient with an open (paper) chromatographic column provided with two baffles at the lower part, leucine could be separated from isoleucine. It was meanwhile proved that the baffles increase the positive effect of the temperature gradient in the separation of these amino-acids.

LE COMPORTEMENT DES IONS INORGANIQUES EN CHROMATOGRAPHIE SUR PAPIER AVEC SOLVANTS À BASE D'ALCOOLS – ACIDES

TIBERIU NĂȘCUȚIU
Institut de physique atomique, B.P. 35, Bucarest, Roumanie

Reçu le 30 juin 1972

On a étudié le comportement d'environ 60 ions inorganiques en solvants d'alcools et d'acide chlorhydrique 1–10N (1 : 1), d'alcools – acide nitrique ou d'alcools – HF 40 % – HCl 6N (en différentes proportions), pour établir les possibilités de séparation. Dans les discussions l'ordre des ions pris en considération est celui de leur disposition dans le système périodique des éléments.

Une série de travaux, publiés par nous ces dernières années, portent sur l'étude de l'efficience de la séparation d'un nombre accru d'ions inorganiques (environ 60), en utilisant les mélanges de solvants : alcools et acide chlorhydrique, alcools et acide nitrique ou alcools, acide hydrofluorique et acide chlorhydrique, en diverses proportions et concentrations. Ces études indiquent tant les solvants donnant la répartition la plus uniforme des ions inorganiques sur l'entier chromatogramme, que le comportement des ions respectifs, en mélange de solvants : alcools et acides. Sur ce dernier sujet, nous allons faire, en ce qui suit, une discussion de caractère général, en traitant les ions considérés dans l'ordre de leur disposition dans le système périodique des éléments.

Les séparations ont été effectuées en utilisant les solvants suivants :

Alcool méthylique – HCl 1, 2, 4, 6, 8, 10N (1 : 1)

Alcool éthylique – HCl 2, 4, 6, 8, 10N (2 : 1)

Alcool *n*-propylique – HCl 1, 2, 4, 6, 8, 10N (1 : 1)

Alcool *iso*-butylique – HCl 1, 2, 4, 6, 8, 10N (1 : 1)

Alcool tertiaire-butylique – HCl 1, 2, 4, 6, 8, 10N (1 : 1)

Alcool *n*-amylique – HCl 1, 2, 4, 6, 8, 10N (1 : 1)

Alcool *iso*-amylique – HCl 4, 6, 8, 10N (1 : 1)

Alcool tertiaire amylique – HCl 2, 4, 6N (1 : 1)

Alcool benzylique – HCl 10, 12N (4 : 1)

Alcool benzylique — alcool éthylique — HCl 6, 8N (2 : 2 : 1)

Alcool méthylique — HNO_3 — 1, 2, 4, 6, 8, 10N (2 : 1)

Alcool éthylique — HNO_3 — 2, 4, 6N (2 : 1)

Alcool éthylique — HF 40% — HCl 6N (75 : 5 : 20)

Alcool éthylique — HF 40% — HCl 6N (95 : 2 : 5)

Alcool *iso*-propylique — HF 40% — HCl 6N (75 : 5 : 20)

Alcool *n*-butylique — HF 40% — HCl 6N (75 : 5 : 20)

Alcool *iso*-amylique — HF 40% — HCl 10N (80 : 5 : 15)

MODE OPÉRATOIRE

Nous avons utilisé des solvants organiques et des acides de différentes provenances, à pureté « pour chromatographie » ou bien « pour analyse ».

Les éléments utilisés ont été dissous en HCl 1N, excepté les substances à tendance d'hydrolyse, qui ont été dissoutes en HCl 6N. Au cas des éléments ayant des isotopes radioactifs à propriétés adéquates, les solutions ont été préparées par dilution des métaux ou des oxydes respectifs, irradiés, au préalable, dans le réacteur nucléaire (v. tableau 1).

Les séparations ont été effectuées par chromatographie ascendante, sur papier Whatman N° 1 (garanti pour chromatographie), dimensions 30 × 30 cm. Le point d'application a été tracé à une distance de 3 cm au-dessus de l'extrémité inférieure de la feuille de papier. Les solutions des ions à séparer ont été déposées sur la feuille de papier à l'aide d'une pipette, à des intervalles de 2—3 cm, les taches initiales ayant les diamètres de 0,5 à 0,8 cm. Dans chaque tache ont été déposés 0,05—35 μg d'élément. Ensuite les chromatogrammes ont été séchés à l'air (environ une heure) ou sous courant d'air chaud et introduits dans les chambres chromatographiques pendant 8—15 heures, afin d'équilibrer l'humidité. Le développement a duré 4—25 heures, fonction de la vitesse de migration du solvant. Lorsque le solvant s'est déplacé à environ 20 cm de la ligne d'application, les chromatogrammes ont été séchés à l'air et soumis aux opérations de révélation avec réactifs de couleur ou par mesures de radiotactivité.

Notre étude comprend presque tous les éléments du système périodique, à l'exception des éléments du groupe des gaz nobles, de certains éléments radioactifs (Fr, Ra, Ac, Pa, Tc, transuraniens) et de quelques éléments produisant des anions (C, N, O, S, B, Si et Ge).

Pour chaque groupe d'éléments ont été effectués 2—3 chromatogrammes, les valeurs R_F, indiquées dans les tableaux étant les moyennes des valeurs obtenues par voie expérimentale. Les erreurs individuelles n'ont pas dépassé de plus de $\pm$ 0,02 les valeurs R_F inscrites dans les tableaux.

RÉSULTATS ET DISCUSSIONS

Li, *Na*, *K*, *Rb*, *Cs*. Dans les solvants d'alcools — HCl ou HNO_3, les métaux alcalins se déplacent sous forme de taches compactes. Les vitesses de migration diminuent au fur et à mesure que la chaîne de l'alcool croît, donc à mesure que décroît le caractère polaire du solvant. C'est pourquoi les meilleures séparations s'obtiennent par les solvants à base d'alcool méthylique.

Li, Na et K ont des vitesses de migration différentes, tandis que chez les métaux alcalins lourds ces vitesses sont presque similaires, les valeurs R_F du rubidium étant plus proches de celles du potassium que de celles du césium. Chez ce groupe la vitesse de migration n'est pas fonction du poids atomique, les valeurs R_F du césium et parfois celles du rubidium dépassant les valeurs R_F du potassium.

Aucun des solvants utilisés ne sépare en totalité les ions de ce groupe d'une manière satisfaisante. Les solvants :

a) alcool méthylique — HCl 4—8N (1 : 1) ;

b) alcool éthylique — HCl 2—4N (2 : 1) ;

c) alcool tertiaire-butylique — HCl 2—4N (1 : 1) séparent les métaux alcalins légers (v. tableau 2), tandis que le solvant à base d'alcool isobutylique – HCl 12N (1 : 1) sépare bien les quantités réduites (< 5 µg) de Cs ($R_F = 0{,}52$) et de Rb^+ ($R_F = 0{,}29$).

Tableau 2

Séparation des métaux alcalins

Solvants	Valeurs R_F					Bibliographie
	Li^+	Na^+	K^+	Rb^+	Ca^+	
Alcool méthylique HCl 4N (1 : 1)	0,86	0,56	0,44	0,47	0,52	[1]
Alcool méthylique HCl 6N (1 : 1)	0,84	0,53	0,40	0,45	0,50	[1]
Alcool éthylique HCl 8N (1 : 1)	0,78	0,47	0,33	0,42	0,47	[1]
Alcool éthylique HCl 2N (2 : 1)	0,67	0,43	0,25	0,26	0,28	[2]
Alcool éthylique HCl 4N (2 : 1)	0,65	0,36	0,20	0,19	0,24	[2]
Alcool tertiaire-butilique HCl 2N (1 : 1)	0,90	0,72	0,59	0,58	0,60	[3]
Alcool tertiaire-butylique HCl 4N (1 : 1)	0,88	0,64	0,52	0,51	0,55	[3]

En solvants fluorhydriques, le lithium développe la plus grande vitesse de migration, mais la tache respective présente une traînée. Les ions des autres métaux alcalins restent sur la ligne de départ. C'est pourquoi les solvants fluorhydriques sont adéquats pour la séparation d'un grand nombre d'éléments d'ions de métaux alcalins. Dans ce but nous recommandons le solvant composé d'alcool iso-propylique – HF 40% – HCl 10N (80 : 5 : 15). [4]

Be, *Mg*, *Ca*, *Sr*, *Ba*. Dans tous les solvants chlorhydriques les métaux de ce groupe se déplacent d'après leur poids atomique, le béryllium ayant les valeurs R_F les plus élevées. Le baryum produit des désagréments à cause du fait que la tache est pourvue d'une traînée s'allongeant à mesure que s'acroît la normalité du HCl.

L'acide nitrique n'imprime pas de différences essentielles dans l'ordre de migration de ces éléments. L'acide fluorhydrique précipite le magnésium, le calcium, le strontium et le baryum sous forme de fluorures et les taches respectives restent sur la ligne d'application ou s'éloignent très peu de celle-ci. La solubilité en HCl des fluorures de magnésium et de calcium imprime à ces ions une tendance de migration, mais les taches respectives présentent une petite proéminence frontale. Le béryllium, qui a une tendance de complexation sous forme de fluorure, se détache nettement des autres éléments de ce groupe.

[4] T. NĂCUŞŢIU, *Rev. Roumaine Chim.*, **12**, 839 (1967).

Nous soulignons le fait, que tant en solvants d'alcool amylique — HCl 4N — qu'en solvants à base d'alcool benzylique, les ions de ce groupe restent sur la ligne d'application, seul le béryllium se déplace, mais avec des valeurs R_F très basses.

Les solvants les plus indiqués dans la séparation de ces éléments sont consignés dans le tableau 3.

Sc, Y, La, lanthanides. Guedes de Carvalho [6] a étudié le comportement des éléments de ce groupe dans des solvants à base d'alcool butylique — HCl et a vérifié l'observation de Lederer concernant la succession des lanthanides sous forme d'une courbe sinusoïdale, plus ou moins accentuée, selon la concentration de l'acide contenu par le solvant. Une étude plus détaillée sur le comportement des éléments de ce groupe a été faite par Maia et Carvalho, [7] qui ont conclut que les solvants étudiés ne permettent pas une séparation satisfaisante de ces éléments.

Nos essais ont suivi surtout la possibilité de séparation des terres rares des autres éléments et non pas leur séparation individuelle.

Le scandium possède la plus grande vitesse de migration en tous les solvants étudiés, étant suivi par l'yttrium et par le lanthane, les valeurs R_F de l'yttrium étant plus proches des valeurs R_F du lanthane que de celles du scandium. Une séparation entre le lanthane et les lanthanides n'a pas été possible avec aucun des solvants essayés.

---

[5] G. Popa et T. Năşcuţiu, *Rev. Roumaine Chim.*, **13**, 315 (1968).

[6] R. A. Guedes de Carvalho, *Analyt. Chim. Acta*, **16**, 555 (1957).

[7] M. O. Maia et R. A. Guedes de Carvalho, *J. Chromatog.*, **8**, 245 (1962).

Pour la séparation du scandium de l'yttrium nous recommandons le solvant d'alcool éthylique – HCl 8N (2 : 1). Les valeurs R_F pour Sc^{3+} et Y^{3+} sont 0,43 respectivement 0,19.

La séparation du Sc, Y et La peut être réalisée avec de l'alcool éthylique – HCl 4N (2 : 1). Les valeurs R_F sont : $Sc^{3+} = 0{,}58$; $Y^{3+} = 0{,}36$; $La^{3+} = 0{,}26$; lanthanides = 0,25–0,33.

En solvants fluor-chlorhydriques, les éléments de ce groupe précipitent sous forme de fluorures et restent sur la ligne d'application.

Ti, Zr, Hf, Th. En mélanges d'alcools supérieurs et d'acide chlorhydrique à normalité élevée, le titane se déplace sous forme d'une tache compacte.

Une bonne séparation du titane des autres éléments s'obtient avec le solvant d'alcool benzylique – HCl 12N (4 : 1). Dans le voisinage de la tache du Ti (R_F = 0,28) sont situés Co (R_F = 0,35), In (R_F = 0,57), Ru (R_F = 0,20), Be (R_F = 0,20) et Li (R_F = 0,17)[8].

En solvants fluorhydriques, le fluorure complexe de titane se déplace avec une vitesse appréciable, se situant dans la partie supérieure ou centrale des chromatogrammes. Dû à ce fait, avec ces solvants le titane peut être séparé de quelques éléments qui l'accompagnent souvent et dont la séparation à l'aide de solvants chlorhydriques n'est pas possible.

Dû à la tendance accentuée d'hydrolyse, le zirconium et le hafnium causent des inconvénients dans la chromatographie sur papier. Dans les solvants étudiés, même à normalités d'acide élevées, les taches des deux éléments ont des traînées plus ou moins accentuées, selon la concentration de l'acide et la nature de l'alcool.

En solvants chlorhydriques, la charge élevée de ces ions diminue la vitesse de migration, les taches respectives étant situées dans le voisinage de la ligne d'application.

La migration des deux éléments sous forme de fluorures complexes est plus acceptable, mais une détermination quantitative ne peut être réalisée, vu qu'une petite quantité de ces éléments reste à la ligne d'application, étant fortement absorbée par le papier filtre pendant le séchage des chromatogrammes avant la révélation. L'utilisation d'un chromatogramme non séché améliore la situation, mais les valeurs R_F sont insuffisamment reproductibles.

Avec aucun des solvants étudiés n'a été obtenue une séparation efficace entre le zirconium et le hafnium.

Le thorium se déplace sous forme d'une tache d'aspect régulier. En solvants chlorhydriques cet élément développe une relative basse vitesse de migration, se situant dans la partie inférieure des chromatogrammes ayant les valeurs R_F proches de celles du hafnium et des lanthanides. La séparation de ces trois groupes d'éléments n'est possible avec aucun des solvants étudiés.

En solvants fluorhydriques, excepté ceux à base d'alcool éthylique, le thorium précipite à la ligne d'application.

---

[8] G. Popa, T. Năşcuţiu et V. Iliescu, *Rev. Roumaine Chim.*, **13**, 447 (1968).

V, *Nb*, *Ta*. Dans tous les solvants étudiés, le vanadium se déplace sous forme de tache compacte. Par contre, dans les solvants chlorhydriques et nitriques, le niobium et le tantale précipitent sur la ligne d'application, les taches respectives ayant une proéminence frontale. C'est pourquoi les valeurs R_F des deux éléments n'ont pas été déterminées.

La tendance de complexation sous forme de fluorures rend meilleur le comportement chromatographique de ces éléments, vu qu'en solvants fluorhydriques le niobium et le tantale se déplacent lorsque les valeurs R_F sont élevées, tandis que le vanadium lorsque ces valeurs sont basses ou moyennes.

La séparation des trois éléments peut être réalisée avec les solvants indiqués dans le tableau 4.

Tableau 4

Séparation de V^V, Ta^V et Nb^V

Solvants	Valeurs R_F			Bibliographie
	V^V	Ta^V	Nb^V	
Alcool *n*-butylique HF 40%–HCl 6N (75 : 5 : 20)	0,15	0,89	0,60	[4]
Alcool iso-amylique HF 40%–HCl 10N (80 : 5 : 15)	0,06	0,32	0,83	[4]

Des séparations exceptionnelles, tant entre le niobium et le tantale, qu'entre ces éléments et le hafnium (zirconium) ont été obtenues avec le solvant d'alcool iso-butylique – HF 40% – acide oxalique ou tartrique 0,5N (35 : 2 : 3).[9]

Cr, *Mo*, *W*, *U*. Dû à la réduction des ions CrO_4^{2-} ou $Cr_2O_7^{2-}$ à Cr^{3+} en solvants chlorhydriques, les taches respectives sont munies d'une traînée ou d'une proéminence frontale. C'est pourquoi nous avons étudié seulement le comportement des ions Cr^{3+}.

En milieu d'acide chlorhydrique ou nitrique, le tungstène précipite sous forme d'acide tungsténique et reste à la ligne d'application. Les études à ^{187}W ont montré que les taches respectives ont des proéminences frontales qui s'allongent simultanément à l'augmentation de la normalité de l'acide du solvant. Cela explique pourquoi le tungstène empêche la séparation des éléments ayant des valeurs R_F basses ou moyennes.

En solvants fluor-chlorhydriques le tungstène manifeste une tendance de migration. Les valeurs R_F résultent aussi bien du rapport entre la concentration de l'acide fluorhydrique et celle de l'acide chlorhydrique, que de la nature de l'alcool.

La séparation des trois éléments peut être réalisée avec un grand nombre de solvants chlorhydriques, à condition que l'acide chlorhydrique ait une concentration de 1–2N.

Mn, *Tc*, *Re*. Les ions MnO_4^- sont réduits en milieu chlorhydrique à des valeurs inférieures ; de la sorte, le comportement de cet élément a dû être étudié sous forme de Mn^{2+}.

La migration du technétium n'a pas été étudiée ; le rhénium se trouvait dans la solution sous forme d'ion ReO_4^-.

---

[9] T. Năşcuţiu et A. Grigorovici, *Rev. Roumaine Chim.*, **10**, 449 (1965).

Vu que les ions Mn^{2+} manifestent une faible tendance de complexation, les valeurs R_F sont remarquablement plus réduites que celles des ions ReO_4^-, ce fait étant plus accentué lors de la diminution du caractère polaire de l'alcool et de l'augmentation de la concentration de l'acide du solvant.

Fe, Co, Ni. Les éléments de ce groupe se déplacent dans l'ordre : $Fe^{3+} > Co^{2+} > Ni^{2+}$, leurs taches étant assez uniformes.

En HCl à normalités réduites, les valeurs R_F du cobalt et du nickel sont proches, tandis qu'à des normalités élevées, la stabilité du chlorure complexe de nickel est réduite et, par conséquent, l'on obtient des séparations assez bonnes. Le tableau 5 indique quatre solvants adéquats pour séparer le cobalt du nickel.

Tableau 5

Séparation de Co^{2+} et Ni^{2+}

Solvants	Valeurs R_F		Bibliographie
	Co^{2+}	Ni^{2+}	
Alcool *n*-propylique–HCl 10N (1 : 1)	0,45	0,26	5
Alcool *n*-amylique–HCl 10N (1 : 1)	0,36	0,21	10
Alcool iso-amylique–HCl 8N (1 : 1)	0,40	0,17	10
Alcool iso-amylique–HCl 10N (1 : 1)	0,57	0,27	10

Le nombre des solvants en état de séparer les trois éléments de ce groupe est plus réduit (v. le tableau 6).

Tableau 6

Séparation de Fe^{3+}, Co^{2+}, et Ni^{2+}

Solvants	Valeurs R_F			Bibliographie
	Fe^{3+}	Co^{2+}	Ni^{2+}	
Alcool iso-butylique HCl 12N (1 : 1)	1	0,60	0,25	11
Alcool *n*-amylique HCl 10N (1 : 1)	0,76	0,37	0,21	10
Alcool benzylique–HCl 12N (4 : 1)	1	0,36	0,05	8

Les métaux platiniques. Pour préparer les solutions nécessaires à la séparation, nous avons utilisé les substances suivantes : $K_2[RuCl_6]$, $(NH_4)_3[RhCl_6]\cdot 3H_2O$, $PdCl_2$, OsO_4, Ir, $K_2[PtCl_4]$ et $H_2[PtCl_6]\cdot xH_2O$.

Après l'irradiation dans le réacteur nucléaire, OsO_4 a été dissous en NaOH, évaporé presque à sec et redissous en HCl 6N. Les réactions qui ont eu lieu peuvent être formulées comme suit :

---

[10] T. NĂŞCUŢIU et V. ILIESCU, *Rev. Roumaine Chim.*, **12**, 853 (1967).

[11] T. NĂŞCUŢIU, *Studii şi Cercetări Chim. Acad. Bucureşti*, **9**, 719 (1961).

$$OsO_4 + 2NaOH = Na_2[OsO_4(OH)_2]$$

$$Na_2[OsO_4(OH)_2] + 6HCl = Na_2[OsO_2Cl_4] + H_2O$$

Pendant la migration Os (VI) est réduit à Os (IV)

$$[OsO_2Cl_4]^{2-} + 4H^+ + 4Cl^- = [OsCl_6]^{2-} + Cl_2 + 2H_2O$$

L'irridium métallique a été solubilisé par fusion avec un mélange de NaOH et $NaNO_2$. En reprenant la fusion, on obtient un mélange de chlorures complexes de Ir (III) et Ir (IV).

Les solvants à base d'alcools inférieurs déplacent les ions de ce groupe dans la partie supérieure des chromatogrammes et aucune séparation convenable ne peut avoir lieu. De plus, les taches sont allongées ou bien munies de traînées. La diminution de la polarité de l'alcool mène à la formation de taches plus uniformes et à des séparations de paires ou de groupes de trois de ces éléments. Quelques ions de ce groupe, par exemple Rh^{IV}, Os^{VI}, Pt^{IV}, etc., forment des taches doubles, soit à cause de la formation d'espèces complexes stables différentes, soit dû à l'action réductrice de la cellulose. Les meilleures séparations ont été obtenues avec les solvants consignés dans le tableau 7.

Tableau 7

Séparation des métaux platiniques

Solvants	Valeurs R_F							Bibliographie
	Ru^{III}	Rh^{IV}	Pd^{2+}	Os^{IV}	Ir^{IV}	Pt^{II}	Pt^{IV}	
Alcool iso-butylique HCl 8N (1 : 1)	0,31	0,43	0,68	0,69	0,39	1,65	0,75	11
Alcool iso-butylique HCl 12N (1 : 1)	0,25	0,34	0,48	0,56	0,27	0,45	0,53	11
Alcool *n*-amylique HCl 10N (1 : 1)	0,25	0,25	0,47	0,65	—	0,60	0,59	10
Alcool iso-amylique HCl 6N (1 : 1)	0,12	0,11	0,56	0,74	—	0,70	0,70	10

Les solvants nitriques et fluorhydriques ne sont pas adéquats à la séparation des métaux platiniques.

Cu, Ag, Au. Les ions d'argent précipitent sous forme de chlorures et restent à la ligne d'application. A mesure que la normalité de l'acide augmente dû à la formation de chlorures complexes, les taches respectives reçoivent une proéminence frontale. C'est pourquoi nous recommandons la précipitation initiale des ions Ag et l'élimination du précipité par centrifugation.

En solvants nitriques les ions d'argent sont réduits pendant l'équilibrage de l'humidité du chromatogramme avec l'humidité de la chambre chromatographique et deux taches se produisent : l'une reste à la ligne d'application (comme argent métallique) et l'autre se déplace. La réduction des ions d'argent peut être évitée si le temps de saturation ne dépasse pas 8 heures.

L'or est aussi réduit à forme métallique, même en solvants chlorhydriques et peut former des taches doubles. En solvants à acide nitrique cet élément se déplace sous forme de taches allongées ; sa séparation d'autres éléments n'est pas satisfaisante. En solvants à HF—HCl les ions de l'or ont des vitesses de migration élevées et se localisent au front du solvant.

La séparation du cuivre de l'or se réalise le mieux en solvants peu polaires et à HCl concentré. L'or se déplace au front du solvant ou dans sa proximité ; le cuivre se déplace à valeurs R_F moyennes.

Pour la séparation Cu—Ag—Au, nous recommandons le solvant d'alcool iso-amylique — HF 40% — HCl 6N (75 : 5 : 20) ; les valeurs R_F sont les suivantes :

$$Cu^{2+} = 0{,}25,\ Ag^{+} = 0{,}00 :\ [AuCl_4]^{-} = 1{,}00$$

Zn, *Cd*, *Hg*. Les ions Hg^{2+} se déplacent à la vitesse la plus grande. A des normalités basses de l'HCl, ces ions sont suivis par Zn^{2+} et Cd^{2+} et à normalités plus élevées de 6N HCl l'ordre de migration change dans le sens $Hg^{2+} > Cd^{2+} > Zn^{2+}$. Le fait que les ions Hg^{2+} ont des valeurs R_F élevées est dû à la faible dissociation du chlorure mercurique et l'inversion observée aux Cd—Zn est due au caractère complexant plus fortement manifesté par le cadmium.

Les valeurs R_F de ces ions sont suffisamment rapprochées, de telle façon qu'une séparation peut être réalisée seulement avec des solvants ayant la normalité de l'acide chlorhydrique inférieure à 2,5. La décroissance de la normalité diminue considérablement les valeurs R_F du zinc et du cadmium par rapport à celles du mercure.

Le solvant pour la séparation la plus efficace des éléments de ce groupe est composé par :
alcool *n*-amylique — HCl 1N (1 : 1) [10].

Les R_F ont les valeurs suivantes :

$$Hg^{2+} = 0{,}60,\ Zn^{2+} = 0{,}18,\ Cd^{2+} = 0{,}08$$

Al, *Ga*, *In*, *Tl*. La faible tendance de complexation manifestée par Al^{3+} détermine cet ion à se déplacer surtout en solvants à teneur de HCl à normalité élevée et à valeurs R_F basses.

L'indium se déplace à des valeurs R_F moyennes et Ga^{3+} et Tl^{3+} sont localisés à des valeurs R_F supérieures. Les ions Tl^{3+}, ayant un caractère plus prononcé de complexation que le gallium, la migration des deux derniers éléments est différenciée dans un milieu faiblement chlorhydrique.

En solvants à HNO_3 l'ordre de migration change dans le sens que les ions Tl^{3+} ont la vitesse de migration la plus élevée. La succession aluminium, gallium et indium diffère selon le cas et une séparation efficace entre les trois éléments n'a pu être réalisée. En solvants à HF—HCl, la compétition entre la complexion du gallium sous forme de fluorure ou de chlorure nous permet de distancer cet élément à la valeur R_F désirée. En certains de ces solvants l'aluminium reste à la ligne de départ, la tache respective ayant une proéminence frontale.

Les solvants adéquats à la séparation des éléments de ce groupe sont ceux du tableau 8.

Tableau 8

Séparation de Tl^{3+}, Ga^{3+}, In^{3+}, et Al^{3+}

Solvants	Valeurs R_F				Bibliographie
	Tl^{3+}	Ga^{3+}	In^{3+}	Al^{3+}	
Alcool iso-butylique—HCl 4N(1 : 1)	0,96	0,63	0,44	0,14	11
Alcool *n*-amylique—HCl 4N(1 : 1)	0,98	0,53	0,18	0,01	10
Alcool iso-amylique—HCl 4N(1 : 1)	1,00	0,83	0,20	0,01	10

Alcool iso-propylique—HF 40 % HCl 6N (74 : 5 : 20)	1,00	0,55	0,35	0,00 PF	4

Ge, Sn, Pb. Le comportement du germanium n'a pas été étudié. Les ions Sn^{2+} et Sn^{IV} ne peuvent être séparés par aucun des solvants essayés.

Les ions Pb^{2+} précipitent sous forme de chlorure et restent à la ligne d'application ou se déplacent à des concentrations de HCl plus élevées, sous forme d'une tache allongée, en dérangeant l'identification des ions à R_F basses ou moyennes.

En solvants à teneur en alcool méthylique et HNO_3, les ions de plomb et de stanium se déplacent sous forme de taches assez uniformes, mais ne peuvent être séparés.

Des écarts entre ces ions s'obtiennent en solvants fluorhydriques.

P, As, Sb, Bi. Les trois premiers éléments, en état de valence maximale, se déplacent à des valeurs R_F élevées ; comme suite, leur séparation est difficile. Par contre, le Bi^{3+} se déplace à des valeurs R_F moyennes, ce qui permet la séparation de ses homologues inférieurs.

L'antimoine, dû à sa tendance d'hydrolyse, cause parfois des désagréments, les taches respectives étant pourvues de traînées visibles, surtout lorsqu'on travaille avec de grandes quantités de substance (< 15 µg) et avec des concentrations basses en acide chlorhydrique. En solvants nitriques, l'antimoine se déplace sous forme d'une bande occupant une grande partie du chromatogramme et empêchant de la sorte l'analyse des autres ions.

En solvants chlorhydriques, une séparation efficace des quatre éléments n'a pas été réalisée, mais un écart entre les ions $PO_4{}^{3-}$ et AsO_4^{3-} a été obtenu avec le solvant d'alcool méthylique — HCl 2N (R_F : $PO_4^{3-} = 0,77$; $AsO_4^{3-} = 0,87$). De bonnes séparations entre les ions As^{V}, Sb^{V} et Si^{3+} peuvent être obtenues avec des solvants à base d'alcool benzylique (v. le tableau 9) et entre As^{V} et Sb^{V}, avec des solvants fluorhydriques (v. tableau 10).

Tableau 9

Séparation de As^{V}, Sb^{V} et Bi^{III}

Solvants	Valeurs R_F			Bibliographie
	As^{V}	Sb^{V}	Bi^{III}	
Alcool benzylique – HCl 12N (4 : 1)	0,64	0,83	0,42	8
Alcool benzylique – HCl 10N (4 : 1)	0,57	0,83	0,33	8

Tableau 10

	As^{V}	Sb^{V}	
Alcool éthylique – HF 40%–HCl 6N (75 : 5 : 20)	0,90	0,70	4
Alcool éthylique – HF 40%–HCl 6N (95 : 2 : 5)	0,85	0,60	4
Alcool iso-propylique – HF 40%–HCl 6N (75 : 5 : 20)	0,81	0,32	4
Alcool *n*-butylique – HF 40%–HCl 6N (75 : 5 : 20)	0,75	0,55	4

Se, Te, Po. La séparation des ions SeO_3^{2-} et TeO_3^{2-} peut être obtenue en plusieurs solvants à teneur en HCl ou HNO_3 diluée (v. le tableau 11). L'augmentation de la concentration de l'acide diminue les différenciations entre les valeurs R_F, tandis qu'une augmentation de la proportion d'alcool dans le solvant imprime un écart plus adéquat entre les deux taches.

La séparation du sélénium et du tellure ayant des valences supérieures peut être obtenue avec un nombre réduit de solvants. Le fait est dû à la tendance du Te (VI) de former des iso-polyacides qui se déplacent sous forme de taches allongées.

Pour la séparation du Se^{IV}, Te^{IV}, Se^{VI} et Te^{VI} peuvent être utilisés les solvants groupés dans le tableau 12.

CONCLUSIONS

Les données presentées ci-dessus nous conduisent à l'affirmation que les solvants d'alcool et d'acide chlorhydrique, en différentes normalités et proportions, permettent la séparation d'un grand nombre d'ions inorganiques. Les solvants étudiés ont été utilisés pour la séparation des produits résultés dans différentes réactions nucléaires, tant en vue de l'identification et de la détermination quantitative, qu'en vue d'obtenir des épreuves ayant une pureté radiochimique adéquate aux mesures de constantes radioactives.

Revue Roumaine de Chimie, **18**, *1*, 175–185 (1973)

L'ÉTUDE DU MÉCANISME PHYSICO-CHIMIQUE DE LA SORPTION DES ISOTOPES RADIO-ACTIFS PAR CERTAINES MACROMOLÉCULES INORGANIQUES POLYÉLECTROLYTIQUES. I

LA SORPTION PHYSIQUE ET CHIMIQUE PAR LA DIATOMITE, LA MONTMORILLONITE, LA KIESELGUHR, LE SILICAGEL, LE KAOLIN ET LA CALCITE, DES RADIONUCLÉIDES DES ÉLÉMENTS I, P, Na, Cs, Sr, Ba, Zn, Cu, Co, Mn et Fe

Reçu le 8 février 1972

Les suspensions et les sédiments des bassins de surface ont la capacité de retenir de nombreux isotopes radio-actifs d'une solution aqueuse. On étudie la capacité de sorption des divers composants chimiques des suspensions et des sédiments des bassins de surface, comme la diatomite, la montmorillonite, la kieselguhr, le silicagel (gel de silice), le kaolin et la calcite. Sont utilisés les isotopes radio-actifs des éléments chimiques suivants : I, P, Na, Cs, Sr, Ba, Zn, Cu, Co, Mn et Fe. On étudie aussi l'action éluante de l'eau sur la capacité de rétention des isotopes par ces macromolécules, pour déterminer l'aspect physique ou chimique de sorption des isotopes par les substances chimiques utilisées.

La pollution radio-active du milieu ambiant par les effluents radioactifs est un processus associé à l'élargissement des domaines d'utilisation de l'énergie nucléaire et des isotopes radio-actifs.

Les isotopes radio-actifs dissous peuvent être accumulés par la sorption dans les sédiments et dans les suspensions des eaux naturelles[1-9]. L'équilibre physico-chimique entre les phases solides et les phases

liquides des bassins de surface déterminent le processus d'accumulation des isotopes radio-actifs dissous. Les plus importants composants chimiques des suspensions des eaux naturelles sont, selon diverses publications scientifiques,[2] la calcite (50%), les argiles (28%), la dolomite (10%), le quartz (10%) et les produits organiques (2%). On a considéré que la composition moyenne des sédiments des eaux naturelles diffère de celle des suspensions. Ainsi Wanderer et d'autres considèrent que les sédiments ont la composition suivante[10] : produits organiques (34%), quartz (28%), calcite (18%) et argiles (20%).

En considérant que la bentonite montmorillonitique, la diatomite, la kieselguhr, le silicagel et le kaolin sont les composants chimiques les plus fréquents dans les sédiments et dans les suspensions, nous avons étudié la capacité de sorption des isotopes radio-actifs par ces substances, tenant compte des propriétés d'échangeurs d'ions des substances mentionnées.[11-12] La présente note comprend l'étude de la sorption des isotopes radio-actifs des éléments chimiques I, P, Na, Cs, St, Ba, Zn, Cu, Co, Mn et Fe, ainsi que les conclusions sur la forme physique ou chimique de la rétention des isotopes par les macromolécules inorganiques étudiées.

MÉTHODE DE TRAVAIL

On a utilisé la bentonite montmorillonique ayant la composition : 69,6% SiO_2 ; 17,8% Al_2O_3 ; 2,03% Fe_2O_3 ; 1,4% CaO ; 0,6% Na_2O — K_2O et la diatomite ayant la composition : 73% SiO_2 ; 9,5% Al_2O_3 ; 3,8% Fe_2O_3 ; 1,5% TiO_2 ; 2,5% CaO ; 3,5% MgO ; 1,0% Na_2O ; 1,2% K_2O et 0,2% P_2O_5. Selon les études aux rayons X toutes les bentonites utilisées appartiennent au type montmorillonite calcique.[13] Le silicagel (gel de silice) utilisé, produit Merk, en perles de 2—5 mm, a été séché à 105°C, ayant un contenu maximal de 3% H_2O. La kieselghur (terre silicée) et le kaolin sont aussi des produits commerciaux, purifiés et calcinés. Le marbre a été utilisé sous forme de poudre blanche avec une granulation maximale de 0,3 mm.

La phase solide, après l'imbibition avec de l'eau distillée, a été maintenue en contact permanent pendant 24—48 heures avec la solution radio-active dans des fioles de centrifuge, dans le rapport : 2 g de terres actives et 50 ml de solution radio-active. Après 48 heures, on a séparé la phase liquide par centrifugation pendant 10 mn à 2500 tours/mn et ensuite on a mesuré radiométriquement, par décantation à l'aide de pipettes, l'activité de la phase solide. On a calculé les résultats en pour cent de l'activité retenue par la phase solide. Pour une détermination précise on a aussi mesuré l'activité retenue par le verre des fioles. La radio-activité a été déterminée directement dans les fioles, au moyen d'un compteur (détecteur à scintillations) *gamma* à puits, type NaI (Tl), connecté à l'échelle de comptage F.H. — 49. L'activité *bêta* a été mesurée à l'aide d'un compteur proportionnel, à circulation de CH_4, en géométrie 50%, de type F.H. — 409 A.

Les solutions radio-actives utilisées, ayant l'activité spécifique de l'ordre de 100 pCi/ml à 1 nCi/ml, proviennent des solutions obtenues au réacteur atomique I.F.A. Bucarest et de l'Amersham, initialement concentrées, et diluées dans notre laboratoire. Les isotopes ont été les suivants : ^{131}I, ^{32}P, ^{22}Na, ^{134}Cs, ^{85}Sr, ^{131}Ba, ^{64}Cu, ^{57}Co, ^{54}Mn et ^{59}Fe.

[12] E. V. Egorov et I. D. Novikov, «Deistvie ionizuruischik izluchenii na ionoobmenye materialy», Atomizdat, Moscou, 1965.

Après détermination radiométrique, la phase solide a été lavée avec de l'eau déminéralisée, en réalisant une proportion de 80 ml d'eau par 1 g de terre. Après lavage, la phase solide a été séparée par centrifugation, l'activité retenue étant mesurée encore une fois radiométriquement.

RÉSULTATS

Les résultats concernant la sorption des radionuclides par la bentonite, la diatomite, la kieselguhr, le kaolin et le marbre (la calcite) sont représentés, en pour cent, sur les figures 1–6, et ceux concernant l'influence éluante de l'eau sur la rétention des isotopes radio-actifs par les macromolécules mentionnées dans les figures 7–12. Ces résultats obtenus de l'étude simultanée de 4 échantillons, révèlent des erreurs expérimentales allant de 0,5 à 3,3%, ce qui permet de tirer les conclusions suivantes :

En conditions statiques les isotopes ^{134}Cs, ^{85}Sr, ^{65}Zn, ^{64}Cu, ^{57}Co, ^{54}Mn et ^{69}Fe dissous dans la solution aqueuse sont retenus dans une proportion de 91 à 99% par la bentonite montmorillonitique, tandis que les isotopes ^{22}Na et ^{131}Ba seulement de 40 à 70%. L'isotope ^{32}P est retenu en proportion de 20% et l'isotope ^{131}I de 2 à 5% (fig. 1).

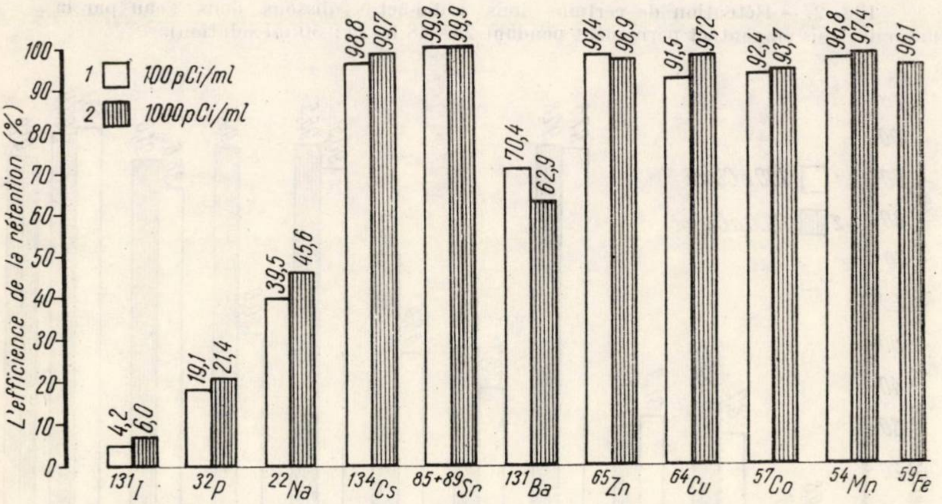

Fig. 1. — Rétention de certains ions radio-actifs dissous dans l'eau, par la montmorillonite mis en contact permanent pendant 24–48 h (2g : 50 ml solution).

Le kieselguhr et le silicagel réagissent de manière différente, vu que le premier retient de 90 à 99% d'isotopes ^{134}Cs, ^{65}Zn, ^{64}Cu, ^{57}Co, ^{54}Mn et ^{59}Fe, le second retenant dans cette proportion seulement le nucléide ^{57}Co. La rétention par la kieselguhr des isotopes ^{131}Ba et ^{64}Cu diffère en fonction de l'influence de la concentration de la solution radio-active. On a aussi remarqué que les isotopes ^{32}P, ^{22}Na, ^{85}Sr et ^{131}Ba sont retenus dans une proportion inférieure à 50% (fig. 3—4).

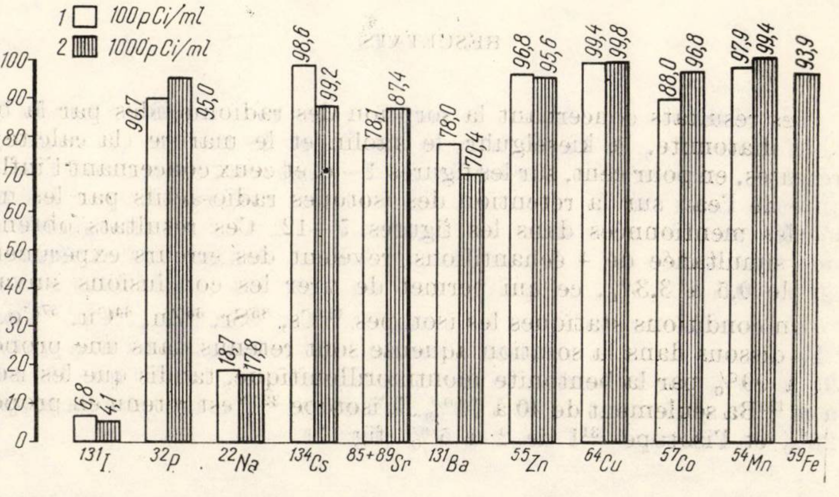

Fig. 2. — Rétention de certains ions radio-actifs dissous dans l'eau par la diatomite mis en contact permanent pendant 24—48 h (2g : 50 ml solution).

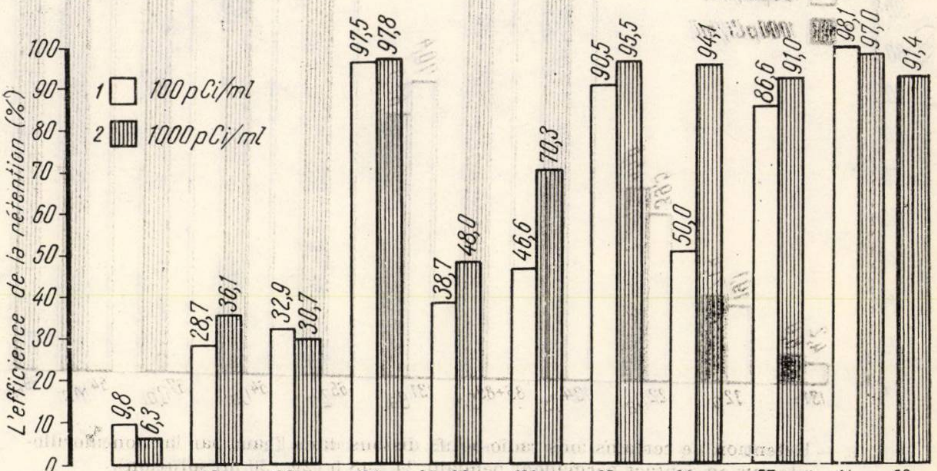

Fig. 3. — Rétention de certains ions radio-actifs dissous dans l'eau par la kieselguhr mis en contact permanent pendant 24—48 h (2 g : 50 ml solution).

Le kaolin présente certaines particularités, retenant les isotopes ^{32}P, ^{134}Cs, ^{65}Zn, ^{64}Cu, ^{57}Co, ^{54}Mn et ^{59}Fe, dans une proportion dépassant 50%, tandis que le nucléide ^{22}Na est retenu à 73% et les nucléides ^{85}Sr et ^{131}Ba

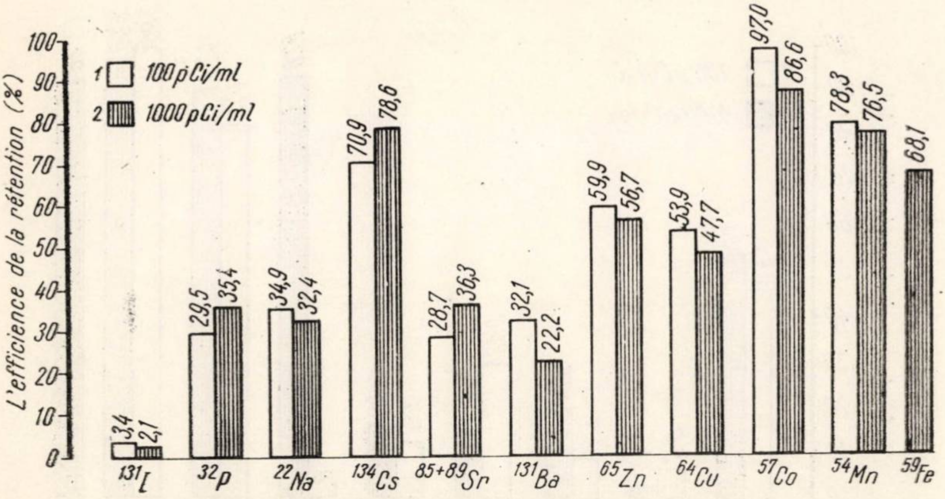

Fig. 4. — Rétention de certains ions radio-actifs dissous dans l'eau par le silicagel mis en contact permanent pendant 24—48 h (2 g : 50 ml solution).

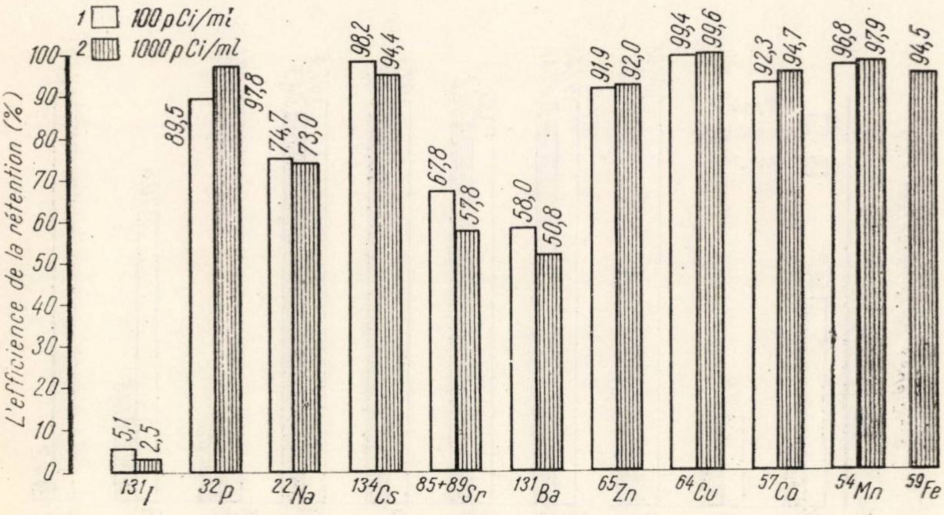

Fig. 5. — Rétention de certains ions radio-actifs dissous dans l'eau, par le kaolin, mis en contact pendant 24—48 h (2 g : 50 ml solution).

sont retenus de 50 à 60% (fig. 5). La calcite du marbre retient jusqu'à 90% les isotopes ^{64}Cu, ^{57}Co, ^{54}Mn et ^{59}Fe et seulement de 45 à 50% le nucléide ^{32}P. Les isotopes ^{22}Na, ^{134}Cs, ^{85}Sr et ^{131}Ba sont retenus dans une proportion inférieure à 30% (fig. 6).

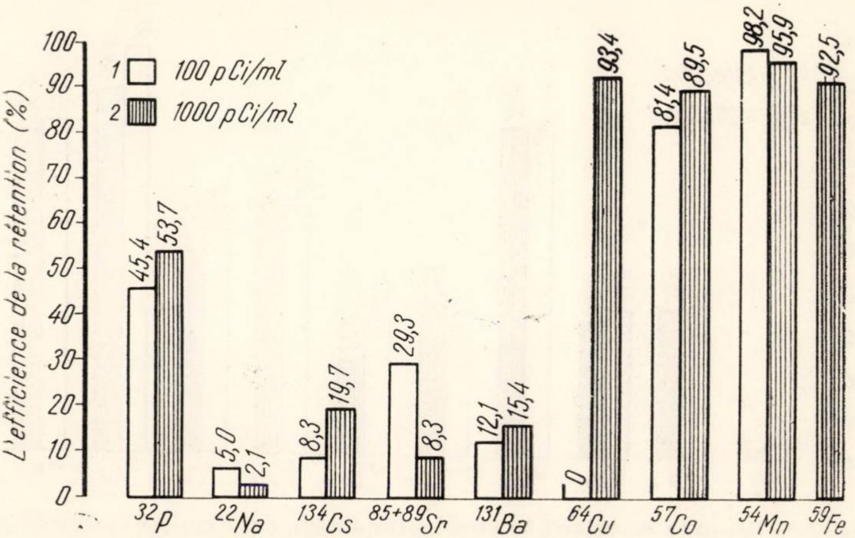

Fig. 6. — Rétention de certains ions radio-actifs, dissous dans l'eau, par le marbre, mis en contact permanent pendant 24—48 h (2 g : 50 ml solution).

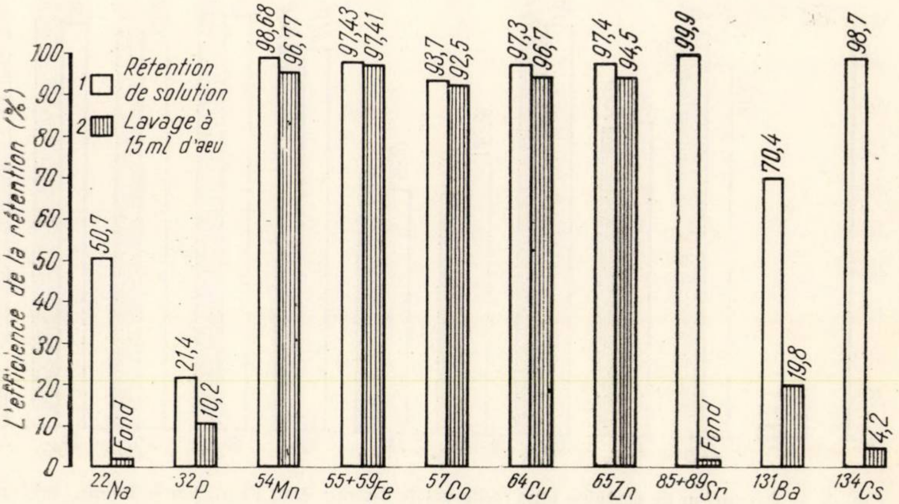

Fig. 7. — Influence sur l'efficience de la rétention des ions radio-actifs par la montmorillonite, après un contact pendant 24—48 h sous l'action éluante de l'eau.

Les résultats représentés sur les figures 7—12 font ressortir dans les conditions statiques l'effet éluant de l'eau sur la rétention des isotopes par les macromolécules inorganiques étudiées.

---

[13] VL. LAMBRINO et GH. FURNICĂ, *Compt. rend. de l'Acad. Bulgare de Sciences*, **22**, 1111 (1969).

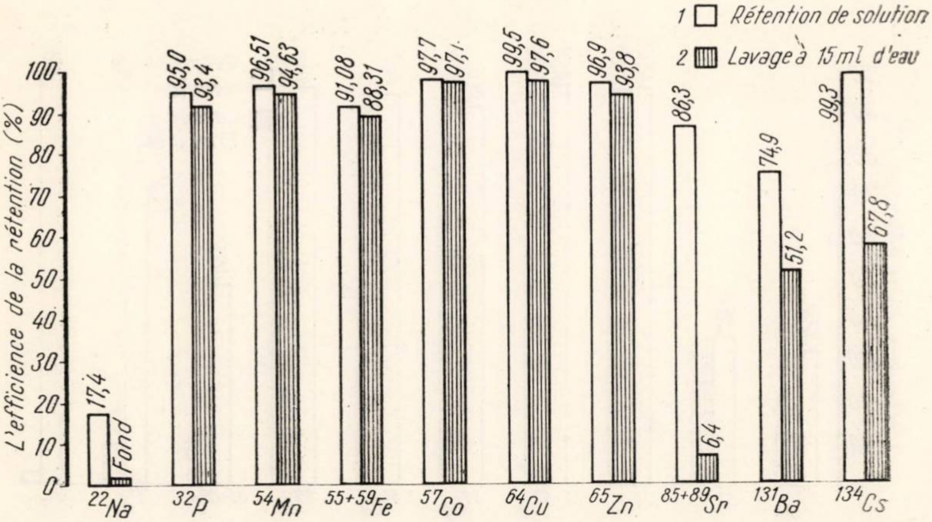

Fig. 8. — Influence sur l'efficience de la rétention des ions radio-actifs par la diatomite, après un contact pendant 24—48 h, sous l'action éluante de l'eau.

On a remarqué au cas de la monmorillonite que les nucléides ^{22}Na, ^{85}Sr et ^{134}Cs sont élués dans une proportion de 90%, le nucléide ^{32}P à 50% et le radionucléide ^{131}Ba dans une proportion dépassant 75% (fig. 7). La diatomite perd par élution 90% de nucléide ^{22}Na, 85% de nucléide ^{85}Sr, plus que 25% de nucléide ^{131}Ba et plus que 40% de nucléide ^{134}Cs (fig. 8). Les radionucléides ^{54}Mn, ^{59}Fe, ^{57}Co, ^{64}Cu et ^{65}Zn retenus par la diatomite et la montmorillonite sont élués seulement dans une proportion de 3 à 7% par l'eau, tandis que ^{32}P, retenu par la diatomite, est élué seulement dans une proportion de 3 à 4%.

La kieselguhr (fig. 9) retient les isotopes ^{54}Mn, ^{59}Fe, ^{57}Co, ^{64}Cu dans une proportion élevée, mais l'élution par l'eau provoque une élimination moyenne de 2 à 14%. On a aussi remarqué que ^{32}P retenu par la kieselguhr dans une proportion de 36% est élué jusqu'à 15%, par lavage avec de l'eau, donc ^{22}Na est élué jusqu'à 20%. Les nucléides ^{65}Zn, ^{85}Sr, ^{131}Ba et ^{134}Cs sont élués dans une grande proportion jusqu'à 40—95%. Le silicagel (fig. 10) perd en petite quantité les nucléides ^{54}Mn, ^{59}Fe, ^{57}Co, ^{64}Cu et ^{65}Zn (1 — 6%), mais l'effet éluant est plus intense pour les isotopes ^{22}Na, ^{32}P, ^{85}Sr, ^{131}Ba et ^{134}Cs.

Les nucléides ^{32}P, ^{54}Mn, ^{59}Fe, ^{57}Co, ^{64}Cu et ^{65}Zn retenus par le kaolin (fig. 11) dans une proportion élevée sont ensuite éliminés en petite quantité par l'effet éluant de l'eau (de 1 à 9%). Les nucléides ^{134}Cs et ^{131}Ba sont élués dans une proportion de 30 à 33%, tandis que les isotopes ^{22}Na et ^{85}Sr sont éliminés par l'eau à 99%. Il est intéressant de mentionner que la calcite du marbre (fig. 12) a retenu des quantités plus élevées de ^{54}Mn,

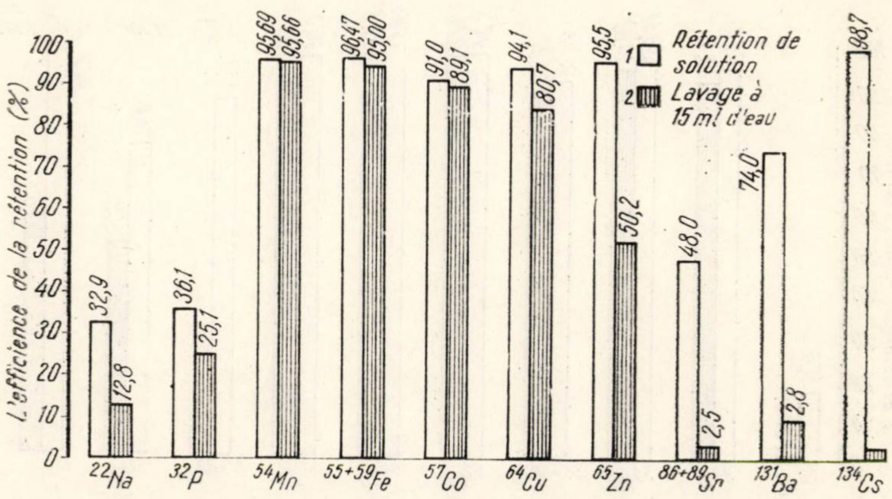

Fig. 9. — Influence sur l'efficience de la rétention des ions radio-actifs par le kieselguhr, après un contact de 24 à 48 h, sous l'action éluante de l'eau.

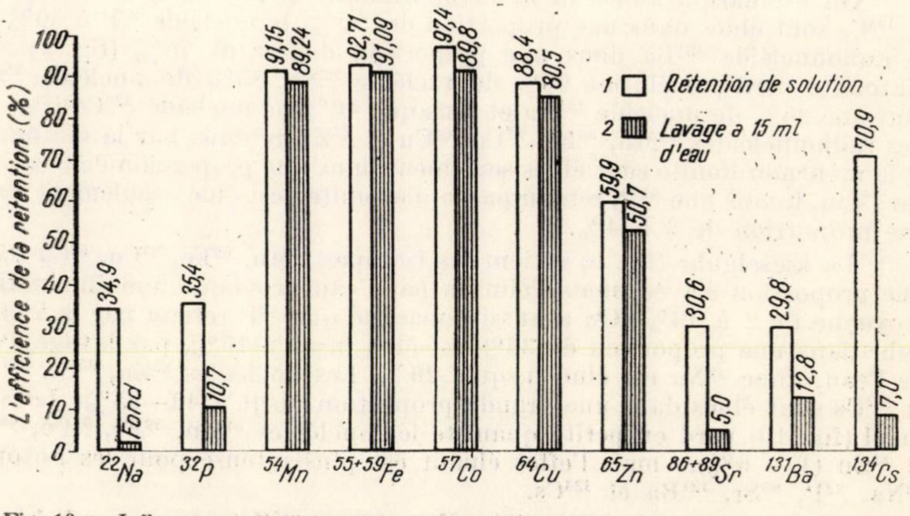

Fig. 10. — Influence sur l'efficience de la rétention des ions radio-actifs par le silicagel, après un contact de 24 à 48 h, sous l'action éluante de l'eau.

^{59}Fe, ^{57}Co et ^{64}Cu, de nucléides qui sont après élués en petites proportions (de 1 à 6%). Le nucléide ^{134}Cs retenu dans une petite proportion est éliminé aussi en petites quantités. Dans le cas des nucléides ^{32}P et ^{131}Ba les quantités retenues par le kaolin sont éluées jusqu'à 50%.

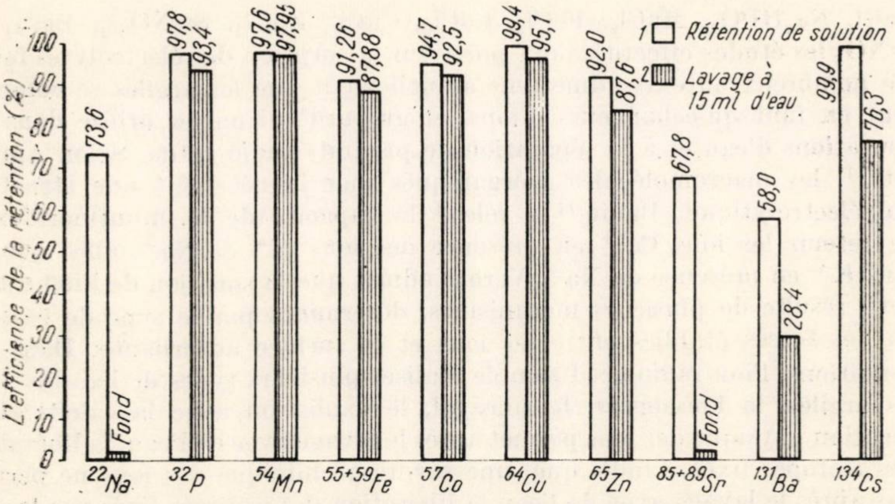

Fig. 11. — Influence sur l'efficience de la rétention des ions radio-actifs par le kaolin, après un contact de 24 à 48 h, sous l'action éluante de l'eau.

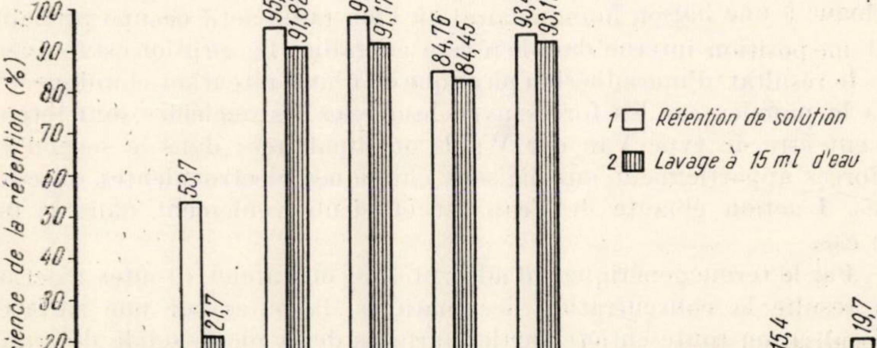

Fig. 12. — Influence sur l'efficience de la rétention des ions radio-actifs par le marbre, après un contact de 24 à 48 h, sous l'action éluante de l'eau.

DISCUSSIONS

Les résultats obtenus révèlent la différence de la capacité de sorption des divers ions radio-actifs par les macromolécules inorganiques étudiées. Compte tenu que toutes les combinaisons chimiques utilisées ont été :

NaCl, Na_2HPO_4, $MnCl_2$, $FeCl_3$, $CoCl_2$, $CuCl_2$, $ZnCl_2$, $Sr(NO_3)_2$, $BaCl_2$ et $CsNO_3$ les études effectuées ont porté sur la sorption des électrolytes forts. De nombreux auteurs admettent actuellement que les argiles se comportent en tant qu'échangeurs d'ions, et aujourd'hui on les utilise dans les épurations d'eau et à la séparation de produits radio-actifs. Selon Amphlett, [11] les macromolécules inorganiques mentionnées ont une structure polyélectrolytique. Banin [14] a relevé la capacité de la montmorillonite de retenir les ions Ca^{2+} en présence des ions K^+ et Na^+, ainsi que les ions K^+ en présence de Na^+. Verot [8] admet que la sorption de l'ion radioactif résulte de plusieurs mécanismes, déterminés par le type de liaisons ou des forces établies entre les ions et la surface adsorbante. Dans ces conditions, l'ion radio-actif semble réaliser plusieurs types de liaisons avec les argiles, la kieselguhr, le silicagel, le kaolin ou avec la calcite. Une sorption physique des ions permet après le lavage avec de l'eau, la libération des isotopes fixés, tandis que, une sorption chimique des ions ne permet pas après le lavage avec de l'eau la libération des isotopes fixés par la surface absorbante. Dans ces conditions, Bittel admet que l'ion radio-actif semble réaliser avec le substratum deux principaux types de liaison [2] : une liaison relativement labile analogue à une liaison hétéropolaire où l'ion radio-actif peut être remplacé par d'autres ions et une autre liaison (analogue à une liaison homopolaire) où l'ion radio-actif occupe probablement une position interne dans le réseau cristallin. La sorption est fréquemment le résultat d'une adhésion physique ou d'une rétention chimique. [15,16] Dans le premier cas les forces avec lesquelles les nucléides sont retenus peuvent être de type Van der Waals ou dipolaires ; dans le second cas ces forces appartiennent aux liaisons chimiques électrovalentes ou covalentes. L'action éluante de l'eau est efficiente seulement dans le premier cas.

Par le terme générique « d'adsorption », on entend « toutes réactions d'où résulte la concentration des matières dissoutes sur une surface ». La localisation toute entière sur les surfaces de la phase solide détermine la sorption « secondaire ». Dans d'autres conditions la sorption devient de type « primaire » pour les mécanismes de réactions impliquant la rétention dans des graines (ou des réseaux cristallins). Par conséquent, on peut admettre que les trois paramètres les plus importants déterminant le comportement d'un système hétérogène envers la sorption d'un constituant ionique d'une solution aqueuse sont les suivants : le pouvoir d'échange (de sorption) ; la constante d'équilibre chimique ou d'échange isotopique et la diffusion.[17-30] Nos résultats montrent que la sorption des ions radio-actifs des éléments Na, Cs, Ba et Sr en contact avec la montmorillonite se déroule dans une proportion de 80 à 90% à l'aide des forces non chimiques. Cette proportion baisse de 30 à 50% en contact avec la diatomite. La kieselguhr retient physiquement ces ions radio-actifs dans une proportion de 10 à 55%, tandis que le kaolin retient chimiquement les radio-ions Cs* et Ba^{2+} dans une proportion de 45 à 75%. La calcite maintient chimiquement l'isotope Cs dans une proportion de 85%, tandis que les isotopes de Ba sont fixés dans une proportion de 50% et l'ion $H_2PO_4^-$ dans une proportion de 45%. Les ions radio-actifs des nucléides du Mn, Fe, Co, Cu et Zn sont retenus chimiquement par la montmorillonite et la diatomite dans une proportion de 85 à 100%.

Les résultats mentionnés permettent de conclure que la sorption des ions radio-actifs d'une solution aqueuse par les macromolécules inorganiques peut être attribuée à la formation des liaisons physiques ou chimiques entre ces deux groupes des substances. La proportion des liaisons physiques ou chimiques formées dépend de la nature chimique des ions et de la structure des groupements chimiques des macromolécules inorganiques. Nos résultats démontrent en même temps la nécessité d'effectuer des études suivies concernant la nature de la liaison chimique entre les divers ions radio-actifs retenus et les macromolécules inorganiques mentionnées.

NOTE POUR LES AUTEURS

La *Revue Roumaine de Chimie* publie des articles en anglais, français, russe, allemand ou espagnol. Les auteurs sont priés d'envoyer des articles, notes, communications et comptes rendus inédits.

Les manuscrits seront dactylographiés à deux intervalles. Les tableaux seront dactylographiés sur feuilles séparées, de même que la légende des figures. Les diagrammes seront tracés à l'encre de Chine sur papier calque. Les tableaux et les figures seront numérotés par des chiffres arabes, en nombre strictement nécessaire. Prière de ne pas inscrire les mêmes données dans les tableaux et les figures. Les formules chimiques seront incluses dans le texte ; en outre, elles seront transcrites sur des feuilles séparées. ELECTRONIC ABSORPTION SPECTRA OF SILVER HALIDES IN PASSING FROM SOLID TO MOLTEN STATE

I. G. MURGULESCU, E. POPA and EUGENIA IVANA

Center of Physical Chemistry
Str. Galaţi 31, Bucharest — 13, Romania

Received September 22, 1972

Electronic absorption spectra of silver halides in passing from solid to molten state were obtained. A bathochromic shift of the absorption band edge with temperature was observed. The observed energy jumps at melting points and bathochromic effect are explained as due to the same structural modification.

1. INTRODUCTION

The resemblance of the ultraviolet absorption spectra of AgCl, AgBr and AgI [1–5] with those of alkali halides is well-known.

The AgCl absorption spectrum in solid state at 20 K is composed of a broad maximum at about 50,000 cm^{-1} and another at 42,000 cm^{-1} (doublet).

The same general characteristics may be noticed for the Ag Br spectrum at 20 K, that is a continuous absorption in the range of 50,000 cm^{-1}, a maximum at 34,500 cm^{-1} and another at 39,000 cm^{-1}.

Similarly, AgI has a continuous absorption in ultraviolet and a maximum at about 23,600 cm^{-1}.

However, in contrast to the alkali halides, silver halides have absorption tails which extend towards longer wavelength. The origin of these long wavelength absorption tails has been a matter of speculation for many studies. [3,5–9]

In the literature, AgCl and AgBr were investigated in the molten state,[10,11] and the influence of the temperature upon the absorption band edge was studied.

This work reports the absorption spectra of AgCl, AgBr, and AgI in passing from solid to molten state.

2. EXPERIMENTAL PART

The absorption measurements were carried out with a "Specord UV-VIS" Carl Zeiss Jena recording spectrophotometer.

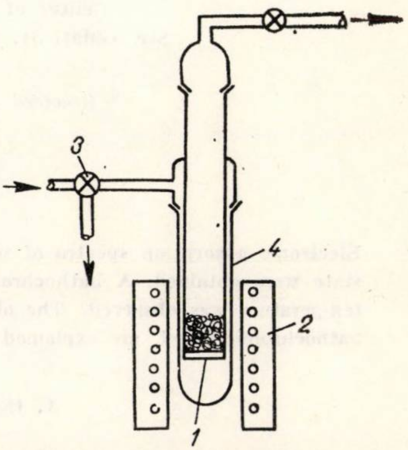

Fig. 2. — Drying and filtering apparatus.

1, Glass frit; *2*, Furnace; *3*, Two way top; *4*, AgX.

The usual cells holder was replaced by a furnace (fig. 1) permitting temperatures up to 700°.

The temperature uniformity inside the furnace has been controlled by two Pt—Pt, Rh thermocouples placed in two different sites.

On account of the very strong absorption of the melt, cells with a thickness of about 10 μ have been used. These were filled and sealed under vacuum.

The silver halides were prepared from diluted solutions of $AgNO_3$, respectively with KCl, KBr and KI previously recrystallized. The silver salts obtained in this way were dried and purified with the installation presented in fig. 2.

An argon stream, previously purified and dried, is passed through a G-3 glass frit, on which the salt is to be found.

The system of purification is composed of a tube of glass filled with metallic copper and two tubes of glass filled respectively with P_2O_5 and silicagel.

The temperature is gradually raised by means of the furnace (fig. 2) in which the lower part of the installation is introduced.

[11] B. R. Sundheim and J. Greenberg, *J. Chem. Phys.*, **28**, 439 (1958).

Near to the melting point and after the melting of the salt, a dried current of HX gas is passed through.

For removing of HX, the installation is washed with argon, 2–3 h after melting. Then the melt is filtered. All the preparing and purifying operations have been performed in darkness, due to the sensitivity of the silver halides to light.

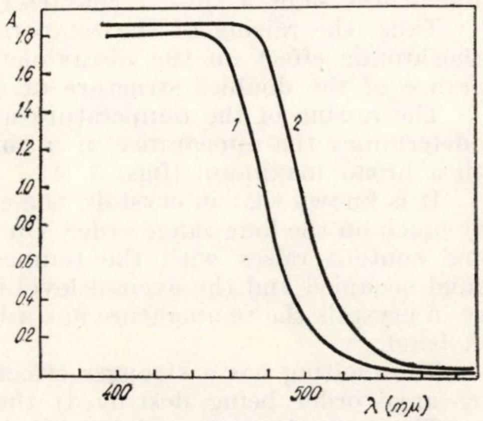

Fig. 4. — Absorption spectrum of AgBr.

1, $t = 425°$ (solid) ; *2*, $t = 470°$ (melt).

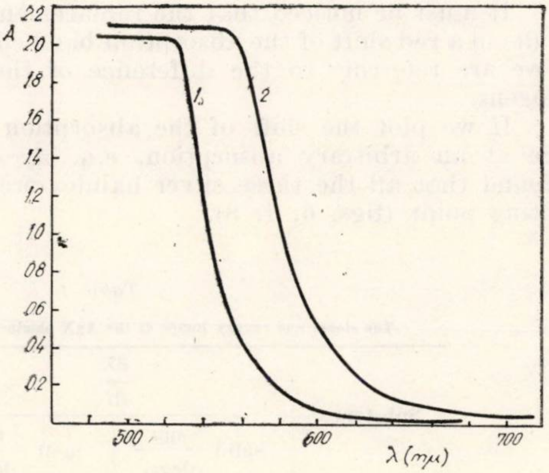

Fig. 5. — Absorption spectrum of AgI.

1, $t = 530°$ (solid) ; *2*, $t = 580°$ (melt).

3. RESULTS AND DISCUSSIONS

The absorption spectra of AgCl, AgBr and AgI are presented in figs. 3, 4 and 5.

After examining the spectra, we found that these present a continuous absorption with a broad maximum at about 380 mμ ($t = 470°$) for AgCl and at about 460 mμ ($t = 470°$) for AgBr.

For AgI we found a very strong absorption between 400—550 mμ without any maximum. The absorption suddenly diminishes at about 555 mμ ($t = 580°$). We can also notice a shift of the edge of the absorption band with the temperature, to low energies, both in the molten and solid state.

The studies on AgX absorption spectra in the solid state at low temperatures show a similar characteristic.

Thus, the raising of the temperature from 20 K to 293 K has a bathochromic effect on the ultraviolet absorption band and the disappearance of the doublet structure of the band.

The raising of the temperature up to the melting point and above it, determines the appearance of a continuous absorption (figs. 3, 4, 5) with a broad maximum (figs. 3, 4).

It is known that in crystals, the energy of the ground state depends very much on the long-range order. On account of the fact that the vibrational content raises with the temperature, the interval between the ground occupied and the excited level is diminished. Thus it is explained why in crystals the temperature has a bathochromic effect on the absorption band.

The melting has a stronger effect upon the fundamental level (the long-range order being destroyed) than upon the excited level.

Thus, the fundamental band being strongly delocalized, the energetic interval between the levels diminishes and the spectrum will occur at longer wavelength.

It must be noticed that the replacement of the Cl^- with Br^- and I^- results in a red shift of the absorption band edge, which is easily explained, if we are referring to the difference of the electronic affinity of the halogens.

If we plot the shift of the absorption band edge (the wavelength edge at an arbitrary absorption, e.q. $A = 1$) against temperature, it is found that all the three silver halides present finite jumps (Δ) at the melting point (figs. 6, 7, 8).

Table 1

The slopes and energy jumps of the AgX obtained from plots no 6, 7, 8

Substance	$\frac{d\lambda}{dt}$ solid $\frac{m\mu}{degr.}$	$\frac{d\lambda}{dt}$ melt $\frac{m\mu}{degr.}$	Δ (cm^{-1})
AgCl	0.363	0.20	982
AgBr	0.28	0.15	825
AgI	0.15	0.11	850

In table 1 the values of these jumps (Δ) and also the slopes $d\lambda/dt$ of the absorption band edge are inserted, both in the solid and molten state (the columns 2, 3).

The slopes of the absorption band edge in the solid state are greater than those in the molten one.

This fact proves that the temperature determines more structural modifications in the solid than in the molten state. The values of these slopes decrease from AgCl to AgI both in solid and molten state and there are small differences between those of the molten state.

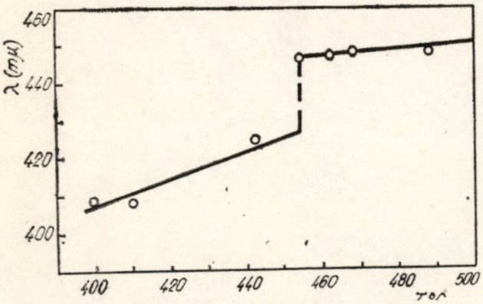

Fig. 6. — Temperature variation of the absorption band edge of AgCl.

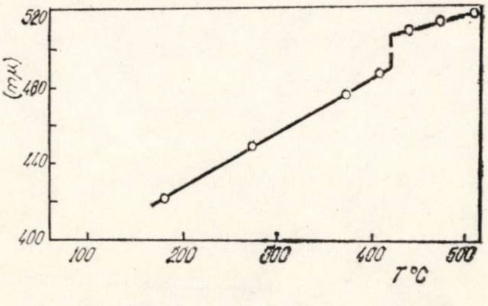

Fig. 7. — Temperature variation of the absorption band edge of AgBr.

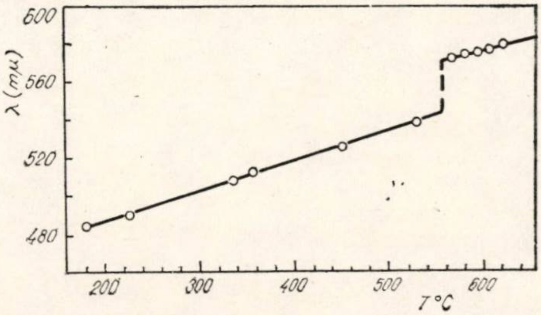

Fig. 8. — Temperature variation of the absorption band edge of AgI.

These results are also in concordance with other physicochemical properties [12-14] of the silver halides in their passing from solid to molten state (the change of the melting volume, the heat of melting etc.).

SOME ASPECTS OF THE COOL FLAME AND LOW-TEMPERATURE IGNITION OF METHANE

ILEANA IOSIF, I. A. SCHNEIDER and C. VOLANSCHI

Centre of Physical Chemistry
Str. Galaţi, 31, Bucharest 13, Romania

Received July 20, 1972

The methane oxidation initiated by nitric acid was investigated in a dynamical system at 557°. The emission spectrum of the cool flame was recorded in order to understand the complex physical and chemical processes which lead to the appearance of the flame phenomenon. By modifying the conditions of the reaction in a series of experiments, the ignition phenomenon was studied.

The slow oxidation of hydrocarbons has been the object of extended experimental and theoretical [1–5] works, which have indicated the existence of two temperature-dependent mechanisms, i.e. high-temperature and low-temperature regions. [6]

The transition between these two temperature regions is frequently associated with the appearance of some interesting effects, such as the negative temperature coefficient, the cool flame and the ignition phenomenon.

The appearance of the "cool flame" was observed as far back as 1924 in a work related to the oxidation of octane. [7] Extending this work to some paraffins, olefines, naphthenes, aldehydes and ethers, [8,9] Prettre noticed the absence of the cool flame in methane and ethane.

However, in 1953 Gray, [10] studying the oxidation of ethane in the 500°–600° temperature range, and somewhat later Vanpée, [11] studying

the oxidation of methane in statical conditions, succeeded to evidence the flame phenomenon in these two first members of the parafinic series too. More detailed studies concerning the phenomenon of cool flame in methane were carried out later[12-14] and these revealed the various factors which influence the phenomenon.

In this work, the emission spectrum of the cool flame was recorded, in order to understand more accurately the complex chemical and physical processes which lead to the flame phenomenon.

EXPERIMENTAL

Tne working technique was similar with that described in an earlier paper.[14] To record the emission spectrum, a Carl-Zeiss Jena spectrograph with glass optics was used.

The dynamical conditions of the reaction permitted to maintain the flame steady as position and intensity, during the 5–7 hr which were necessary to obtain an emission spectrum.

RESULTS AND DISCUSSIONS

The spectrum of the cool flame obtained in the air oxidation reaction of methane, initiated by nitric acid is shown in Fig. 1.

For comparison, in Fig. 2 is shown the spectrum of the cool flame obtained for heptane-air mixture[15] with a quartz Hilger spectrograph.

It can be seen that a correspondence exists between the wavelengths of the bands in these two spectra, on the one hand, and the band wavelengths reported by Emeleus[16] for the cool flame of ether, on the other. The spectrum of the cool flame was first described by Emeleus and later identified by Kondratiev[17] as being the fluorescence spectrum of formaldehyde, the main bands lying in the 3600–4500 Å range.

According to the results of Walsh,[18] the reaction in which the excited formaldehyde is formed must be exothermic to the extent of at least 77 kcal/mol.

Taking this into account, the following radicalic reactions may be proposed, even if their probabilities of taking place are relatively low[6]: $H + H\dot{C}O \rightarrow HCHO^{*}$ (e) electronically excited knowing that the dissociation energy of the C–H band is 87 Kcal.

Since several vibrational states correspond to a given electronic state, it is plausible to admit that the most probable transition is that between the electronically excited state and the first vibrational level

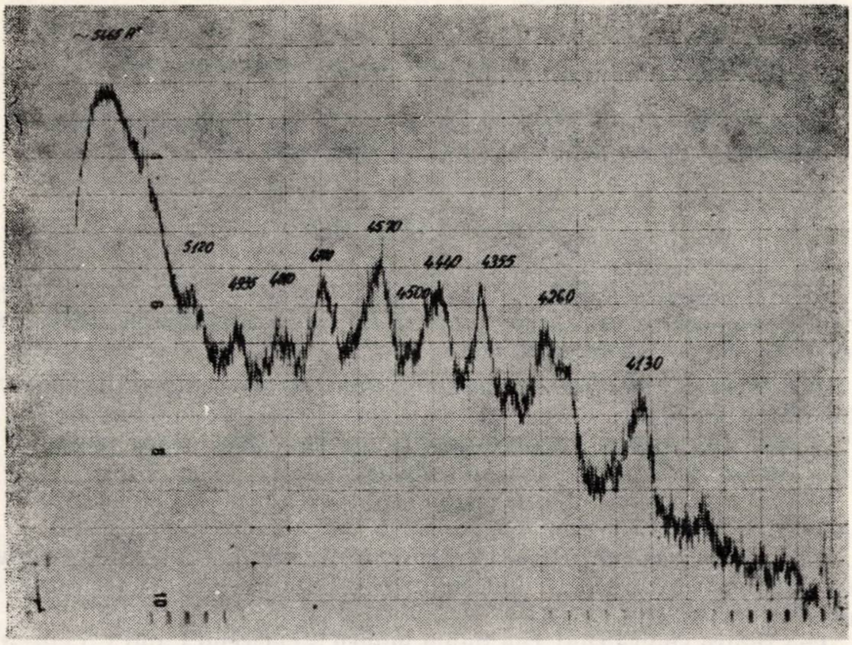

Fig. 1. — Spectrum of the cool flame of methane.

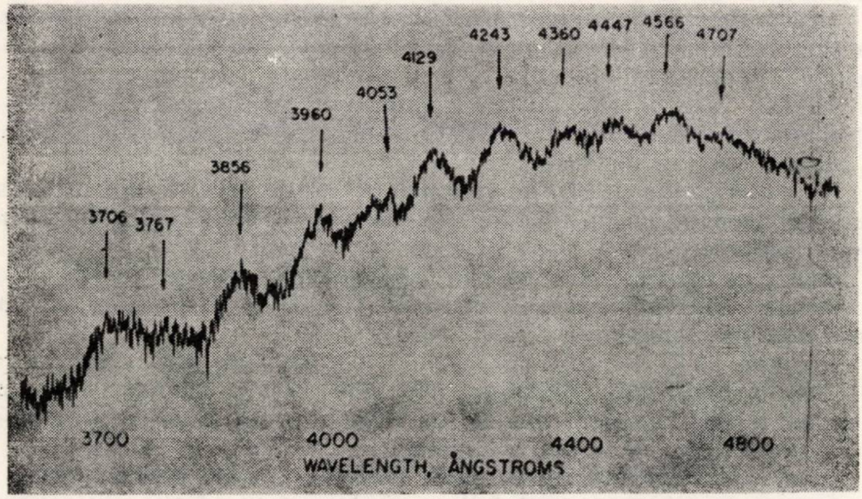

Fig. 2. — Spectrum of the cool flame of n–heptane. 15

of the lower electronic state; this transition is accompanied by light emission:

$$\mathrm{HCHO^*\,(e)} \xrightarrow{h\nu} \mathrm{HCHO^*\,(v)}\ \text{vibrationally excited.}$$

Several transitions follow between various vibrational levels of the lower electronic state, with thermal energy release:

$$\mathrm{HCHO^*} \xrightarrow{q} \mathrm{HCHO}$$

In consequence, light emission should appear first in the form of a bluish flame, and it should be followed by thermal emission; this picture agrees with the experimental facts.

The intensity of the thermal emission increases towards the front of the flame since:

— the vibrational deactivation is unlikely and takes place at low rate as compared to the electronic deactivation,

— the vibrational deactivation appears after the electronic deactivation.

This effect was confirmed experimentally and is illustrated in Fig. 3, where the temperature distribution in the flame is shown for three different flow rates.[14]

The figure shows that the flame length is between 1 and 1.5 cm, while the temperature difference between the top and the base of the flame is of about 200—250°.

It was shown experimentally [15] that in the range of low temperatures, after the preliminary formation of the cool flame, the self-ignition appears, which is a characteristic of all branching-chain reactions.

In the case of the initiated oxidation reaction of methane, the ignition phenomenon was observed to appear when the methane amount was reduced in the mixture.

This fact is shown in Fig. 4, which gives the variation of ΔT versus initiator concentration (HNO_3) for various compositions of the air-methane gaseous mixture.

One can see that the ignition phenomenon appears in the case of low methane content mixtures, in which the flame turns from bluish to yellow and the temperature raises above 1200°.

For the 1000 cm^3/min air + 200 cm^3/min CH_4 and 1200 cm^3/min air + 200 cm^3/min CH_4 mixtures, the self-ignition would be possible for higher initial temperatures of the reactor or by a preheating of the gaseous mixture.

After an interval of temperature increase, an interval in which the temperature remains constant follows, independent of the initiator concentration in the mixture or the composition of the air—CH_4mixture.

We should also note the existence of the two ignition limits as a function of the concentration of nitric acid.

From Fig. 4 a continuity may be seen to exist between the cool flame effect and the ignition effect; the cool flame represents a large part of the reaction.

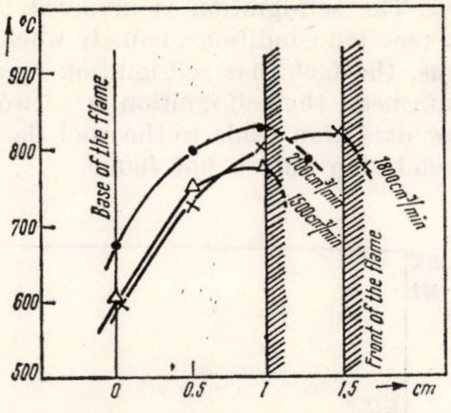

Fig. 3. – Temperature distribution in the flame.

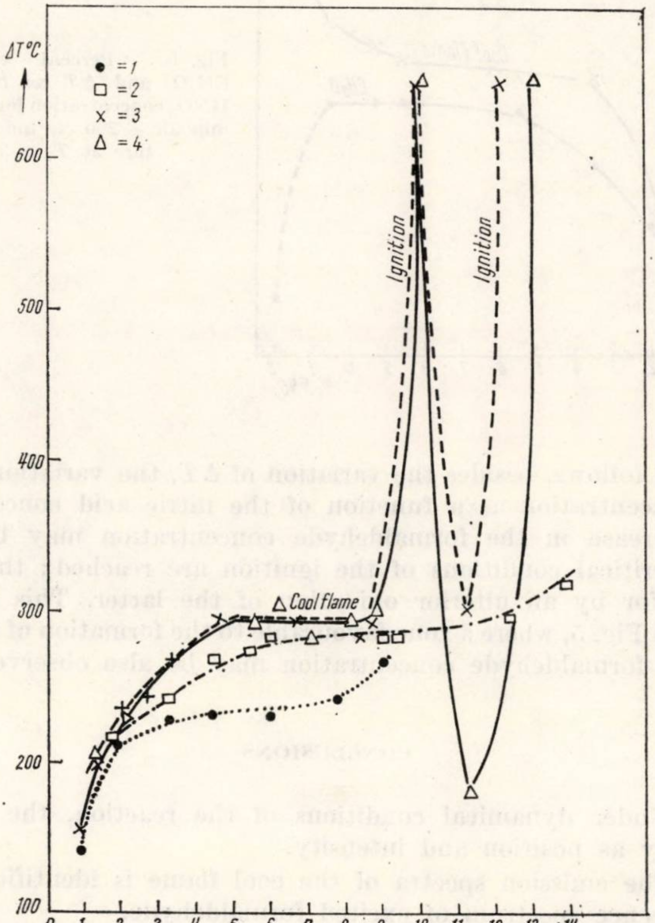
Fig. 4. – The limits of the self-ignition as a function of HNO_3 concentration, for various compositions of the air-methane mixture and $T_i = 557°$.

1, 1000 cm^3/min air + 200 cm^3/min CH_4; *2*, 1200 cm^3/min air + 200 cm^3/min CH_4; *3*, 1400 cm^3/min air + 200 cm^3/min CH_4; *4*, 1600 cm^3/min air + 200 cm^3/min CH_4.



The self-ignition is involved here as a result of modifications in the reaction conditions, namely when some critical conditions are reached. Thus, the fact that self-ignition appears after cool flame formation [15] is confirmed; the self-ignition is a two-step process: in the first step, the slow oxidation leads to the cool flame formation, which becomes in the second step only a hot flame.

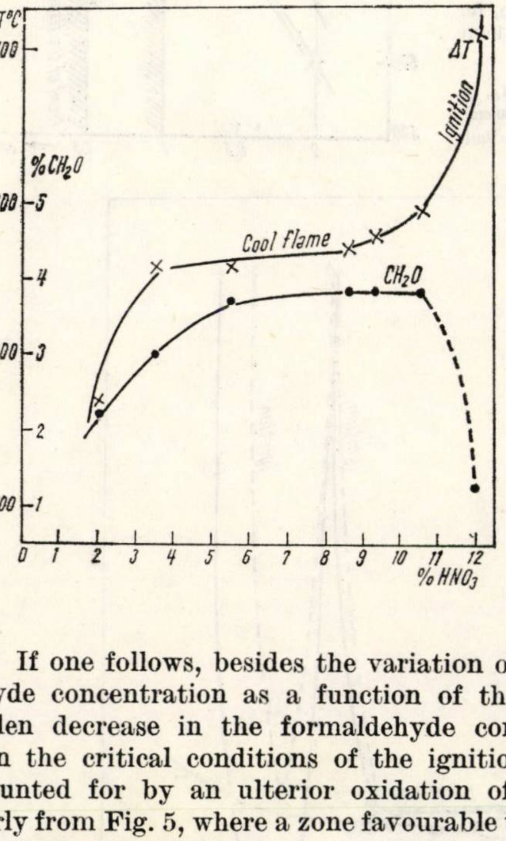


Fig. 5. — Percent variation of CH_2O and ΔT as functions of HNO_3 concentration for a 1400 cm³/min air + 200 cm³/min CH_4 mixture at $T_i = 557°$.

If one follows, besides the variation of ΔT, the variation of formaldehyde concentration as a function of the nitric acid concentration, a sudden decrease in the formaldehyde concentration may be observed when the critical conditions of the ignition are reached; this could be accounted for by an ulterior oxidation of the latter. This fact results clearly from Fig. 5, where a zone favourable to the formation of a maximum and steady formaldehyde concentration may be also observed.

CONCLUSIONS

1 — Under dynamical conditions of the reaction, the cool flame is stationary as position and intensity.

2 — The emission spectra of the cool flame is identified as being the fluorescence spectrum of excited formaldehyde.

3 — Both the cool flame and the ignition are favoured in low methane content mixtures.

4 — There is a continuity between the cool flame phenomenon and the ignition phenomenon; the cool flame constitutes an important part of the reaction.

5 — It is confirmed that the hydrocarbon self-ignition at low temperatures is a two-stage process; in the first stage, the slow oxidation leads to the cool flame formation and the reaction development in the second stage leads to the hot flame formation.

KINETICS OF THE FORMATION REACTIONS OF OXYDIC COMPOUNDS IN SOLID PHASE THROUGH DIFFERENTIAL THERMAL ANALYSIS *)

S. SOLACOLU, M. CERCHEZ and E. SEGAL

Institute of Physical Chemistry, Str. Galați 31,
Bucharest-9, Romania

Received July 10, 1972

For reactions which take place without variation of weight

$$nA\,(s) + mB\,(s) \rightarrow A_nB_m(s) - \Delta H\;^{**)}$$

a kinetic study is undertaken making use of the data given by the differential thermal analysis. An original method, based on the use of kinetic equations established in the hypothesis that the analysed processes are controlled by diffusion, was devised.

1. INTRODUCTION

The use of differential thermal analysis to the study of the kinetics of chemical reactions is recommended by different authors. [1–3] The method is based on the direct proportionality existing between the reaction enthalpy, that can be measured, and the quantity of reacted substance. [3] The thermogravimetric methods and the methods using differential thermal analysis, were especially applied to investigate the kinetics of heterogeneous decomposition reaction taking place with gas release. [1,2,4–8] The methods of determining the reaction kinetics, from DTA data, for the formation reactions of oxydic compounds, of the following form:

$$nA(s) + mB(s) \rightarrow A_nB_m(s) - \Delta H \qquad \text{(I)}$$

are unknown. The kinetics of these reactions, which take place without a weight variation in the system, can not be determined by thermogravimetry.

We present below a kinetic study of a type (I) chemical process using the data of differential thermal analysis.

An original method was therefore worked out, based on the use of some kinetic equations established in the hypothesis that the processes submitted to analysis are controlled by diffusion.

To illustrate the proposed method, we present below the determination of the kinetic formation parameters of bismuth titanate $4Bi_2O_3 \cdot TiO_2$ which is a member of the bismuth titanate class with important uses in the field of dielectric ceramics and especially for masses having ferroelectrical properties.[9,10] For this compound the reaction kinetics is unknown.[11]

2. CALCULATION TECHNIQUE

2.1. DEDUCTION OF RELATIONSHIPS USED TO CALCULATE THE KINETIC PARAMETERS. CALCULATION PROCEDURE BY PROCESSING THE KINETIC EQUATION IN INTEGRAL FORM IN NON-ISOTHERMAL WORKING CONDITIONS

We shall consider as an example the kinetic equation suggested by Jander for the chemical processes, with a reaction rate controlled by tridimensional diffusion.[7,12]

Jander's equation may be written in the following form

$$1 - 2(1-\alpha)^{1/3} + (1-\alpha)^{2/3} = kt^{*)} \qquad (1)$$

After differentiation and rearrangement one obtains

$$[(1-\alpha)^{-2/3} - (1-\alpha)^{-1/3}]\,\mathrm{d}\alpha = \frac{3}{2}k\,\mathrm{d}t \qquad (2)$$

But

$$\frac{\mathrm{d}T}{\mathrm{d}t} = a \qquad (3)$$

where a – is the heating rate and

$$k = Z\exp(-E/RT) \qquad (4)$$

where

Z – is the pre-exponential factor
E – the activation energy (cal/mol)
R – the gas constant (cal/mol^{-1} K^{-1})
T – the absolute temperature (K).

---

*) It was noted : α – the transformation degree, t – the time, k – the kinetic constant.

[9] L. E. Cross and R. C. Pohanka, *Mater. Res. Bull.*, **6**, 939 (1971).

[10] R. E. Newnham, R. W. Wolfe and J. F. Dorian, *Mater. Res. Bull.*, **6**, 1029 (1971).

[11] Gh. Morar, *Rev. Roumaine Chim.*, (in printing).

[12] C. Kröger and J. Blömer, *Z. anorg. Chem.*, **280**, 51 (1955).

After replacing relations (3) and (4) in equation (2), inclusion of the numeric fraction in the constant $\left(\frac{3k}{2} = k_0\right)$ and integration, there results the following equation for the entire display field of the reaction

$$\int_0^{\alpha} [(1-\alpha)^{-2/3} - (1-\alpha)^{-1/3}]\, d\alpha = \frac{k_0}{a} \int_{T_0}^{T_\alpha} \exp\left(-\frac{E}{RT}\right) \tag{5}$$

To solve the integral in the right member of the equation (5) (temperature), we have used an approximate method, generally employed.[8] We thus obtained

$$\frac{1}{2}[1 + (1-\alpha)^{2/3}] - (1-\alpha)^{1/3} = \frac{k_0\, RT^2}{3aE}\left(1 - \frac{2RT}{E}\right) \exp\left(-\frac{E}{RT}\right) \tag{6}$$

which after logarithmation becomes

$$\log \frac{1}{T^2}\left\{\frac{1}{2}[1 + (1-\alpha)^{2/3}] - (1-\alpha)^{1/3}\right\} = \log \frac{k_0 R}{3aE}\left(1 - \frac{2RT}{E}\right) - \frac{E}{4.575\ T} \tag{7}$$

If one admits that the total area A between the DTA curve (fig. 1) and the base line is proportional to the entire quantity of transformed substance, and the area a, limited by the DTA curve, the base line and the ordinate corresponding to moment t_i, is proportional to the quantity of substance transformed till that moment, the transformation degree of equation (7) may be expressed by

$$\alpha = \frac{a}{A} \tag{8}$$

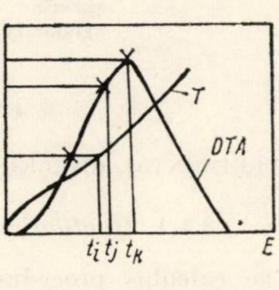

Fig. 1. — Diagram of the variation of the sample temperature and of the temperature difference between the sample and the actionless substance versus time.

By introducing it into equation (7), there results

$$\log \frac{1}{T^2}\left\{\frac{1}{2}\left[1 + \left(1 - \frac{a}{A}\right)^{2/3}\right] - \left(1 - \frac{a}{A}\right)^{1/3}\right\} = \log \frac{k_0 R}{3aE}\left(1 - \frac{2RT}{E}\right) - \frac{E}{4.575\ T} \tag{9}$$

To determine the activation energy we notice that the plotting of values

$$\log \frac{1}{T^2} \left\{ \frac{1}{2} \left[1 + \left(1 - \frac{a}{A} \right)^{2/3} \right] - \left(1 - \frac{a}{A} \right)^{1/3} \right\} \quad \text{versus} \quad \frac{1}{T}$$

leads to a line with a slope bound to the activation energy by the relation

$$E \text{ (cal/mol)} = 4.575 \ \mathrm{tg}\, \beta. \tag{10}$$

Table 1 gives the analogous calculation formulae for other known kinetic equations, usually applied to reactions with a rate controlled by diffusion phenomena.

Table 1

Calculus relations of reaction kinetics for formation mechanisms of solid phase compounds with the reaction rate controlled by diffusion

N⁰	Equation	Diffusion type	Name of equation	Calculation formula of activation energy. Procedure of processing the integral equation
1.	$\alpha^2 = 2kt$	Unidimensional diffusion	Jander [13]	$\log \frac{1}{T^2} \frac{\left(\frac{a}{A}\right)^2}{2} = \log \frac{kAR}{aE} \left(1 - \frac{2RT}{E}\right) - \frac{E}{4.575\ T}$
2.	$[1-(1-\alpha)^{1/3}]^2 = kt$	Tridimensional diffusion spheric symmetry	Jander [13]	$\log \frac{1}{T^2} \left\{ \frac{1}{2} \left[1 + \left(1 - \frac{a}{A}\right)^{2/3} \right] - \left(1 - \frac{a}{A}\right)^{1/3} \right\} = \log \frac{k_0}{3a} \frac{R}{E} \left(1 - \frac{2RT}{E}\right) - \frac{E}{4.575\ T}$
3.	$1 - \frac{2}{3}\alpha - (1-\alpha)^{2/3} = kt$	Tridimensional diffusion spheric symmetry	Ginstling-Brounshtein [14]	$\log \frac{1}{T^2} \left\{ \frac{3}{2} \left[1 - \left(1 - \frac{a}{A}\right)^{2/3} - \alpha \right] - \frac{a}{A} \right\} = \log \frac{k_0}{a} \frac{RT^2}{E} \left(1 - \frac{2RT}{E}\right) - \frac{E}{4.575\ T}$

3. EXPERIMENTAL RESULTS

3.1. EXPERIMENTAL CHECKING OF THE PROPOSED CALCULUS RELATIONS

3.1.1. *Qualitative study of $4Bi_2O_3 \cdot TiO_2$ formation*

The calculus procedure was applied for checking the formation reaction of compound $4Bi_2O_3 \cdot TiO_2$, recently identified as such, and not as a term in a solid solution.[15]

---

[15] E. I. Speranskaia, I. S. Rez, L. V. Kozlova, V. M. Skorikov and V. I. Slavov, *Izvest. Akad. Nauk S.S.S.R., Neorg. Mater.*, **1**, 232 (1965).

Figure 2 gives the DTA curve of the stoichiometric mixture of Bi_2O_3 and TiO_2. Three thermal effects are pointed out on the curve: an exothermal one between 610 and 700° having a maximum at 670°, and two endothermal ones with the maxima at 730° and respectively at 865°.

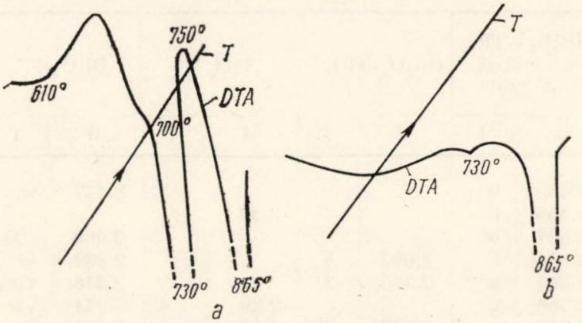

Fig. 2. — Differential thermal analysis of the stoichiometric mixture $4Bi_2O_3 + TiO_2$.
a) initial oxydic mixture; b) mixture calcinated at 725°.

In agreement with Speranskaia *et al.*,[15] the endothermal effects are ascribed to the polymorphous transformation $\beta Bi_2O_3 \rightarrow \alpha Bi_2O_3$ and, respectively, to the fusion $4Bi_2O_3 \cdot TiO_2 (s) \rightarrow 4Bi_2O_3 \cdot TiO_2 (l)$. The exothermal effect with a maximum at 670° was ascribed by us to the formation, in solid phase, of the compound $4Bi_2O_3 \cdot TiO_2$. The checking of this hypothesis was confirmed by thermal analysis of the sample calcinated at 725° (figure 2b). We notice that only the melting effect of the formed compound appears markedly on the curve, fact showing the actual formation of $4Bi_2O_3 \cdot TiO_2$; the attenuation up to nearly the base line of the polymorphous transformation effect of Bi_2O_3 shows that the largest part of the Bi_2O_3 quantity has reacted.

The checking of the compound formation was also carried out by roentgenography through analysis of the mixture calcinated at 725° and 575°. At 725° the characteristic lines $4Bi_2O_3 \cdot TiO_2$ were identified besides the TiO_2 and BiO_3 lines (table 2). We mention the fact that owing to the numerous coincidences between $4Bi_2O_3 \cdot TiO_2$ and Bi_2O_3, and to the fact that the solid phase reaction is in an incipient phase, only the intensive individual lines, characteristic for the initial oxides and for titanate, were considered decisive for identification.

The fact that among the Bi_2O_3 lines, the intense lines with $d = 1.63 - 1.65$ Å (20–100) and $d = 1.65 - 1.75$ Å (70–100) are missing, also proves the important desintegration of the initial oxide network at the reaction with TiO_2.

3.1.2. *Kinetic study of $4Bi_2O_3 \cdot TiO_2$ formation. Discussion of results*

For quantitative measurements in reaction kinetics the recording of DTA curves was carried out with the thermoderivatograph M.O.M.-Budapest, in air, with the sensitivity of the DTA galvanometer at 1/2.

Heating rate : 10°/minute. The fineness of the oxides used corresponds to a granulation < 60 μm.

The values of the surfaces of the exotherm effect on the DTA curve corresponding to the different moments of the reaction were initially determined, both by planimetric calculation and by weighing the copying paper cut to correspond to the surface after plotting the effect.

As the gravimetric methods give marked nonconformities for very small values of the transformation gradient (table 3), owing to the variation of the paper density and to the weighing errors, only the data obtained by planimetric calculus were capitalized for kinetic calculations.

Figure 3 gives graphically the reaction kinetics calculated according to Jander's equation (9).

As it results from relation (10), the value of the activation energy is of 229 kcal/mol (fig. 3).

---

[17] A.S.T.M. 2–0547.

To check the order of magnitude of the activation energy of the reaction, we have used the approximate calculation method of considering the dynamic process as an infinity of isothermal processes. [7,18] The logarithm of the rate constant for different time periods was thus calculated, and plotted versus $\frac{1}{T}$ (fig. 4).

[18] D. Cismaru, *St. cerc. fiz.*, **6**, 435 (1955); *St. cerc. chim.*, **5**, 119 (1957); **5**, 673 (1957); **6**, 539 (1958).

This method gives the value of the activation energy at 200 kcal/mol showing a satisfactory agreement with the order of magnitude of the value determined by the preceeding method.

The initially obtained value of 229 kcal/mol is considered as a significant value, as this method, generally used to determine the reaction kinetics, is recommended as more precise.[8,19]

The high value of the activation energy shows a maximum energetic contribution to the formation of this titanate of the same order of magnitude as, for instance, in the case of Pb_2SiO_6 formation.[20]

4. CONCLUSIONS

1. — Calculus expressions of the activation energy were established for chemical reactions of the type

$$nA\,(s) + mB\,(s) \rightarrow A_nB_m(s) - \Delta H$$

based on the data obtained from the DTA curve, in the hypothesis that the reaction rate is controlled by diffusion phenomena.

2. — For exemplification, the kinetics of the formation reaction of $4Bi_2O_3 \cdot TiO_2$ between 610 and 700°, of the initial stoichiometric mixture of Bi_2O_3 and TiO_2 oxides, according to Jander equation, was presented.

TEMPERATURE AND CONCENTRATION DEPENDENCE OF MOLAR POLARIZATION IN BINARY MIXTURES OF POLAR LIQUIDS WITH NONPOLAR SOLVENT

IUDITA ADORIAN

Department of Physical Chemistry, Polytechnical Institute
Str. Polizu 1, Bucureşti, Romania

Received July 27, 1972

Dielectric constants, refractive indices and densities of cyclohexane-nitrobenzene, cyclohexane-chlorobenzene and cyclohexane-ethyl benzoate mixtures have been measured at various concentrations and temperatures. Positive deviations from additivity of the molar polarization and the molar volumes are reported. The temperature dependence on the orientation polarization of the polar components, at various concentrations is discussed.

The study of molar polarization of polar liquids in nonpolar solvents was the object of various papers in the period 1920–1940, especially in view of the determination of permanent electric moments at law concentration. Subsequently, the area of these studies extended to include the investigation of the dielectric behaviour of liquid mixtures in the full range of concentrations, with the purpose of obtaining some information about the molecular interactions, from the exhibited deviations from additivity.

Along this line of investigation are to be mentioned the experimental works of Williams, [1] Smyth, [2] e.a., as well as those of Wolfke, [3] Malsch, [4] van Arkel and Snoek [5] that attempted to account for dipolar interactions by introducing some formal corrections in the expression of the polarization. The theoretical treatment of the mutual influence of the permanent dipoles in liquid state was first made by Debye, [6] Onsager, [7] Kirkwood [8] and developed subsequently by others. [9-11] In recent years the dielectric behaviour of liquid mixtures became a subject of interest for many investigators. [12-21] This regain of interest can be explained both by the fact that the theoretical progress makes possible a better interpretation of the results and by the development of new experimental techniques (study of dielectric relaxation, i.r. spectrography, NMR), which yield informations mutually complementary to the study of electrostatic polarization.

In the present paper, results concerning concentration and temperature dependence or orientation polarization in low frequency field, of polar liquids dissolved in nonpolar solvent, are presented. The behaviour of some benzene derivatives: nitrobenzene, chlorobenzene and ethyl benzoate in mixture with cyclohexane has been studied. The investigated concentration range was $x_2 = 0.1-0.9$ (x_2 — mole fraction of the polar component). The temperature range investigated (15°—70°) covers the greatest part of the temperature range in which the above mentioned systems are in the liquid state.

EXPERIMENTAL PART

Substances used: nitrobenzene p.a. dried on P_2O_5 and distilled $n_D^{20} = 1.5525$; chlorobenzene p.a. distilled $n_D^{20} = 1.5244$; ethyl benzoate p.a. distilled $n_D^{20} = 1.5048$ and cyclohexane dried on P_2O_5 and distilled $n_D^{20} = 1.4260$.

Measurements of dielectric constants were carried out with a heterodyne beat apparatus at a frequency of 0.5 MHz (stabilized with a piesoelectric quartz crystal). There is a linear relationship between the value read on the scale of the apparatus and the measured capacity. The cells used consisted of two concentric cylinders with 9.37 pF and 12.8 pF effective capacity, respectively.

Density measurements have been carried out with a pycnometer with a volume of $14.5181 + 0.0003\ (t - 20°)$ cm^3.

Measurements of the refractive index were performed by means of a Pulfrich refractometer. As monochromatic light source a sodium vapour lamp was used.

The temperature of the pycnometer, dielectric-cell and refractometer was kept constant within ±0.1° using a Höppler ultrathermostate with external circulation. The temperature was measured in three points of the circuit.

The solutions used were prepared freshly in glass flasks with ground cap and the concentrations were established by weighing on an analytical balance.

RESULTS

The dielectric constants of the cyclohexane-nitrobenzene, cyclohexane-chlorobenzene and cyclohexane-ethyl benzoate mixtures at various values of the mole fraction x_2, of the polar component and at various temperatures are presented in table 1.

Table 1

In table 2 the refractive indices and in table 3 the densities of the above mentioned mixtures are reported.

The dielectric constants exhibit negative deviations from the additivity in the cyclohexane-nitrobenzene and cyclohexane-chlorobenzene system and positive ones in the cyclohexane-ethyl benzoate system. By increasing the temperature the dielectric constants decrease and the departures from additivity too. The densities of the mixtures decrease linearly with the temperature and present small negative deviations from additivity. The refractive indices are quasi-additive.

The molar polarizations $P_{1,2}$ of the mixtures have been calculated by Debye's equation

$$P_{1,2} = \frac{\varepsilon_{1,2} - 1}{\varepsilon_{1,2} + 2} \cdot \frac{M_{1,2}}{d_{1,2}} = P_1x_1 + P_2x_2 \tag{1}$$

where $\varepsilon_{1,2}$ and $d_{1,2}$ are the dielectric constants and the density of the mixtures respectively, and $M_{1,2} = x_1M_1 + x_2M_2$ (x_1 and x_2 being the mole fractions of the nonpolar and the polar component respectively).

In fig. 1 the 20° isotherms of the molar polarization of the three mixtures are presented, as calculated by equation (1). Positive deviations from additivity are observed in all cases, the largest one in the case of the cyclohexane-nitrobenzene system. Large positive molar polarization deviations are usually observed simultaneously with large negative deviations of the dielectric constant. [18] The deviations from ideal behaviour decrease with increasing temperature.

Molar polarizations of the mixtures calculated by the Kirkwood-Onsager equation

$$P = \frac{(\varepsilon - 1)(2\varepsilon + 1)}{9\varepsilon} \cdot \frac{M_{1,2}}{d_{1,2}} \tag{2}$$

vary linearly with the concentration in the cyclohexane-chlorobenzene and cyclohexane-ethyl benzoate systems and present a small deviation from additivity in the cyclohexane-nitrobenzene system.

The molar refraction calculated by the Lorenz equation

$$R_{1,2} = \frac{n_{1,2}^2 - 1}{n_{1,2}^2 + 2} \cdot \frac{M_{1,2}}{d_{1,2}} \tag{3}$$

varies linearly with the concentration in each case.

In fig. 3 the $R_{1,2} = f(x_2)$ isothermes at 20° are presented.

In fig. 4 the molar volumes at 20° of the three mixtures are presented. Small positive deviations from the ideal state are observed, which decrease with increasing temperature. The excess volumes at two temperatures for the cyclohexane-chlorobenzene and cyclohexane-nitrobenzene mixtures are presented in figures 5 and 6.

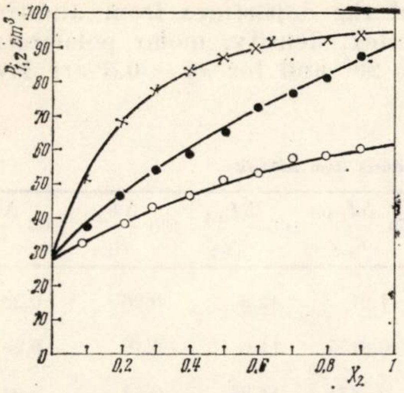

Fig. 1. — Molar polarization calculated with equation (1) of the cyclohexane-nitrobenzene x, cyclohexane-chlorobenzene o and cyclohexane-ethyl benzoate• mixtures.

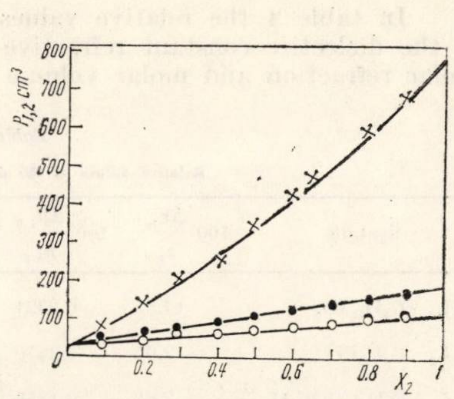

Fig. 2. — Molar polarization calculated with equation (2) of the cyclohexane-nitrobenzene x, cyclohexane-chlorobenzene o and cyclohexane-ethyl benzoate• mixtures.

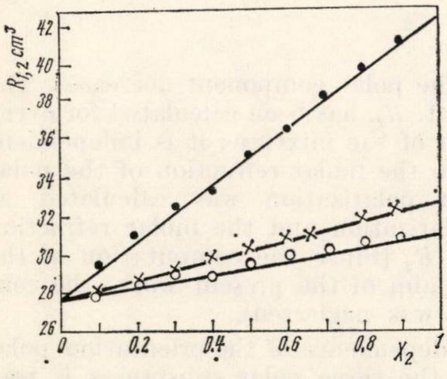

Fig. 3. — Molar refraction of the cyclohexane-nitrobenzene x, cyclohexane-chlorobenzene o and cyclohexane-ethyl benzoate• mixtures.

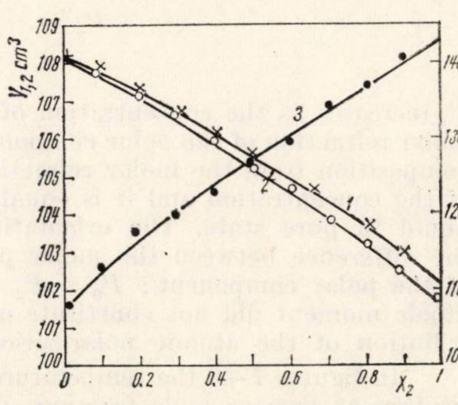

Fig. 4. — Molar volume of the cyclohexane-nitrobenzene. 1, x, cyclohexane-chlorobenzene 2, and cyclohexane-ethyl benzoate 3, mixtures. (the right-hand scale concerns the cyclohexane-ethyl benzoate mixture).

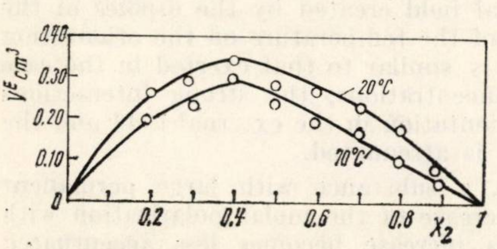

Fig. 5. — Integral excess molar volume of the cyclohexane-chlorobenzene mixture.

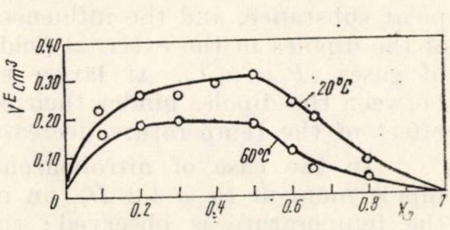

Fig. 6. — Integral excess molar volume of the cyclohexane-nitrobenzene mixture.

In table 4 the relative values of the departures from additivity of the dielectric constant refractive index, density, molar polarization, molar refraction and molar volume at 20° and for $x_2 = 0.5$ are given.

Table 4

Relative values of the departures from additivity

System	$100\,\frac{\Delta\varepsilon_{1,2}}{\varepsilon_{1,2}}$	$100\,\frac{\Delta n_{1,2}}{n_{1,2}}$	$100\,\frac{\Delta d_{1,2}}{d_{1,2}}$	$100\,\frac{\Delta P_{1,2}}{P_{1,2}}$	$100\,\frac{\Delta R_{1,2}}{R_{1,2}}$	$100\,\frac{\Delta V_{1,2}}{V_{1,2}}$
$C_6H_{12}-C_6H_5NO_2$	−17.55	−0.2221	−1.01	42.8	0.26	0.29
$C_6H_{12}-C_6H_5Cl$	− 2.65	−0.2270	−0.8175	11.6	0.10	0.28
$C_6H_{12}-C_6H_5COOC_2H_5$	2.68	0.1855	0.7875	11.25	0.54	0.94

Based on equation (1) the molar polarization of the polar component can be calculated

$$P_2 = \frac{P_{1,2} - P_1 x_1}{x_2} \tag{4}$$

P_2 increases as the concentration of the polar component decreases. The molar refraction of the polar component, R_2, has been calculated for every composition from the molar refraction of the mixture; it is independent of the concentration and it is equal to the molar refraction of the polar liquid in pure state. The orientation polarization was calculated as the difference between the molar polarization and the molar refraction of the polar component: $P_0 = P_2 - R_2$ (Since the computation of the dipole moment did not constitute an aim of the present work, the contribution of the atomic polarization was neglected).

In figures 7—9 the temperature dependence of the orientation polarization at various mole fractions of the three polar substances is presented. It is to be noted that the orientation polarization decreases with increasing temperature for chlorobenzene and ethyl benzoate, the increase being more marked as the concentration of the polar component gets smaller. The dispersion of the polar molecules in the nonpolar liquid diminishes the effect of the internal field created by the dipoles of the polar substance, and the influence of the temperature on the orientation of the dipoles in the external field is similar to that exerted in the case of gases ($P = a/T$). At larger concentrations, the strong interactions between the dipoles hinder their orientation in the external field and the effect of the temperature decrease is attenuated.

In the case of nitrobenzene, a substance with large permanent dipole moment ($\mu = 4.2\ D$), an increase of the molar polarization with the temperature is observed; this increase becomes less accentuated as the concentration decreases, and at small concentrations a decrease of the molar polarization can be observed as in the previous two cases. This reversal of the slope was observed also at other strongly polar substances. [2] The behaviour of the nitrobenzene in pure state and at high concentration can be explained by the existence of associations of the dipoles, that dissimulate to some extent the dipole moment. With increasing temperature dissociation takes place and the molar polarization increases. With small concentrations there is no association and the effect of the temperature consists in a randomization of the orientation of the free dipoles relative to the external field.

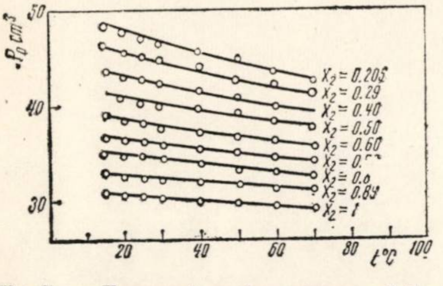

Fig. 7. — Temperature dependence of the orientation polarization of chlorobenzene.

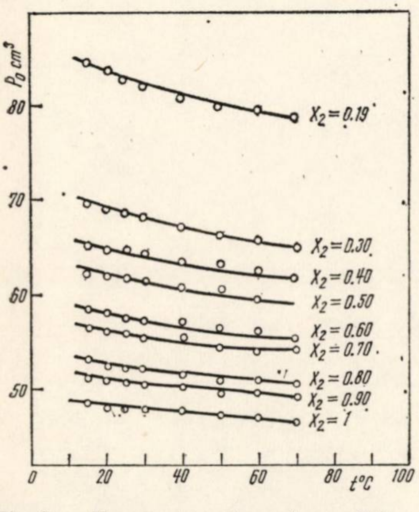

Fig. 8. — Temperature dependence of the orientation polarization of ethyl benzoate.

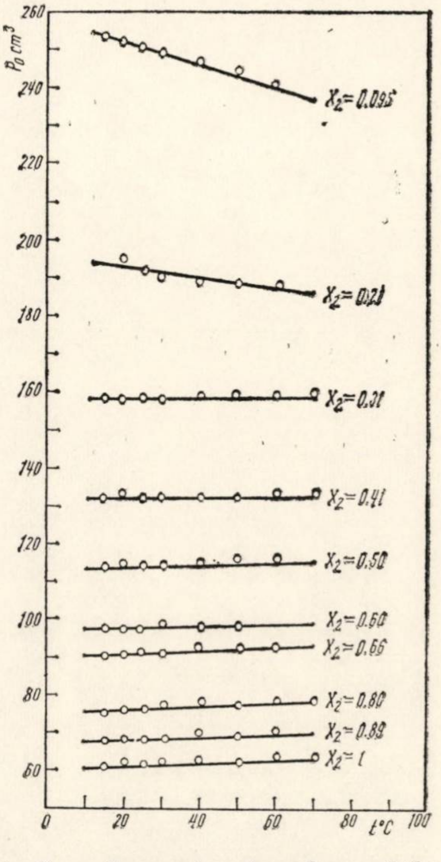

Fig. 9. — Temperature dependence of the orientation polarization of nitrobenzene.

The chronopotentiometric method has been applied in the molten alkali nitrates systems, $NaNO_3-AgNO_3$ and KNO_3-AgNO_3, for $AgNO_3$ concentrations of $0.5 - 2 \times 10^{-2}$ mole $\cdot l^{-1}$ and current densities of $5 - 30 \times 10^{-3}$ A $\cdot$ cm^{-2}. It was shown that the capacitive current may be neglected in optimal conditions. At low concentrations and high current densities the chronopotentiograms are strongly distorted by the electric double layer charging. A method to correct the transient of the distorted chronopotentiogram and to estimate the capacitive current is proposed.

In recent years, the chronopotentiometric method has been applied to many binary systems of molten salts, by recording the potential-time curves through galvanostatic polarization.

Assuming that the transport of the ion to the electrode is effected exclusively by the semi-infinite linear diffusion process, the interdiffusion coefficient (D) can be calculated using Sand's equation

$$\tau^{1/2} = \frac{\pi^{1/2} nFD^{1/2} c}{2i} \qquad (1)$$

where

τ — chronopotentiometric transient

i — current density

c — ion concentration

n — number of electrons which participate at the electrode reaction

F — Faraday's constant.

The transient is measured on the chronopotentiogram by one of the graphical methods proposed.[1-4]

Fig. 1 represents a typical chronopotentiogram which illustrates the procedure for the determination of the transient. This procedure will be referred to as "the graphical method of Reinmuth".[3] It should be mentioned that in this method, the precise measurement of the potential variation is not necessary; only the exact evaluation of the transient τ is required.

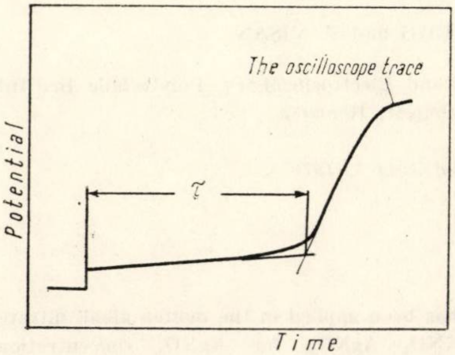

Fig. 1. — A typical chronopotentiogram. τ — the transient.

In deducing equation (1) it has been assumed that the electrical current was entirely used in the faradic process. In reality, because the potential varies continuously in time, a fraction of the total current is used for charging the electrical double layer, i.e. there exists a diffusive (faradic) and a capacitive current, i_F and i_c, which satisfy the relation

$$i = i_F + i_c \tag{2}$$

In the following, an analysis of the role of the capacitive current during the cathodic chronopotentiometric polarization in fused salt solutions is presented. At the same time, it is interesting to note that the problem is of practical importance. Thus, in very diluted solutions, or for high current densities, the capacitive current becomes sufficiently great and, consequently, for a correct interpretation of the experimental chronopotentiograms, it is necessary to estimate it.

Under these conditions, the chronopotentiograms are strongly distorted, so that the direct measurement of the transient by drawing tangents at the potential-time curve, becomes inapplicable.

The present paper suggested, in a first approximation, a method for determining the transient, starting from Nernst's relation, which for

[2] P. Delahay and T. Berzins, *J. Amer. Chem. Soc.*, **75**, 2486 (1953).

[3] W. H. Reinmuth, *Analyt. Chem.*, **33**, 485 (1961).

[4] C. D. Russell and J. M. Peterson, *J. Electroanalyt. Chem.*, **5**, 467 (1963).

the linear semi-infinite diffusion takes the following form

$$E = E^{\circ} + \frac{RT}{nF} \ln\left(c - \frac{2it^{1/2}}{\pi^{1/2} nFD^{1/2}}\right) \tag{3}$$

If E and E_1 represent the cathodic potentials corresponding to the variable time t and to the fixed time t_1 (t_1 may be also zero), then we find the equation

$$\Delta E = E - E_1 = \frac{RT}{nF} \ln \frac{\pi^{1/2}\, nFD^{1/2}c - 2it^{1/2}}{\pi^{1/2}\, nFD^{1/2}c - 2it_1^{1/2}} \tag{4}$$

We could write the equation (4) in the following form

$$1 - \exp\left(\frac{nF\Delta E}{RT}\right) = \frac{2i}{\pi^{1/2}\, nFD^{1/2}\, c}\left[t^{1/2} - t_1^{1/2} \exp\left(\frac{nF\Delta E}{RT}\right)\right] \tag{5}$$

The quantity ΔE is measured at different times t (maintaining t_1 at a fixed value). In a system having the co-ordinates : $1 - \exp\left(\frac{nF\Delta E}{RT}\right)$ and $t^{1/2} - t_1^{1/2} \exp\left(\frac{nF\Delta E}{RT}\right)$ a curve is obtained, the initial linear portion of which, extrapolated for the ordinate equal to 1 ($\Delta E \to -\infty$), gives the measured transient $\tau_m^{1/2}$.

We shall call this procedure of transient evaluation "the $E - t$ linear equation method" or shortly "the $E - t$ method".

By this method we obtain a first correction of the chronopotentiograms, through an improved determination of the transient. The transient obtained by the $E - t$ method is corrected, by introducing in the Sand's equation a faradic current $i_F = i - i_c$.

The capacitive current is computed from the relation

$$i_c = -C_{dl}\frac{\mathrm{d}E}{\mathrm{d}t} = C_{dl}\frac{RT}{nF}\frac{1}{2\,t^{1/2}\,(\tau^{1/2} - t^{1/2})} \tag{6}$$

In relation (6), C_{dl} represents the differential capacity of the double layer per surface unit, the capacity being considered constant for a certain potential range.

The second factor of the same relation results from the differentiation of the relation (3), at the same time, taking into account Sand's equation. [5]

It is clear that equation (6) has an approximate character because the current density i of equation (3) has been considered constant.

---

[5] Iu. K. Delimarskii, A. V. Gorodyskii and V. V. Kuzmovich, *Coll. Czech. Chem. Comm.*, **25**, 3056 (1960).

In reality, one must consider the faradic current i_F, which varies in time.

Such a treatment was applied by De Vries on the basis of a programme, using a computer. [6]

We shall further use equation (6) for an approximate computation of the capacitive current.

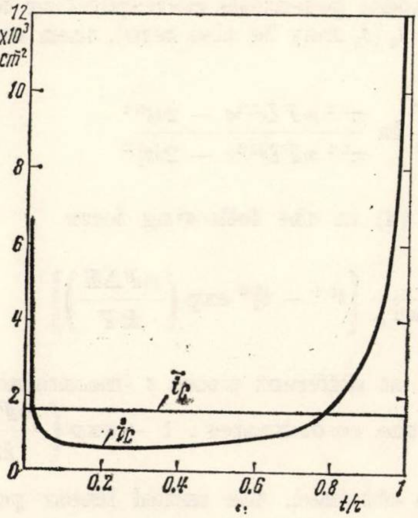

Fig. 2. — The capacitive current in $NaNO_3-AgNO_3$ system. $c_{AgNO_3} = 0.5 \times 10^{-2}$ mole$\cdot l^{-1}$, $i = 15 \times 10^{-3}$ A$\cdot$cm^{-2}, $t = 350°$.

Fig. 2 represents the capacitive current i_c computed by relation (6) for a distorted chronopotentiogram. It may be seen that for a sufficiently great time interval (*ca* 0.8 τ), i_c does not vary too much; thus one can take an average capacitive current with the aid of which one may proceed to a second correction of the chronopotentiograms.

EXPERIMENTAL

The determinations were performed in the molten alkali nitrates systems $NaNO_3-AgNO_3$ and KNO_3-AgNO_3, with $AgNO_3$ concentrations of $0.5-2.0 \times 10^{-2}$ mole$\cdot$l^{-1} and current densities of $5-30 \times 10^{-3}$ A$\cdot$cm^{-2}, on a cathode platinum plate. The temperature was maintained constant at 350 ± 0.5°, and the recording of the potential-time curves was effected directly on the photographic paper from cathode-ray oscillograph.

The electrical assembling, the cell, the electrodes and the working procedure are described elsewhere. [7]

RESULTS AND DISCUSSION

Fig. 3 shows a distorted chronopotentiogram, for which the drawing of the tangents for the measurement of the transient becomes very difficult. Fig. 4 shows the $E - t$ method proposed by us for the determination of the transient, through extrapolation of the linear portion of the curve plotted in the coordinates expressed in (5). In this last figure, the chronopotentiogram is a little distorted owing to the low capacitive current, which is practically negligible.

[6] W. T. De Vries, *J. Electroanalyt. Chem.*, **17**, 31 (1968); **18**, 467 (1968).

[7] S. Sternberg and C. Herdlicka, *Rev. Roumaine Chim.*, **14**, 991 (1969); **15**, 343 (1970).

In this situation, the transient obtained by the $E - t$ method is practically equal to that obtained by the Reinmuth's graphical method.

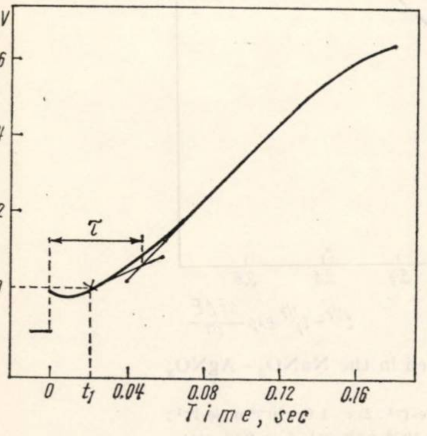

Fig. 3. — A distorted chronopotentiogram in the KNO_3-AgNO_3 system. $c_{AgNO_3} = 0.5 \times 10^{-2}$ mole·l^{-1}, $i = 10 \times 10^{-3}$ A·cm^{-2}, $t = 350°$.

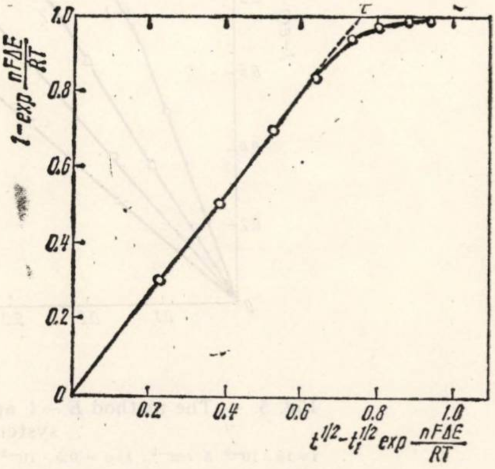

Fig. 4. — The determination of the transient by the method proposed by us (the $E - t$ method). $c_{AgNO_3} = 2.0 \times 10^{-2}$ mole·l^{-1}, in the $NaNO_3 - AgNO_3$ system; $i = 10 \times 10^{-3}$A·cm^{-2}, $t_1 = 0.05$ sec.

In the case of more diluted solutions of Ag^+ ions, the deviation from linearity of the initial portion is more and more pronounced (figs. 5 and 6) and corresponds to a greater distortion of the potential-time curves.

In order to verify the different procedures for the correction of the capacitive current, the interdiffusion coefficient of the Ag^+ ion has been computed from the transients measured by the $E - t$ linear equation method.

In the concentration range used by us, the interdiffusion coefficient D_{Ag^+} is a constant which depends only on the nature of the solvent. Tables 1 and 2 contain the results obtained in this way for D_{Ag^+} in the molten salt systems, $NaNO_3-AgNO_3$ and KNO_3-AgNO_3, at different concentrations and current densities (column 7). Under our working conditions the transients had values ranging between 0.015 and 0.75 seconds.

Tables 1 and 2 contain also the values of the interdiffusion coefficient calculated from direct readings of transients by the Reinmuth's graphical method (column 6). At high concentrations and low current densities the results obtained by the two methods are in very good agreement. In tables 1 and 2 the interdiffusion coefficients obtained from undistorted chronopotentiograms are marked with the sign *.

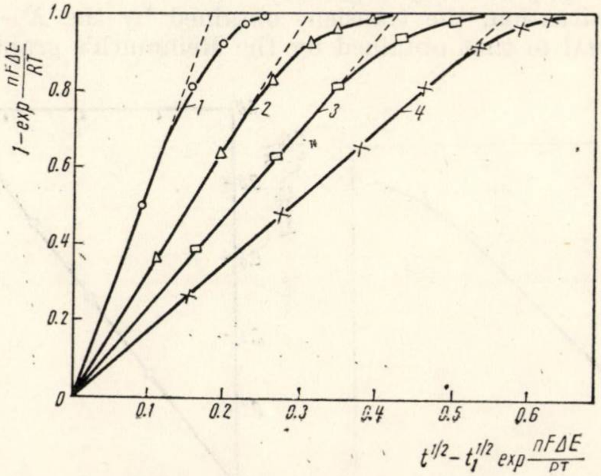

Fig. 5. — The method $E - t$ applied in the $NaNO_3-AgNO_3$ systems.
$i = 15 \times 10^{-3}$ A·cm^{-2}; 1) $c = 0.5 \times 10^{-2}$ mole·l^{-1}; 2) $c = 1.0 \times 10^{-2}$ mole·l^{-1}; 3) $c = 1.5 \times 10^{-2}$ mole·l^{-1}; 4) $c = 2.0 \times 10^{-2}$ mole·l^{-1} $t_1 = 0.01$ sec.

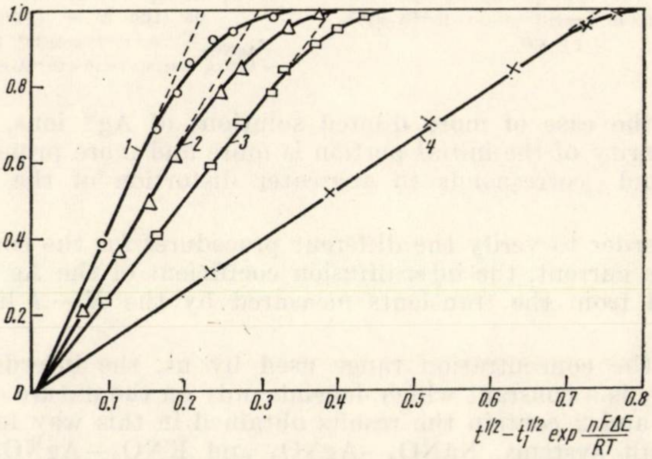

Fig. 6. — The method $E - t$ applied in the KNO_3-AgNO_3 systems.
$i = 10 \times 10^{-3}$ A·cm^{-2}; 1) $c = 0.5 \times 10^{-2}$ mole·l^{-1}; 2) $c = 0.75 \times 10^{-2}$ mole·l^{-1}; 3) $c = 1.0 \times 10^{-2}$ mole·l^{-1}; 4) $c = 2.0 \times 10^{-2}$ mole·l^{-1} $t_1 = 0.01$ sec.

On the basis of these results the following average values have been adopted:

$D_{Ag^+} = 2.54 \times 10^{-5}$ cm^2·s^{-1} in the $NaNO_3-AgNO_3$ system, and $D_{Ag^+} = 1.93 \times 10^{-5}$ cm^2·s^{-1} in the KNO_3-AgNO_3 system, at the temperature of 350°. These data are in agreement with other previously obtained results. [7] In the case of distorted chronopotentiograms, improved values of the interdiffusion coefficients are obtained.

The $8^{-\text{th}}$ column of the above tables contains the interdiffusion coefficient computed by considering only the diffusive current i_F, and leaving out the capacitive current i_c from the total current.

For a correct evaluation of the capacitive current it is necessary to know the value of the average capacity of the electrical double layer C_{dl}, which is obtained by recording the potential-time curves in the supporting electrolyte, under galvanostatic conditions.[8] Our determinations gave the following values: 120 $\mu F \cdot cm^{-2}$ in $NaNO_3$ and 100 $\mu F \cdot cm^{-2}$ in KNO_3.

An average capacitive current has been estimated by the graphical integration of equation (6) (see fig. 2).

In this way, a considerable improvement of the interdiffusion coefficients with respect to the true values is obtained (column 8), in some cases (the values marked with **) correct values of interdiffusion coefficients being obtained even from distorted chronopotentiograms.

In the last two columns of the tables 1 and 2 there are listed the relative deviations of the interdiffusion coefficient calculated after the Reinmuth's graphical method (D') and after the method suggested by us (D'').

As can be seen, by the application of two successive corrections, a considerable improvement of the interdiffusion coefficients is obtained even from the most distorted chronopotentiograms.

---

[8] R. S. Rodgers and L. Meites, *J. Electroanalyt. Chem.*, **16**, 1 (1968).

Thus, it may be concluded that the two determining processes which take place at the cathode are the diffusion and the charging of the electrical double layer.

The deviations which however exist between D'' and D_{Ag^+} can be explained by the approximate character of the expression of the capacitive current (eq. 6).

From the true values of the interdiffusion coefficients D_{Ag^+} a theoretical τ_s can be calculated for every chronopotentiogram, namely a value corresponding to the total current i.

Comparing the transient τ_s with that measured by the $E - t$ linear equation, one can estimate an experimental average capacitive current, namely

$$\frac{i - i_c}{i} = \frac{\tau_s^{1/2}}{\tau_m^{1/2}} \tag{7}$$

In the 4-th and 5-th columns of tables 1 and 2, the values of the ratio $\frac{i_c}{i} \times 100$, calculated by equations (6) and (7), are compared.

As can be seen, the experimental ratio i_c/i is twice the ratio calculated from relation (6).

Some authors have tried to correlate the value of the percent capacitive current $\frac{i_c}{i} \times 100$, with a parameter in the expression of which a term representing the electrical double layer capacity occurs. Rodgers and Meites [8] give tabulated values for the correction of the direct reading transient, depending on the different values of the quantity $\frac{C_{dl}}{i\,\tau_s}$.

Our experimental results are not within the limits set in the correction tables found in the literature, but a linear dependence between the experimental i_c/i ratio and $\frac{C_{dl}}{i\,\tau_s}$ has been noticed, as also results from fig. 7.

De Vries [6] has resolved the differential equation of diffusion depending on a so-called "distorting parameter" K, which can be defined by the expression

$$K = \frac{C_{dl} \cdot RT}{n^2 F^2 (\pi D \tau)^{1/2}\, c} = \frac{2iC_{dl}\, RT}{n^3 F^3 \pi D c^2} \tag{8}$$

Thus, the distortion of the potential-time curves owing to the double layer charging depends only upon the distorting parameter K. [6,9]

---

[9] D. Deroo, J. Guitton and J. Besson, *J. Chim. phys.*, **67**, 1097 (1970).

Other authors [10,11] have suggested that this parameter has twice the previous value, while an obvious distortion occurs for values of the parameter more than 0.001.

Taking into account the relation (1), the relation (8) can be put in the form

$$K = \frac{RT}{2nF} \cdot \frac{C_{dl}}{i\tau_s} \tag{9}$$

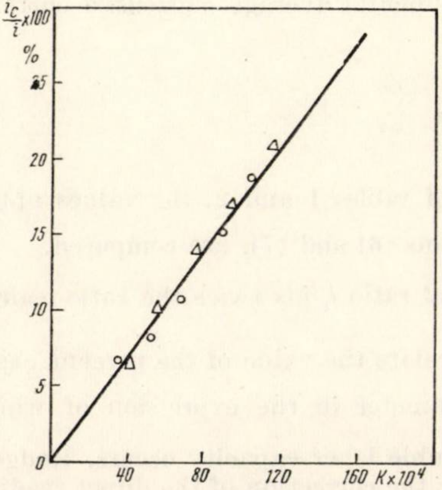

Fig. 7. — The relation between the percent capacitive current and the distorting parameter.

○ – for the $NaNO_3-AgNO_3$ systems.
Δ – for the KNO_3-AgNO_3 systems.

From the slope of the straight line represented in fig. 7, the following proportionality relation is obtained

$$\frac{i_c}{i} = 1 - \frac{\tau_s^{1/2}}{\tau_m^{1/2}} = 17.2\,K \tag{01}$$

A linear proportionality relation between $\frac{i_c}{i}$ and K can be also deduced from relation (6).

Putting in this last relation $t = \alpha \cdot \tau$, we obtain

$$\frac{i_c}{i} = \frac{RT}{2nF} \frac{C_{dl}}{\beta i \tau_s} \tag{11}$$

where $\beta = \alpha^{1/2} - \alpha$.

---

[10] M. L. Olmstead and R. S. Nicholson, *Analyt. Chem.*, **42**, 796 (1970).
[11] O. Dracka, *Coll. Czech. Chem. Comm.*, **34**, 2627 (1969).

Fig. 8 shows the variation of β as a function of the ratio $\alpha = \frac{t}{\tau}$. By graphical integration and averaging, we obtain for the mean value $\bar{\beta} = 0.14$.

Substituting this in relation (9) we obtain

$$\frac{i_c}{i} = 7.1\,K \tag{12}$$

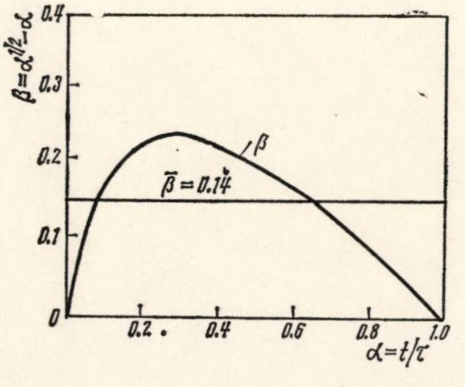

Fig. 8. — The dependence of β on the ratio $\alpha = t/\tau$.

As can be seen, the computed proportionality factor is approximately one half of that obtained from relation (9), which has been determined from experimental data. The disagreement results from the approximate character of the equation (6) in which the current i and, consequently, the transient τ_s have been considered constant.

The correction of the capacitive current, using the method suggested by De Vries, requires a very complicated computation to complete the correction tables.

The semi-empirical relation (10) proposed by us can be used for a direct correction of the capacitive current.

From the experimental data obtained by us, it also follows that under certain conditions of concentration and current densities (when the ratio $\frac{C_{dl}}{i\tau_s}$ is low), one obtains "quasi-ideal" chronopotentiograms, to which the Reinmuth's graphical method can be successfully applied, for a correct calculation of the transients and of the interdiffusion coefficients in molten salts.

STUDY OF ELECTROCHEMICAL FORMING OF SURFACE OXIDES ON THE ACTIVE CARBON ELECTRODE

OV. MATEIOVICI

Military Academy,
Şos. Panduri 60, Bucureşti, Romania

Received June 15, 1972

The formation of oxides compounds on active carbon electrode was investigated by means of the charging curves method. After a previous cathodic polarization up to zero value of the potential, the electrode was anodically polarized with a current of 90 μ amp (that is 7.5×10^{-9} amp/cm^2) up to the potential of + 1,200 mvolts (*vs.* normal hydrogen electrode). From the form of the charging curve, the presence of two oxide types was ascertained, but their structure was not determined. No influence of the chemisorbed gases, such as AsH_3, on the surface of the electrode was observed. The form of the charging curves is strongly dependent on temperature. Thus, the amount of oxygen which can be desorbed increases with temperature. On the basis of this phenomenon, the active electrochemical oxygen concept was introduced for the case of an active carbon electrode. From this point of view, the same potential of the active carbon electrode is expressed as different amounts of oxygen for constant pH and temperature values.

The electrochemical phenomena of the active carbon are based on the potential difference existing between surface oxides (the combinations *in situ* of carbon with oxygen) and the electrolyte solution. These surface oxides are not so well defined. They depend on many factors, that is : the raw material of the active carbon, its treatment both during activation and post-activation and so on.

Generally speaking, one can distinguish between three forms of oxygen sorption : physically adsorbed oxygen, chemically adsorbed oxygen and chemisorbed oxygen. The ratio between these three forms of oxygen lies in the same factors mentioned before.

Austen and Ingram[1] established, by the paramagnetic resonance method, that free radicals form on the surface of the active carbons. Garten and Weiss [2] state that on the surface of different carbons there are quinone and hydroquinone groups. Active carbons which have an intermediary structure between quinone and hydroquinone must be assumed. [2]

---

[1] I. Austen and A. Ingram, *Chem. and Ind.*, **37**, 981 (1956).

[2] S. Garten and W. Weiss, *Austral. J. Chem.*, **8**, 68 (1955).

By infrared spectroscopic method, hydroxyl and carbonyl groups were detected as a result of the reactions between O_2, O_3 and H_2O and active carbons. [3-5] Between the activation temperature and the properties of the active carbons, a strong relationship was observed. [6] But not all carbon-oxygen compounds are active in oxidation reactions.

Rideal and Wright [7,8] pointed out that oxidation action is not due to the oxygen found in the stable oxides form.

Davtian and co-workers [9] showed that in SO_2 oxidation, on the surface of the active carbons, take part some surface oxides which are easily desorbed at the room temperature and in vacuum.

Frumkin [10] and later Davtian [11] investigated the surface compounds on the active carbon electrode by means of the charging curves.

In the present work, new aspects regarding surface oxides forming are emphasized.

EXPERIMENTAL TECHNIQUE

In this work an active carbon electrode made by wood char was used. The mass of the electrode was small and varied between 1.5—1.7 mg. The electrode was completely immersed into solution. The cell made of glass, was closed and thermostated. As a comparison electrode, the calomel electrode was used and the potentials were referred to normal hydrogen electrode.

The electrochemical forming of surface oxides was studied by means of the charging curves method.

The electrolyte was 0.02 M. H_2SO_4 solution. For the preparation of the solution, twice-distilled water was used.

EXPERIMENTAL RESULTS

1 — The chemisorbed oxygen amount can be determined from the length of the charging curve. The charging curve was taken by cathodic polarization with a current of 3 μ amp starting from the steady potential (+650 m volts) up to zero value. The temperature was 25°. Inasmuch, as the specific area of the electrode was 1.2 m^2, a current density of 2.5×10^{-10} amp/cm^2 results.

The form of the charging curve is represented in figure 1.

Taking into account the adsorption pseudocapacitance it results an amount of chemisorbed oxygen of 500 μ equivalents/g. From the fact that on the charging curve, two distinct regions characterized by two flats can be seen: one of them at the potential of +570—580 m volts, which lies on 8—10 m coulombs, and the other, at the potential of about 300 m volts, which lies on about 40 m coulombs, would suppose that two individual oxides exist here.

2 — The electrode was purified of oxygen for six days, by cathodic polarization up to zero potential. The polarization was made with a current of 3 μ amp. Onto the electrode, N_2 free oxygen was bubbled for a few hours. The charging curve was taken at the current of 90 μ amp and 25° temperature.

Both during cathodic polarization, that is for oxygen desorption, and during the drawing of the charging curve, high purity AsH_3 was bubbled onto the electrode for a few minutes. When the potential was + 1,200 m volts, the current was switched off and inverted for oxygen desorption up to zero potential value and then a new charging curve was drawn. Three similar curves were obtained and their aspect is shown in figure 2. Two distinct domains on the charging curves are distinguished: first a linear portion up to about + 1,000 m volts, and the second, a flatter portion over + 1,000 m volts.

No effect by bubbling AsH_3 onto electrode was observed in what concerns the length and the form of charging curves.

3 — To investigate the variation of the charging curves form with temperature, in figure 3 two curves at + 5° are plotted. As can be seen, for the small temperature, the reproductivity between two determinations is better. Also, for the small temperature the charging curve begins to incline for a greater potential.

4 — It is of interest to know in what way the oxygen could be desorbed from the electrode surface at once after its chemisorption. The same current of polarization as above was used both for anodic and for cathodic polarization 90 μ amp (Fig. 4).

The working temperature was 25°. In this case, half a quantity of electricity necessary for obtaining the potential of + 1,200 m volts is used to get up to zero potential.

Another question in connection with the quantity of oxygen maintained as electrochemical active oxygen was focused by the next experience. Thus, for the temperature of + 7°, 35 μ coulombs/cm^2 are necessary up to zero potential, while for the temperature of + 25°, 52 μ coulombs/cm^2 are necessary. Two curves (potential vs. quantity of electricity) are plotted in Figure 5.

5 — To detect some disturbance regarding the charging curve with time, the electrode was polarized with a cathodic current of 3 μ amp for 15 days. For this current a very stable zero dynamic potential was obtained. After the electrode was purified in this way, two charging curves were taken for two temperatures: +7° and +25°. In this case, in spite of the fact that the purification time of the electrode by polarization varied in large limits, no discrepancy between the length and the

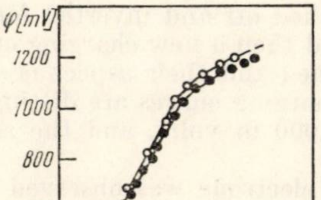

Fig. 3. — Charging curves of the active carbon electrode ($T = 5°$).

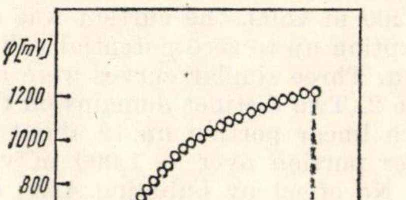

Fig. 4. — Anodic (above) and cathodic charging curves of the active carbon electrode.

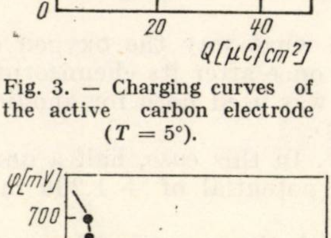

Fig. 5. — Variation of the potential, at the oxygen desorption, with the quantity of electricity at the temperatures of 25° (curve *1*) and of 7° (curve *2*).

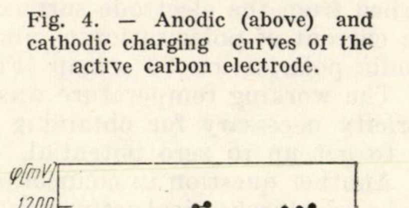

Fig. 6. — Form of the charging curves after a cathodic polarization of the electrode for 15 days, up to zero value of potential at the temperature of 25°, (curve *1*) and at the temperature of 7° (curve *2*).

form of the charging curves were observed as visible in figure 6, by comparison with the curves given in figures 2 and 3. From this fact, an independence of the form of the charging curves on the time results.

DISCUSSION AND CONCLUSIONS

It is beyond any doubt that the electrochemical phenomena investigated on the active carbon electrode are based on the active surface compounds. It is very difficult, if not impossible, to define all compounds existing between some intervals on the charging curve and, therefore, no effort in this respect was made in the present work.

However, some assurances were established.

Thus, the amount of oxygen, which may be electrochemisorbed on the electrode here investigated, is always the same for the same current value. It can be imagined that on the other active carbon electrode (i.e. coconut shells) the amount of electrochemisorbed oxygen could be different. The form of two charging curves showed a better reproductivity for the curves taken at the lower temperature.

This is probably due to a better definition of the surface oxides. It is interesting to note that no effect was observed if on the surface of the electrode other gases (i.e. AsH_3) are chemisorbed.

In other words, it seems that the surface of the active carbon electrode is characterized by two areas : an active electrochemical area and a chemical area. No interference between these two areas was observed for this electrode.

A remarkable fact lies also in the independence of the length and the form of the charging curve on the cathodic polarization time up to zero dynamic potential value. This phenomenon proved that a limit time exists in the purification of the electrode, beyond which, the time (hence, the quantity of electricity) is ineffective.

By polarization of the electrode with a small current which varies from 1×10^{-9} amp to 3×10^{-6} amp, the electrode potential deviates from the value of the steady potential, function of the current polarity. If the current is maintained between these limits and is kept rigorously constant, the potential is established at one value which persists as long as the electrode is polarized.

This potential was named the "dynamic potential".

The dynamic potential is very constant provided that both pH and temperature are constant.

However, if one proceeds to the interruption of the cathodic polarization current, the dynamic potential fades away and the steady potential is established again. The steady potential of the active carbon electrode, in 0.02 M. H_2SO_4 solution, is $+650-750$ m volts. (*vs*. the normal hydrogen electrode).

From the fact that the electrode may get up to the same potential but with different amounts of oxygen, depending on the temperature, proves that only a part of the oxygen is electrochemically active. The rest has no importance from the electrochemical point of view. Unfortunately, it is difficult to find a rigorously mathematical relation between the potential and the electrochemically active oxygen concentration (for given pH and temperature values).

The charging curves method pointed out the complexity of the phenomenon, giving some information with respect to the state of the surface.

STOCHASTIC MODELLING OF CHEMICAL PROCESSES

O. IORDACHE, MARCELA MUNTEAN and I. TEOREANU

Polytechnic Institute, Str. Polizu 1, Bucharest, Romania

Received July 17, 1972

In the present paper a general mathematical model for the irreversible evolution in discrete stages of some chemical processes is presented. The model is adapted for the hardening process of silicate binders. A good concordance with the experimental results is obtained.

1. INTRODUCTION

The evolution of chemical processes is often essentially influenced by a great number of factors having as result a probabilistic comportment. Consequently, to describe such processes, stochastic models are recommended instead of deterministic ones.

The advantages of stochastic models result mainly from their congruence with the intimate mechanism of the process development. Sometimes, the results obtained with stochastic models can also be found by deterministic models, but the considerations regarding the development of the process as a whole and in large intervals of time, as are usually done for deterministic models, often hinder even the essence of the studied phenomena. The stochastic models give also, along with the average values of the parameters, the differences from these values. The stochastic models use statistical parameters obtained directly from experiment or intuitively chosen when the difficulties do not permit to explain the cause of a certain comportment of the phenomenon but the necessities impose the knowledge of the concrete mode of the process development.

The stochastic models are important for the study of some problems, for example : the kinetics of chemical reactions (i.e. autocatalytic, chain reactions and especially polymerization ones), the structure formation of certain materials (coagulation, restructuring, felting of polymers, hardening of binders, fatigue of materials), transport phenomena (mass, heat, momentum), growth phenomena (crystallization, coalescence, etc.).

In the present paper a general mathematical model for the irreversible evolution, in discrete states, is presented. A discussion of the way in which, depending on the process, the necessary statistical parameters are chosen, as well as the way of interpreting the process according with the particular values of the parameters. The models are then applied for the hardening of the constituents of portland cement clinker and especially for the hardening of tricalcium silicate.

2. MATHEMATICAL MODEL

Let us denote by $X(t)$ the stochastic variable with discrete values $1, 2 \ldots n$, representing the evolution step of the process (e.g. the polycondensation degree), by $P_{ij}(\tau, t)$, the transition probability defined as

$$P_{ij}(\tau, t) = \text{Prob}\,\{X(t) = j \mid X(\tau) = i\}\ (t \geqslant \tau \geqslant 0)$$

(the probability that the polycondensation degree at time t to be j, if, at the previous time τ, it was i), by $q_i(t)$ the intensity function defined as

$$q_i(t) = \lim_{\Delta t \to 0} \frac{1 - P_{ij}(t, t + \Delta t)}{\Delta t}$$

(the probability that the polycondensation degree $X(t)$ to change in the interval $(t, t + \Delta t)$ is $q_i(t)\,\Delta t$, if at time t, it was i), by $Q_{ij}(t)$, the probability of relative transition defined as

$$q_i(t)\,Q_{ij}(t) = \lim_{\Delta t \to 0} \frac{P_{ij}(t, t + \Delta t)}{\Delta t}$$

(conditional probability that the polycondensation degree to become j at time $(t + \Delta t)$, if it has been i, at time t and in the interval $(t, t + \Delta t)$ it has changed).

The aim of this paper is to determine the transition probabilities $P_{ij}(\tau, t)$ which actually offer concrete values for the fraction of the substance arrived in the state j, at time t, if at the previous time τ, it has been in the state i.

Making the hypothesis that the successive changes are independent (Markov process, without memory), the probabilities follow the Kolmogorov-Feller's equations [1]

$$\begin{aligned} \frac{\partial P_{ij}(\tau, t)}{\partial t} &= -\,q_i(t)\,P_{ij}(\tau, t) + \sum_{k=0}^{\infty} q_k(t)\,Q_{ij}(t)\,P_{ik}(\tau, t) \\ \frac{\partial P_{ij}(\tau, t)}{\partial \tau} &= q_i(\tau)\left[P_{ij}(\tau, t) - \sum_{k=0}^{\infty} Q_{ij}(\tau)\,P_{kj}(\tau, t)\right] \end{aligned} \qquad (1)$$

---

[1] W. FELLER, "An introduction to probability theory and its applications", vol. I., second ed., Academic Press, New York, 1960.

In the particular case of the polycondensation process by successive adding of monomer units, the equations (1) become

$$\frac{\partial P_n(t)}{\partial t} = -\lambda(n, t)\, P_n(t) + \lambda(n-1, t)\, P_{n-1}(t). \tag{2}$$

In Eq. (2) $\tau = 0$, $i = 1$ was considered as initial state (that is, the polycondensation process starts from the monomer) and the following notations were made

$$q_n(t) = \lambda(n, t)$$

$$P_{1n}(0, t) = P_n(t).$$

$P_n(t)$ represents the probability that the polycondensation degree be n at time t, if initially it was 1 ; actually, as in the polydisperse silicate systems, the number of particles is practically great, $P_n(t)$ represents also the fraction of the n-silicate in the mixture.

Equation (2) shows that the variation in time of the quantity of n-silicate at time t, $\frac{\partial P_n(t)}{\partial t}$ is due to the decrease of the n-silicate, $-\lambda(n, t)\, P_n(t)$, as a result of the reaction with intensity $\lambda(n, t)$ by which this n-silicate becomes $(n+1)$-silicate, as well as by the increase of the quantity of n-silicate, $\lambda(n-1, t)\, P_n - 1\,(t)$, due to the reaction of $(n-1)$-silicate which, with the intensity $\lambda(n-1, t)$, becomes n-silicate at time t.

The model described by (2) is connected with a given phenomenon by the parameter $\lambda(n, t)$, that is by the particular way by which the change intensity depends on the polycondensation degree at time t. The justification of the dependence is found in the mechanism itself, and it is, at the same time, an explanation of the mechanisms proposed to explain some experiments. The parameter $\lambda(n, t)$ is analogous to the rate constants of the processes used in deterministic treatment (for example in the chemical kinetics). This parameter appears as a synthetic indication of this process evolution. It constitutes a powerful tool, permitting the expression, of some different and complicated phenomena, in a working manner, using simple and intuitive equations like equation (2). It must be mentioned that, due to its character of statistical estimator, it avoids sometimes the explanation of the physicochemical process.

In what follows, some particular cases of dependence of parameter λ on the polycondensation degree n and the time t will be analysed.

Case 1. (C_1) The intensity function of the transition is constant $\lambda(n, t) = \lambda$.

This is the hypothesis of equal reactivity. The rate constant of the polycondensation process remains constant throughout the process evolution. This hypothesis was used by Flory [2] in the case of polycondensation by addition without termination.

From the physical point of view this hypothesis is connected with the invariance of the electronic structure of the functional groups with the increase of n, with the absence of steric hindrance, and with the fact that in the system the only process taking place is the polycondensation. In the case of the hardening of silicate binders these assumptions do not hold; here the steric and spatial hindrances, which appear as the silicate chains grow and the hardening process develops, led to a decrease of λ with n, while the process of formation of hardened structure determines a slowing in time of the polycondensation process.

For the assumption of equal reactivity the distribution of n-mer is of Poisson type. From (2) one obtains

$$P_n(t) = \frac{(\lambda t)^{n-1}}{n!} e^{-\lambda t}. \tag{3}$$

This distribution is suited to a good description of a simple phenomenon like vinyl polymerization. The polycondensation process of calcium silicates, due to the above reasons is not governed by (3), except for small times. The distribution (3) shows a decrease of the monomer quantity in time and an increase followed by a decrease and then by an asymptotic stabilization of the quantity of dimer, trimer etc.

Case 2 (C_2). The intensity function depends on state and does not depend on time: $\lambda(n, t) = \lambda(n) = \lambda n$.

In this case the reactivities of the mers are different for different states but are independent on time. It means that some motives appear in the system for the variation of the transition intensity with the state of the system (modifications due to the conjugation of the electronic structure, steric hindrance etc.) but there are not other phenomena superimposed on those studied.

The distribution of the n-mer in time is

$$\begin{cases} P_n(t) = \beta_n \sum\limits_{k=1}^{\infty} \dfrac{1}{\alpha_{nk}} e^{-\lambda n t} \\ \\ P_1(t) = e^{-\lambda_1 t} \end{cases} \tag{4}$$

where

$$\alpha_{nk} = \prod_{\substack{i=1 \\ i \neq k}}^{n} \gamma_{ik} \qquad \text{for } K \leqslant n,$$

and

$$\gamma_{ik} = \lambda_i - \lambda_k$$

---

[2] J. P. Flory, "Principles of polymer chemistry", Cornell University Press, Ithaca, New York, 1953.

These equations maintain the general characteristics of the Poisson distribution (to which the distribution given by (4) tends, when $\lambda_i = \lambda =$ constant) but (4) is more comprehensive because it permits to describe some phenomena for which the evolution from a state to another determines essential changes.

The result is useful for the study of the kinetics of some consecutive reactions. It may characterize, for example, a phenomenon like the condensation of the silicic acid. The polycondensation of the hydrated calcium silicates can not be described by (4), but only at small times of hardening, when the parallel structuring phenomena have not a great development.

Case 3 (C_3). The intensity function depends only on time not on state $\lambda(n, t) = \lambda(t)$.

Such a dependence may appear when in a system, like in C_1, different phenomena take place; for example if the polycondensation or polyaddition reaction of some simple substances is controlled by diffusion, then the effect of the diffusion is manifested by a particular dependence on the time of the parameter λ. Sometimes a strong dependence on time may hide a weak dependence on n.

In the case of cooling the silicate glass, for which the polymerization process was often treated in the C_1 hypothesis, the dependence on time may appear when the polycondensation of silicates is accompanied by solidification.

The distribution of the n-mer is

$$P_n(t) = [1 - \beta(t)]\,[\beta(t)]^{n-1} \tag{5}$$

where

$$\beta(t) = 1 - e^{\gamma(t)}$$

and

$$\gamma(t) = -\int_0^t \lambda(\tau)\, d\tau$$

This distribution maintains the general characteristics of the distributions obtained in C_1 and C_2, that is, the decrease in time of the quantity of the monomer and the increase, followed by the decrease and the stabilization of the polymer quantity.

In the case of the hardening of the silicate binders where the formation of the hardened structure leads to a very strong dependence on time of the polycondensation rate, the above distribution may represent a rather good approximation, especially when the number of the functional groups, — OH, is constant.

Case 4 (C_4). The intensity function depends both on time and state.

This situation corresponds to the case of inequal reactivity and superposition of phenomena in the system. This is the most complicated situation, from the mathematical point of view but is the situation most often found in practice.

In this case, the main problem is to define, using a qualitative description of the phenomena and the experimental facts, the dependence of the parameter λ on time and degree of polycondensation.

The hardening of the silicate binders, particularly of the tricalcium silicate, results from a partial superposition of three processes : the hydration — hydrolysis of the binder with the formation of gelic calcium hydrosilicates and the coagulation of these hydrosilicates, the polycondensation and crystallization of the formed calcium hydrosilicates and the formation of the hardening structure.

These three phenomena superpose one another in such a way that the polycondensation (which is preceded, at molecular scale, by hydration — hydrolysis process and followed by structuring) can be characterized only by an intensity function, dependent on time and degree of polycondensation.

The dependence on the polycondensation degree is explained by steric hindrance, by a possible modification of the number of functional groups, by the inclusion in the hardened structure of molecules with high polycondensation degree, by the appearance of cyclic polymers, etc.

The dependence on time may be explained by the strong decrease of the reaction rates due to the development of the hardened structure which strongly hinders the phenomenon.

The polycondensation is characterized by two statistical parameters : β, the fractional decrease of the intensity of the process for an increase with a unity of the polycondensation degree, at constant time, and γ, the fractional decrease of the intensity of the process in a unit time, at a constant degree of condensation

$$\beta = -\frac{1}{\lambda}\left(\frac{\partial \lambda}{\partial n}\right)_t$$

$$\gamma = -\frac{1}{\lambda}\left(\frac{\partial \lambda}{\partial t}\right)_n \qquad (6)$$

The above relations show that the variation in time and with the polycondensation degree of λ is so much the bigger, the bigger is λ. Therefore, the more rapid processes decay rapidly and the slow ones decay slowly.

The use of these parameters is based on the assumption, confirmed by experience, that a particular pair of values of β and γ characterize a certain binder (for example $3\ CaO.SiO_2$). It results, therefore, that β and γ depend on the nature of the substances present and depend very little on time and on polycondensation degree. This very property imposes and permits their use.

With β and γ defined by (6) it results

$$\lambda(n, t) = e^{-\beta n} e^{-\gamma t} \tag{7}$$

The solution of the equation (2) is therefore

$$P_n(t) = e^{-\int_0^t \lambda(n,t)\mathrm{d}t} \int_0^t \lambda(n-1, t) P_{n-1} e^{\int_0^t \lambda(n,t)\mathrm{d}t} \mathrm{d}t \tag{8}$$

3. COMPARISON WITH THE EXPERIMENT

The above result is compared to the results obtained by Lentz.[3] A good correlation is obtained using for β and γ the values of 2/3, respectively 1/3, that is for an increase by a unity of the polycondensation degree λ decreases by 66 % of its value and for a unit time elapse λ decreases by 33% of its value. Therefore, the dependence of λ on n and t is very strong and this is due especially to the structuring phenomena which hinder the polycondensation. The intensities of the transition vary so much with n and t, that for a certain n, the advance of the polycondensation is unlikely to vary (and this is one of the reasons that the presence of high n-hydrosilicates is not found in the experiment); experimentally, values of the order of tenths are obtained for n, and for a certain time, the reaction is practically stopped. This situation corresponds to that found in reality, where after 1–3 months the polycondensation reactions practically do not advance any more.

With the above values for β and γ and using the graphical integration the results shown in table 1 for 3 $CaO.SiO_2$ are obtained :

Table 1

The distribution of hydrosilicates

Time	1 day	7 days	28 days	3 months	4 years	14.7 years
Hydromonosilicate-$P_1(t)$	65	27	23	22	21.5	21
Hydrodisilicate-$P_2(t)$	17	30	34	34	33.2	33
Hydrotrisilicate-$P_3(t)$	2	7	7.5	7.2	7	7

The comparison with the experiment shows a good concordance up to 3 months of hydration time (fig. 1). For larger periods of time the concordance is weaker; the fact may be due to the structuring phenomena which take away variable quantities of n-hydrosilicate from the reaction medium.

---

[3] G. Lentz, "Symposium on structure of portland cement paste and concrete", Academic Press, Washington, 1966.

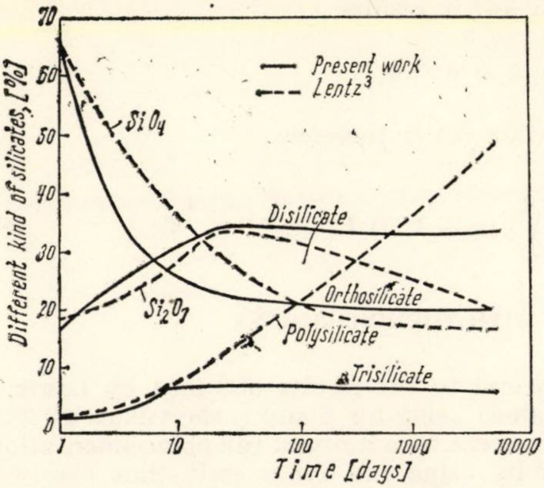

Fig. 1. — The concentration of polysilicates in tricalcium silicate pastes.

The present stochastic model, which can be applied to the hardening of silicate binders, makes evident two statistical parameters β and γ. Their systematic study for different binder classes may be useful. These parameters characterize, from the polycondensation process point of view, the nature of the binder and the nature of the substances present in the binder mass (ions, etc.).

NEW URANYL COMPOUNDS WITH PYRIMIDINE DERIVATIVES

FLORICA POPEA, CRISTINETA MĂRCULESCU and CONSTANŢA PÎRLOG

Centre of Physical Chemistry, Str. Dumbrava Roşie 23, Bucharest, Romania

Received July 4, 1972

In this paper, 3 new uranyl compounds of the general formula $ML_2 \cdot nH_2O$ are presented ($M = UO_2$; $L =$ barbituric acid, thiobarbituric or 5-ethyl-barbituric acid). They are characterized by thermal behaviour, X-ray diffraction studies, u.v. and visible reflectance spectra, as well as i.r. vibration spectra.

In a previous paper, a spectrophotometric study on the behaviour of the uranyl ion, in the presence of barbituric (AB) and thiobarbituric (ATB) acid, in aqueous, ethanol, methanol and acetone solution was reported.[1]

In this work, some new, solid compounds obtained in the reaction of the uranyl ion with the same reagents, are presented. Having in view the reactivity of the position 5 and the tautomery involved for the hydrogen atoms in the positions 1,3 of the pyrimidine ring,[2,3] researches concerning the reaction of the uranyl ion with some 5-substituted derivatives of the barbituric acid, were also performed. Both 5-bis-substituted derivatives (5,5-phenyl-ethyl-barbituric and 5,5-diethyl-barbituric acid) did not allow to obtain a compound. With alloxan, although it includes a high reactive CO in the position 5, presumably undergoing an oxido-reduction reaction in aqueous solution, no unitary compound was obtained.[4]

Considering that the presence of a free hydrogen atom at the C_5 prompts the reactivity of the ligand towards the metallic ion, we managed syntheses with monosubstituted derivatives of the barbituric acid, namely with 5-aminobarbituric, 5-nitrosobarbituric (violuric), 5-nitrobarbituric (dilituric) and 5-ethylbarbituric acid. In the reactions of the 5-amino-, 5-nitroso- or 5-nitro-barbituric acids with uranyl ion, no unitary solid product was obtained, although, both with violuric [5,6] and dilituric acids[7-10] unitary, solid compounds with numerous metallic ions have been quoted in the literature, some of these reactions providing gravimetric methods used in the determination of these ions. Microscopic studies are also reported on the crystals obtained in the reaction between the uranyl ion and the violuric acid. [11] Only 5-ethyl-barbituric acid (5-EB) leads to the formation of an uranyl compound of the same type as those of the barbituric and thiobarbituric acids ones, suggesting the presence of the ethyl radical in C_5 to promote the labilization of the neighbouring hydrogen atoms.

These would be consistent with the failure to obtain solid, unitary compounds in the reaction of the uranyl ion with the barbituric acids nonsubstituted in C_5, but substituted in the 1 (1-phenylbarbituric acid) and 1,3 positions (1,3-biphenylbarbituric acid).

The compounds obtained are of the $ML_2.nH_2O$ type ($M = UO_2$, L = AB, ATB, or 5-EB) and were synthesized using the direct reaction, in aqueous solution, of stoichiometric amounts of the uranyl nitrate hexahydrate towards the respective acid, respecting severely the conditions indicated.

EXPERIMENTAL

STARTING MATERIALS

The following reagents were graded and used without additional purification:

$UO_2(NO_3)_2 \cdot 6H_2O$ ANALAR; barbituric acid. $2H_2O$ Carlo Erba; Alloxan—Chinoin; 5-nitrobarbituric (dilituric) acid, 5,5-diethyl-barbituric acid and 5,5-phenyl-ethyl-barbituric acid — E. Merck; 5-aminobarbituric and 5-nitrosobarbituric acid — Fluka. The following ones were synthesized and purified in the laboratory by methods reported in the literature: thiobarbituric acid, [12] 5-ethyl-barbituric acid, [13] 1-phenyl-barbituric acid and 1,3-biphenyl-barbituric acid. [14]

SYNTHESIS OF THE COMPOUNDS

$UO_2[AB]_2 \cdot 4 \cdot H_2O$ (I) An aqueous suspension of 0.002 M AB·$2H_2O$ was treated with dilute NaOH to give the pH=5.4 (the final volume not exceeding 30 ml) and heated to 75—80°. 0.001 M solid uranyl nitrate was added, stirring vigorously and keeping the same tem-

perature for about 5′; the solution turned turbid. On cooling at room temperature, a bright yellow precipitate separated, which was filtered after about 30′, washed with 10 ml 50% ethanol (aqueous solution) and air dried.

$UO_2[ATB]_2 \cdot 5H_2O$ (II) 35 ml warm water (70–75°) was poured over 0.002 M ATB and a fairly clear solution was obtained; then, 0.001 M solid uranyl nitrate was added warming with agitation at the same temperature for other 5′. The solution turned brown, became gradually yellow and on cooling at room temperature the separated orange yellow precipitate was filtered after about 30′, washed and dried like the compound (I).

$UO_2[5\text{-}EB]_2 \cdot H_2O$ (III). A mixture of 0.002 M 5-EB and 10 ml water ($pH = 2.8-3$) was treated with diluted NaOH to reach $pH = 3.4$ and warmed at 60–65°. Then 0.001 M uranyl nitrate was added, stirred vigorously and continually heated at the same temperature for other 5′. The solution, red-coloured on the addition of the uranyl nitrate, changed gradually to yellow, then following the separation of the orange, crystalline precipitate. After cooling at the room temperature and settling (for about 30′) the product was filtered, washed with cold water (+4°) and air dried.

The composition of the 3 new compounds was established on the basis of the chemical analysis, (the analytical data and their colour are summarized in table 1) namely: the metal was determined as oxide (U_3O_8) by ignition, while nitrogen, carbon and hydrogen by microcombustion.

Table 1

Analytical data

Compound	Colour	U%		C%		H%		N%	
		calcd.	*found*	*calcd.*	*found*	*calcd.*	*found*	*calcd.*	*found*
(I)	canary-yellow	39.92	40.23	16.48	16.61	2.54	2.48	9.39	9.47
(II)	yellow-orange	36.94	36.96	14.91	14.92	2.50	2.48	8.66	8.50
(III)	orange	39.18	39.32	24.42	24.20	2.70	3.08	9.29	9.51

The shining microcrystals of (I), (II) and (III) are stable at room temperature, but decompose on heating. They are practically insoluble in common solvents (water, ethanol, methanol, acetone, ether, CCl_4, TBF, THF, DMSO, DMF, ethyl acetate, benzene) and only sparingly soluble in warm water. The compounds were characterized by thermal studies, by X-ray diffraction studies, electronic and i.r. spectra.

APPARATUS

The thermal studies were performed by means of a MOM E. Paulik, J. Paulik-L. Erdey Derivatograph and by using the Boetius heat table. The X-ray diffraction patterns were recorded on the URS. 50. IM equipment; the intensity data were collected on a diffractometer with Geiger–Müller counter. The reflectance spectra were drawn on a VSU-1 C. Zeiss-Jena spectrophotometer and the i.r. spectra were recorded on a UR-20 C. Zeiss-Jena spectrophotometer.

RESULTS AND DISCUSSION

Thermal behaviour. In order to determine the number and the bonding of the water molecules in the new compounds, the thermal curves were recorded in the 30°—300° temperature range with a 5°/min. rate, in air atmosphere, using Al_2O_3 as standard. An amount of 0.4—0.5 g was taken for each sample.

The TG and DTG curves (fig. 1) indicate for the compound (I) a 11.31 % loss of weight between 150° and 230° corresponding to $4.H_2O$ for a molecule of anhydrous compound, followed by a weak slope. The DTA curve reveals at 155° the starting of a transformation with endothermic effect, its maximum value, at 210°, corresponding to the removal of the crystallization water.

The TG and DTG curves in fig. 2 evidence a smooth decrease of the weight, beginning with 60°. Between 90° and 130°, the water is expelled with an increased rate, the 11.22 % loss of weight corresponding to 4 water molecules. The following 2.75 % loss of weight, between 130° and 210° is developed with a smoother slope and corresponds to the removal of another water molecule. Starting with this temperature, the horizontal level appears, which characterizes an anhydrous compound. The DTA curve reveals an endothermic, striking effect, between 100° and 130°, with a maximum at 100°, and another one much weaker between 190° and 230° with a maximum at 208°. As can be seen, the thermal curves allow to conclude that one of the 5 water molecules is differently bound in the compound.

For (III) like for (II), the thermogravimetric analysis indicates a slight loss of weight (4 %) between 100 and 280°. The endothermic effect corresponding to the removal of the water is very weak with a maximum only at 185°.

As can be seen in table 2, the values obtained for the crystallization water, by means of the thermogravimetric analysis, agree with those calculated on the basis of the chemical data.

Table 2

% crystallization water content

Compound	% water content	
	Calculated on analytical data	Found by thermogravimetric analysis
(I)	12.08	11.31
(II)	13.97	13.97
(III)	3.01	4.00

In addition, the thermal behaviour of the compounds was also followed with a Boetius heating plate.

Starting with 140°, compound (I) presents some modifications, which reach a maximum effect at 200°—220°. At 265°—300° the product undergoes decomposition.

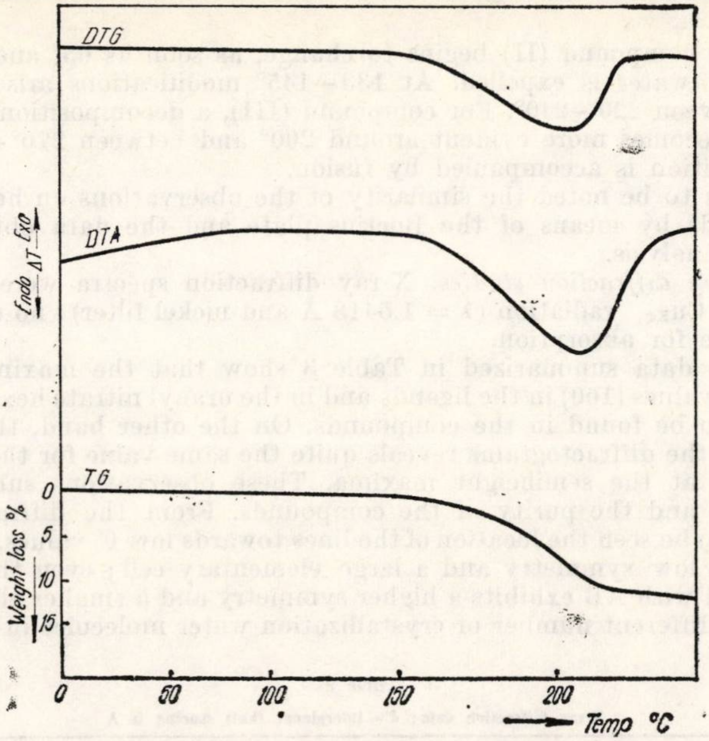

Fig. 1. — Thermal curves for $UO_2\,[AB]_2 \cdot 4H_2O$ (I).

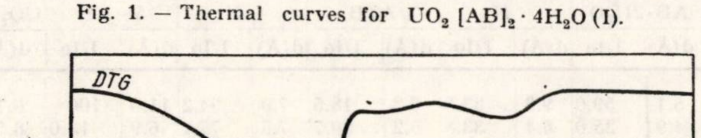

Fig. 2. — Thermal curves for $UO_2\,[ATB]_2 \cdot H_2O$ (II).

The compound (II) begins to change, as soon as 65° and between 104—115° water is expelled. At 133—145° modifications arise, emphasized between 220—240°. For compound (III), a decomposition observed at 140° becomes more evident around 200° and between 270°—300° the decomposition is accompanied by fusion.

It is to be noted the similarity of the observations on heating the compounds by means of the Boetius plate and the data obtained by thermal analysis.

X-ray diffraction studies. X-ray diffraction spectra were recorded using the $Cu_{K\alpha_1}$ radiation ($\lambda = 1.5418$ Å and nickel filter); no correction was made for absorption.

The data summarized in Table 3 show that the maxima of the intensity values (100) in the ligands and in the uranyl nitrate hexahydrate, are not to be found in the compounds. On the other hand, the examination of the diffractograms reveals quite the same value for the breadth measured at the semiheight maxima. These observations substantiate the unity and the purity of the compounds. From the diffractograms it is also to be seen the location of the lines towards low θ° values, accounting for a low symmetry and a large elementary cell; even though the compound with AB exhibits a higher symmetry and a smaller elementary cell. The different number of crystallization water molecules in the com-

pounds evidence the fact that they do not belong to the same structure type, as a consequence of the lack of isomorphic relations.

Electronic spectra. The reflectance spectra were drawn at room temperature within 260 nm (38,461 cm^{-1}) — 1200 nm (8,333 cm^{-1}) range, using MgO as standard.

Figures 3, 4, and 5 show that the absorption bands proper to the uranyl ion appearing at 410 nm (24,390 cm^{-1}) and 315 nm (31,740 cm^{-1}) are assigned to the transition $^1\Sigma_g^+ \rightarrow {}^3\pi_u^-$, respectively $^1\Sigma_g^+ \rightarrow {}^1\Sigma_u^-$ or $^1\Delta_{2u}$.[15]

As far as the absorption maxima of the ligands are concerned, they appear in the u.v. range at about 300 nm (30,303 cm^{-1}) and can be ascribed

to a transition n → π* from the nonbonding orbital of the nitrogen to the π antibonding orbitals of the pyrimidine ring. [16] The other absorption maxima in the region 430 nm (23,255 cm^{-1}) — 450 nm (22,200 cm^{-1}) could be ascribed to the presence of the substituents in the pyrimidine ring.

As can be seen, the shape of the absorption curves of the compounds present the maxima proper to the ligands, as weak inflexions. *Infrared spectra.* The i.r. spectra were recorded within the 400—1800 cm^{-1} range, using solid substances pelleted with KBr and they are given in table 4.

[16] J. P. Phillips, "Spectra-Structure Correlation" Academic Press, New York, London, 1964, p. 114—120; 152—155.

The uranyl ion, with an almost linear arrangement of the chemical bonds $O{=}U{=}O$, presents an absorption maximum in the 930–960 cm^{-1} range,[17] which is found again in the uranyl nitrate.

The literature does not report sufficiently accurate data concerning the assignment of the absorption bands exhibited by the ligands, AB, ATB and 5-EB, the present study being limited only to the bands proper to the pyrimidine ring.[18,19]

The absorption bands assigned to the pyrimidine ring, 1402 cm^{-1}, 1467 cm^{-1} and 1570 cm^{-1} due to the in-plane vibrations and the absorption bands within the 724–680 cm^{-1} range ascribed to the out-of-plane vibrations, are found again in the compounds with the uranyl ion, with more or less obvious changes in their frequencies and intensity.

As can be seen, in the compound (I), the absorption maxima at 690 cm^{-1}, 1480 cm^{-1} and 1600 cm^{-1}, in (II) the absorption maxima at 730 cm^{-1}, 1390 cm^{-1}, 1450 cm^{-1} and 1600–1640 cm^{-1} and in (III) the absorption maxima, at 730 cm^{-1}, 1380 cm^{-1}, 1485 cm^{-1}, 1640 cm^{-1} and 1680 cm^{-1}, characterized the pyrimidine ring.

The absorption maxima of the uranyl ion (at 930 and 960 cm^{-1}) reappear in the mentioned compounds, namely in (I) at 950 cm^{-1}, in (II) at 912 and 950 cm^{-1} and in (III) at 912 cm^{-1}.

It must be mentioned that in (II), the appearing band, at 1540 cm^{-1} is ascribed[20] to the $-\mathrm{S}-\mathrm{C}\langle$ group also present in the ATB.

CONCLUSIONS

As results from the chemical and physical investigations performed in the present note, the three compounds herein studied contain ligands reacting more probable in the enolic form, the pyrimidine structure being consistent with the spectral behaviour of the compounds in i.r., as well as in u.v., and visible range.

Acknowledgement. The authors express their gratitude to Dr. D. Todor for the thermal measurements, to R. Giuşcă, for the registration of the diffractograms and to M. Elian for the registration of the i.r. spectra. The authors are indebted to Dr. C. Lepădatu, D. Cismaru and to D. Ciomîrtan for their assistance in the interpretation of the data.

ISOTOPIC EXCHANGE OF ACTIVE METHYL HYDROGENS. VII.[1]

KINETIC STUDY OF 2,4,6-TRIMETHYLPYRYLIUM SALTS IN DEUTERIUM OXIDE

Received September 30, 1972

The NMR spectra at various temperatures and pH values, of buffered deuterium oxide solutions of 2,4,6-trimethylpyrylium chloride or trifluoromethanesulphonate show a rapid decrease of the 4-methyl proton peak and a slower decrease of the peak due to the 2- and 6-methyl protons. Rate constants, activation energies and the pH dependence indicate a mechanism of the exchange *via* methylenepyrans (anhydrobases). Non-buffered solutions yield kinetic data indicating a pH lower than 1.

INTRODUCTION

2,4,6-Trimethylpyrylium salts (I) exchange fairly rapidly their nine methyl hydrogens in deuterium oxide, and very slowly their two β-standing hydrogens. Infrared spectra[2] or isotopic analyses[3] do not distinguish α- from γ-methyl groups; however, nuclear magnetic resonance spectra[4] give rise to distinct peaks for the α-methyl groups (τ 7.10 in SO_2) and the γ-methyl group (τ 7.26 in SO_2); previous observations indicated that the γ-methyl hydrogens exchange more rapidly than α-methyl hydrogens, both in 2,4,6-trimethylpyrylium perchlorate which contains the two kinds of methyl groups in the same molecule,[5] and in 2,4-diphenyl-6-methylpyrylium as compared with 2,6-diphenyl-4-methylpyrylium salts.[6]

A kinetic study of the deuteration of I in non-buffered and buffered medium is now described.

EXPERIMENTAL PART

2,4,6-Trimethylpyrylium chloride.[7] 2,4,6,-Trimethylpyrylium perchlorate[8] was introduced into a cold stirred mixture of 5% aqueous sodium hydrogen carbonate and benzene. The benzene layer was rapidly dried over sodium sulphate, then dry hydrogen chloride was bubbled into this benzene solution of 2,4,6-trimethylpyrylium pseudobase (4-methyl-3-hepten-2,6-dione) in the cold. A dark oily lower layer of 2,4,6-trimethylpyrylium chloride separated. The benzene layer was discarded and the very hygroscopic chloride was freed from benzene by keeping in an evacuated desiccator over phosphorus pentoxide and potassium hydroxide until a thick crystalline suspension resulted (a white pure product may be obtained by spreading this suspension on a porous plate in a dry box). If the evacuation is continued until all benzene leaves, the product is yellowish. The product can be stored for a few days in an evacuated desiccator. On longer storing it darkens. Alternatively, the pseudobase can be extracted by benzene from a mixture of aqueous trimethylpyrylium chloroferrate and sodium acetate.

2,4,6-Trimethylpyrylium trifluoromethanesulphonate (*triflate*) was prepared from acetic anhydride, *t*-butanol and trifluoromethanesulphonic acid.[9]

The properties of 2,4,6-trimethylpyrylium salts presented in Table 1 make it clear that the perchlorate cannot be employed in kinetic studies owing to its low solubility and that the triflate is the most advantageous.

Table 1

Properties of 2,4,6-trimethylpyrylium salts

Property	Perchlorate	Chloride	Triflate
Non-explosive	No	Yes	Yes
Water-soluble	Slightly	Yes	Yes
Non-hygroscopic	Yes	No	Yes
Conservable	Yes	No	Yes

NMR Spectra. The isotopic exchange was performed in NMR vials which were filled with a freshly prepared solution of 2,4,6-trimethylpyrylium salt in deuterium oxide or in a buffered ($NaOD + D_3PO_4$) deuterium oxide solution of different pH values (35—100 mg salt in 0.5 ml D_2O, i.e. 30—100 moles D_2O per mole I). The spectra were determined with a Varian A 60-A spectrometer at various intervals and at different temperatures, recording the aromatic and methyl proton peaks as well as the respective integral curves. The aromatic proton peak serves as an internal standard since its area is practically constant (the relative exchange rate for the aromatic protons being much smaller than the rates for methyl protons).[5] Heights *h* of integral curves for the methyl peaks were measured; where necessary, slight corrections were made by comparison with the aromatic proton peak which was assumed to be constant; ratios $h_\gamma/h_{0\gamma}$ and $h_\alpha/h_{0\alpha}$ were plotted semi-logarithmically against the time. By the method of least squares, straight lines were determined which fit the experimental points, yielding k_γ and k_α values (table 2). Since the initial $h_{0\alpha}/h_{0\gamma}$ ratio must be 2, and starts to increase because h_γ decreases more rapidly than h_α, this gives an internal check for the real zero time of the experiment, which must agree within fractions of a minute with the measured zero time.

[a] No buffer added.

The experimental points h/h_0 also yield in the semilogarithmic plot *versus* time half-lives $T_{1/2,\gamma}$ and $T_{1/2,\alpha}$ for the times when $\log(h/h_0) = 1.7$. These half-lives determined by visual interpolation may be used to compute $k_{\alpha,\mathrm{calc}}$ and $k_{\gamma,\mathrm{calc}}$ which are less accurate than those determined by the method of least squares but are comparable with them (table 2).

Though the pH of the solution does not change during the exchange and the isotopic composition of the solvent remains practically constant owing to the large excess of D_2O, some plots show slight departure from linearity, especially in the initial and final regions;

the former is probably due to the processes of dissolution and reaching the prescribed temperature which are not instantaneous; when the exchange has resulted in extensive deuteration, the integration of small NMR peaks becomes affected by larger errors because of the unfavourable signal-to-noise ratio.

DISCUSSION OF THE RESULTS

Experimental results are presented in table 2 which gives k_α and k_γ in function of temperature and pH value of the buffer solution for 2,4,6-trimethylpyrylium chloride and trifluoromethanesulphonate. The more reliable value, determined through the method of least squares, is listed first; k_{calc} is determined from $T_{1/2}$ by a less precise method.

From the data it is apparent that in the range of temperatures 40—100°, the ratio of deuterium exchange rates for the γ- and α-methyl group in I varies between ca. 8 and 20, in agreement with the average ratio of about 10 reported earlier, [5] and shows the tendency to decrease with increasing temperature. Therefore, to achieve a selective deuteration of the γ-methyl group (which can be useful in synthetic work for obtaining various labelled compounds from pyrylium salts [10,11]) it is advisable to have lower exchange temperatures, and therefore slower reactions.

A plot of log*k* *versus* pH reveals that at a given temperature the rate of exchange increases with the pH of the solution.

Experiments in non-buffered medium (table 2) show that the rate of exchange of the non-buffered solutions of trifluoromethane-sulphonate or chloride is very low, and corresponds in fact to an extrapolated pH of about 0.5.

The variation of the rate with temperature is reflected in the activation enthalpies (table 3) determined from the data in table 2 by a least-squares linearization. Very slow (α-methyl exchange at pH 2.07) or very fast reactions (γ-methyl exchange at pH 3.70) are affected by larger errors and have therefore been omitted from table 3. The trend evident from table 3 is that the higher are the pH values the lower is the activation barrier and that α-methyl groups have an activation energy higher than γ-methyl with 2.5—4 k cal/mole.

The above kinetic data are compatible with a mechanism involving the transfer of a proton from a methyl group of I to a base, followed by a rapid reaction of the resulting methylenepyran with a deuteron originating from the solvent. A molecular orbital calculation of the α- *versus* γ-methylenepyran [12,13] reveals the higher delocalization in the latter, more symmetrical pyran, which is formed more rapidly than the former, despite the lower π-electron density of α- than of γ-positions, evidenced

both by NMR experiments[4] and by theoretical calculations.[14] However, with less electronegative heteroatoms the situation is reversed, as pointed out by Tupitsyn and Zatsepina for pyridinium salts, where α-methyl groups exchange faster than γ-methyl groups.[15,16]

PHENYL BENZYL SULPHIDES

M. IOVU and ANCA ANGELESCU

University of Bucharest, Physics Departments

Chair of Chemistry, Şos. Panduri 90, Bucharest, Romania

Received May 18, 1972

The method previously described by us, in the synthesis of polyethers and aromatic bis-ethers was applied also to the synthesis of phenyl benzyl sulphides. For the synthesis of phenylbenzyl sulphides, the thiophenol or the *p*-methylthiophenol were converted into alkali thiophenolates by treating with sodium hydroxide. After the removal of the water (resulted from the reaction) by azeotropic distillation with ethanol and benzene mixture, the thiophenolates were treated with the chloromethylated derivative. The corresponding sulphides resulted.

Discovering an easy method for the synthesis of aromatic polyethers [1] and bis-ethers, [2,3] we passed to the synthesis of aromatic sulphides and we used the same method.

For the first time, in the synthesis of phenyl benzyl sulphide the reaction between sodium thiophenolate and benzyl chloride has been used.[4] But, to obtain the anhydrous sodium thiophenolate, prior to our investigations, the authors[4] have synthesized the sodium methoxide, of sodium and methanol, followed by the reaction between methoxide and thiophenol.

According to Brintzinger, Schmahl and Witte [5] the phenyl benzyl sulphide was obtained together with another reaction product, from chloromethylsulphochloride ($ClCH_2SCl$) and benzene, in carbon disulphide in the presence of aluminium chloride as catalyst.

More recently [6] the reaction between phenol and benzyl mercaptans in the presence of the hydrochloric acid in a closed tube has been used for the synthesis of phenyl benzyl sulphide. The authors of this method obtained a liquid product. The authors [4,5] of the above method obtained solid products with m.p. 40–41° and respectively m.p. 44°.

[6] S. Oae and R. Kiritani, *Bull. Chem. Soc. Japan*, **38**, 1381 (1965).

Among the substituted phenyl benzyl sulphides, only *p*-tolyl benzyl sulphide was synthesized from *p*-methyl thiophenol and benzyl chloride. *p*-Tolyl benzyl sulphide has m.p. 44°. [7]

In some other papers we have shown the possibility to obtain polyethers [1] and aromatic bis-ethers [2,3] by using the condensation of aromatic chloromethylated derivatives with alkali phenoxides in non-aqueous medium, without the aid of a catalyst.

According to our method, the alkali phenoxides have been obtained from phenols and alkali hydroxides (and not from alkali alkoxide or alkali metal and phenol) in a mixture of solvents (ethanol and benzene) in which the phenol is soluble. The resulting water is removed by azeotropic distillation (as a mixture of ethanol-benzene-water). The anhydrous alkali phenolate is treated, in the same mixture of solvents (ethanol-benzene), with the halogenated derivative.

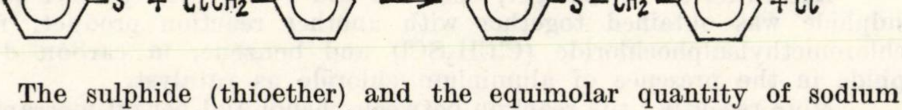
The condensation takes place at 70–75° with formation of alkali chloride and the corresponding ethers, which precipitated. These are easily separated from the solvents, by filtering and the sodium chloride is removed by water washing.

The method used for polyethers and aromatic bis-ethers synthesis is applied with good results for phenyl benzyl sulphides synthesis too, without essential changes.

Thus, to obtain sodium thiophenolate we have used thiophenol, sodium hydroxide and a mixture of benzene and ethanol, too, as a reaction medium, which permits the removal of the water, resulting from the reaction, as an azeotropic ethanol-water-benzene mixture :

$$ArSH + NaOH \rightarrow ArSNa + H_2O$$

When introducing the chloromethyl derivative, the nucleophilic attack of the thiophenolate ion on the halogenated derivative takes place, for instance :



The sulphide (thioether) and the equimolar quantity of sodium chloride result, and they precipitate.

The sulphides with a higher melting point precipitate together with the sodium chloride and can be separated by filtering from the solvents and from the unreacted dissolved raw materials.

The sodium chloride is removed by water washing on the filter. The sulphide is recrystallized from ethanol.

The sulphides with a lower melting point do not crystallize in the reaction mixture at the same time with sodium chloride ; to separate them, they are washed with water in a separatory funnel when the sodium chloride and a part of the unreacted raw materials are removed. Then, some of the sulphides crystallize in the solution separated in the separatory funnel, after cooling and then, their recrystallization from ethanol follows. Other sulphides are not crystallized and they are purified by distillation in vacuum.

---

[7] E. FROMM, *Liebigs Ann. Chem.*, **396**, 75 (1931).

In this paper we present 8 sulphides, 6 of them being unknown. All the 8 sulphides are synthesized from thiophenol or *p*-methylthiophenol and benzyl chloride, 1-chloromethyl-4-methyl-benzene, 1-chloromethyl-2,4-dimethylbenzene or 1-chloromethyl-2,5-dimethylbenzene, using the new method.

RESULTS AND DISCUSSIONS

Table 1 gives the structural formulas of the synthesized sulphides, their melting points (or their boiling points) the microanalytical results of sulphur determination, λ_{max} and ε_{max} from UV spectrography and their yields.

By studying the data we notice that the melting points increase at the substitution of a methyl radical on the aromatic nuclei not directly connected with the sulphur atom and they are to a little extent influenced by the substitution of the methyl radical on the aromatic nuclei directly connected with the sulphur atom. The melting points decrease at the sulphides in which the aromatic nuclei not directly connected with the sulphur atom are substituted for two methyl radicals. If none of the methyl radicals is in the *para* position, the sulphides are liquid.

The synthesized sulphides, characterized by a direct connection with the sulphur function (thioether) of a benzenic nucleus and of a second one through an intermediary methylene group, $Ar-S-CH_2-Ar$, can be considered as mixt ones.

This fact is also shown by the wavelength value of the maximum of UV absorption. For these sulphides, the wavelength value is to be found between 255 and 259 nm (table 1), while for the aliphatic sulphides [8] the wavelength is to be found at about 210 nm and for the diphenyl sulphides [8] at about 280 nm.

The sulphides synthesized by us hardly absorb in the 200—210 nm area, characteristic of the aliphatic sulphides.

The wavelength values corresponding to the UV absorption maxima of an intensive band (table 1) demonstrate the presence of a less intensive bathochrom effect in the substitution of the benzenic nuclei, which are connected with a methyl radical in the *para* position.

In the IR spectra of the sulphides synthesized by us, the absorption band for the C—S bond could not be singled out; this is weak and is to be found in the 600—700 cm^{-1} area, where the absorption takes place also due to the out-of-plane vibrations of the aromatic nucleus.

	$C_{15}H_{16}S$	14.05 13.97	44.5–45.5	256	0.445	51
	$C_{16}H_{18}S$	13.50 13.24	47–48	259	0.272	17
	$C_{15}H_{16}S$	14.05 14.09	173–174 (/3 mm)	256	0.268	51
	$C_{16}H_{18}S$	13.50 13.32	166–167 (/2 mm)	258	0.364	50

We have obtained phenyl benzyl sulphide with the highest yield. The yields diminished with the increase of the number of methyl radicals substituted on the aromatic nuclei.

In this case, the yields are very small because the sulphides do not crystallize in the reaction mixture. On washing the reaction mixture in the separatory funnel and then during distillation many losses are recorded.

EXPERIMENTAL

Thiophenol and 4-methyl thiophenol were obtained by reducing benzenesulphochloride and toluenesulphochloride with zinc and sulphuric acid (33%).[9]

Benzyl chloride was a "Riedel" commercial product.

1-Chloromethyl-*p*-toluene was synthesized by photochemical chlorination of *p*-xylene with sulphuryl chloride, using benzoyl peroxide as activator.

1-Chloromethyl-2,4-dimethylbenzene and 1-chloromethyl-2,5-dimethylbenzene were synthesized by chloromethylation of *m*-xylene and *p*-xylene, using paraformaldehyde, hydrochloric acid and phosphoric acid.

The determination of the sulphur was made by the oxidation of sulphides with oxygen in the presence of platinum catalyst, and with hidrogen peroxide, followed by volumetric determination of sulphuric acid.[10]

The UV spectra were obtained with the Specord, Zeiss-Yena, spectrophotometer, and the IR spectra with the UR-20, Zeiss-Yena, apparatus.

SYNTHESIS OF PHENYL BENZYL SULPHIDE

In a double-necked, 50 ml flask, ground joint, equipped with an ascending refrigerator and a thermometer, we have inserted 2.754 g thiophenol (1/40 mol), 1.010 g NaOH (1/40 mol plus an excess of 1/4000 mol) and 30 ml of ethanol-benzene mixture (in the ratio 1 : 1 in volume). The mixture is heated to the boiling point for 3 hours, till the sodium thiophenolate forms. The reflux refrigerator is then changed to a distillation refrigerator and 15 ml azeotropic mixtures are distilled to remove the water resulting from the reaction. After cooling of the flask, 3.139 g benzyl chloride (1/40 mol) are added, the distillation refrigerator is again changed for the refluxing one, to which a tube with calcium chloride is connected and is heated for 3 hours at 65—67°. Sodium chloride first forms, which precipitates and then sulphide which becomes abundent after cooling of the reaction flask to 5°.

The reaction mixture is filtered, when the solid sodium chloride and the solid sulphide separate from the solvent and the liquid unreacted raw materials. The solid mixture is now water washed to remove sodium chloride. The precipitate is dried in vacuum; 4.012 g phenyl benzyl sulphide results and after two recrystallizations its melting point will be 39.5°.

The 4-methyl-phenyl benzyl sulphide, phenyl 4-methyl benzyl sulphide and 4-methylphenyl 4-methyl-benzyl sulphide were obtained in a similar way.

Phenyl 2,4-dimethyl-benzyl sulphide and 4-methyl-phenyl 2,4-dimethyl-benzyl sulphide did not crystallize from the reaction mixture, and that is why it was washed with water in the separatory funnel to remove the sodium chloride and a part of the unreacted thiophenol.

The product of the synthesis of phenyl 2,4-dimethyl-benzyl sulphide was distilled in vacuum, after drying on calcium chloride.

From the fraction distilled at 148—150°/2 mm, after cooling, phenyl 2,4-dimethylbenzyl sulphide crystallized; after the recrystallization from anhydrous ethanol, the melting point is 45.5—46.5°.

---

[9] Weygand–Hilgetag, "Organisch-Chemische Experimentierkunst" 3. Auflage, Johann Ambrosius Barth–Verlag, Leipzig, 1964, S. 711.

[10] T. N. Kasterina, L. S. Kalinina, "Analiza chimică a rășinilor sintetice și a materialelor plastice" — traducere din limba rusă, Ed. Tehnică, București, 1965, p. 42.

4-Methyl-phenyl 2,4-dimethyl-benzyl sulphide crystallized from the dry washed product, without any distillation, at a reduced pressure.

Phenyl 2,5-dimethyl-benzyl sulphide and 4-methyl-phenyl 2,5-dimethyl-benzyl sulphide have been identically processed, but they still remained liquid after distillation in vacuum.

Phenyl 2,5-dimethyl-benzyl sulphide has b.p. 173—174°/3 mm, with $\rho_{20} = 1.0742$ and $n_D^{20} = 1.6120$; $MR_{calc} = 72.186$, $MR_{found} = 73.715$.

4-Methylphenyl 2,5-dimethylbenzyl sulphide has b.p. 166—167°/2 mm with $\rho_{20} = 1.0501$ and $n_D^{20} = 1.6011$; $MR_{calc} = 77.228$, $MR_{found} = 77.801$.

CONCLUSIONS

The method described in our first paper, for the aromatic bis-ethers synthesis, may be used with good results for aromatic sulphides synthesis too.

Anhydrous, alkali thiophenolates can be obtained by treating phenyl-mercaptans with sodium hydroxide and the removal of water derived from the reaction, by azeotropic distillation.

Anhydrous alkali thiophenolates react easily with dichloromethylated derivatives in ethanol-benzene mixture.

Phenyl benzyl sulphide and tolyl benzyl sulphide have their melting points identical with the products synthesized in other ways. Other sulphides synthesized by us are not yet described.

DER EINFLUSS DER KETTENLÄNGE EINIGER *n*-ALKANE AUF IHRE PEROXYDIERUNGSGESCHWINDIGKEIT MIT MOLEKULAREM SAUERSTOFF, IN FLÜSSIGER PHASE

I. DRIMUŞ und I. T. IONESCU

Aus dem Laboratorium für Organisch-Chemische Technologie
Technische Hochschule, Bukarest, Calea Victoriei 149

Eingegangen am 24. Juni 1972

In flüssiger Phase wurden *n*-Dekan, *n*-Dodekan, *n*-Tetradekan, *n*-Oktadekan, *n*-Eikosan, *n*-Tetrakosan und *n*-Pentatriakontan mit molekularem Sauerstoff oxydiert. Mit Peroxyde als Initiatorem, wächst die Ansammlung von peroxydischem Sauerstoff in der Reaktionsmasse, bei kleinen Umsätzen, mit der Temperatur, Reaktionsdauer und Kettenlänge. Es wurde eine Gleichung zwischen der Zahl der Kohlenstoffatome der *n*-Alkanmolekülen und der Reaktionsgeschwindigkeit festgestellt.

Das Verhältnis zwischen der Oxydierungsgeschwindigkeit der *n*-Alkane und deren Kettenlänge wurde bisher nur wenig studiert.

Einige Verfasser haben in Gasphase, andere, in flüssiger Phase gearbeitet. Es wurden verschiedene Katalysatoren angewendet und die Oxydierung bis zu Alkoholen und Ketonen, von einigen Verfassern, von anderen wieder, bis zu Carbonsäuren geleitet.

Cullis [1] schreibt den Einfluß der Methylgruppen aus den Molekülen der *n*-Alkane zu, daß deren Oxydierungsgeschwindigkeit folgende Werte hat; CH_3-CH_3 ... 0,0011 ; $CH_3-CH_2-CH_3$ ... 0,1 ; $CH_3-(CH_2)_2-CH_3$ ... 0,5 ; $CH_3-(CH_2)_3-CH_3$ ... 7,5 ; $CH_3-(CH_2)-CH_3$ ... 200 und $CH_3-(CH_2)_8-CH_3$ ... 1380.

Zilberg und Smirnova oxydierten mit molekularem Sauerstoff n-$C_{12}H_{26}$, n-$C_{13}H_{28}$, n-$C_{14}H_{30}$ und n-$C_{15}H_{32}$, in flüssiger Phase, mit Cobaltstearat als Katalysator; sie bemerkten, daß die Reaktionsgeschwindigkeit gleichmäßig mit der Zahl der Methylengruppen in den Molekülen ansteigt.[2]

Tiscovski land, daß bei der Oxydierung der Alkane, in flüssiger Phase, mit molekularem Sauerstoff, in Gegenwart von Mangannaphthenat, die Reaktionsgeschwindigkeit der Säurenbildung mit der Länge der Kohlenwasserstoffkette wächst.[3]

---

[3] V. K. Tiscovski, *Zhur. priklad. Khim.*, **30**, 493 (1957).

In der vorliegenden Arbeit wurde die Oxydierung von *n*-Alkanen mit $C_{10}...C_{35}$ durch Einblasen von Sauerstoff, in flüssiger Phase, ohne Katalysatoren, ausgeführt. Die Induktionsperiode wurde ausgelassen, da man Spuren von Peroxyd verwendet hat. Der Oxydierungsverlauf wurde durch Bestimmung des peroxydischen Sauerstoffs in der Reaktionsmasse verfolgt.

Es sei bemerkt, daß die Reaktion sehr empfindlich ist, und daß die angesammelte Peroxydmenge nicht nur von der Natur des *n*-Alkans, von Temperatur und Oxydierungsdauer, sondern sehr stark, auch von Menge und Verteilugungsgrad des Sauerstoffes, wie auch von Form, Größe und Baumaterial des Reaktors abhängt.

DAS AUSLASSEN DER INDUKTIONSPERIODE

Führt man fein verteilten Sauerstoff durch einen flüssigen *n*-Alkan, bei geeigneter Temperatur, so beginnt die Reaktion nach einer mehr oder weniger kurzen Induktionsperiode, durch Ansammlung von Peroxyden in der flüssigen Masse. Durch viele gleichzeitige, aufeinanderfolgende und angeleitete Reaktionen treten mit der Zeit in der Reaktionsmasse verschiedene mono-, di-, und polisubstituierte Verbindungen, so wie auch Abbauprodukte in immer größerer Zahl und Menge auf.

Wir haben uns mit der Ansammlungsperiode der Peroxyde in Abhängigkeit von Zeit befaßt. Um vergleichbare Ergebnisse zu erzielen, mußte man die Induktionsperiode auslassen.

Um die Reaktion einzuleiten, bzw. die Induktionsperiode auszulassen, schlugen Geisler, Asinger und Wien vor, dem in den Reaktor eingeführten Sauerstoff, Ozon beizumischen; zu demselben Zweck gebrauchte Emanuel Stickstoffdioxyd. [4,5]

Wir konnten keine löslichen Salze von Schwermetallen (Co, Mn, Cr, usw.) verwenden, da diese Katalysatoren, obwohl sie die Induktionsperiode beseitigen, die Peroxyde mit großer Geschwindigkeit zerlegen und so die *n*-Alkane zu Verbindungen mit höherem Oxydierungsgrad (hauptsächlich Carbonsäuren) oxydieren.

In unserem Fall konnte die Induktionsperiode ausgelassen werden, entweder durch eine Vorbehandlung der Reaktionsmasse mit 0,1 $mg.g^{-1}$ eines geeigneten Peroxyds, [6] oder durch die Ausführung der Oxydierung in einem Feld ionisierender Strahlungen sowie auch durch Vorbestrahlen der zu oxydierenden *n*-Alkane mit uv-Strahlungen, γ- [7,8] Strahlungen oder Ultraschall. [9]

Nach dem Start, hat man die Ansammlung der Peroxyde, bei der Oxydierung eines n-Alkans, bei vergleichbaren Bedingungen, in Abhängigkeit von Zeit und Temperatur, studieren können.

Abb. 1 stellt die bei der Oxydierung des n-Dodekans mit molekularem Sauerstoff erhaltenen Ergebnisse dar. Man bemerkt, daß in den ersten 6 Stunden, bei niedrigeren Temperaturen, die Sauerstoffansammlung, linear verläuft; nur bei höheren Temperaturen erscheint ein Maximum.

Gleichartige Kurvenfamilien geben auch die in der gegenwärtigen Arbeit studierten höheren und niedrigeren Homologe des n-Dodekans.

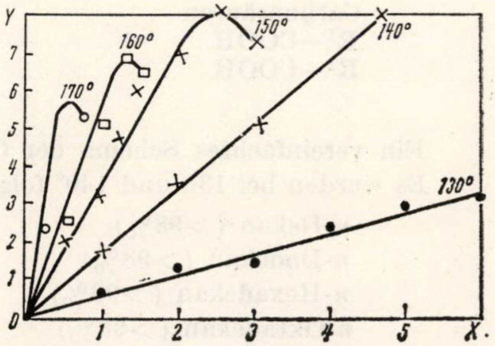

Abb. 1. — Die Oxydierung des n-Dodekans. Die Ansammlung von peroxydischem Sauerstoff in Abhängigkeit von Zeit und Temperatur (Reaktor von 150 cm^3).

X = Oxydierungsdauer (Stunden); Y = Peroxydzahl (mg O/g).

Um vergleichbare Ergebnisse zu erhalten, wurden verschiedene n-Alkane je 3 Stunden, bei 130 und 140° oxydiert, in Bedingungen, in welchen die von uns studierten n-Alkane lineare Ansammlungen von peroxydischem Sauerstoff in der Reaktionsmasse weisen.

Der Mechanismus der Alkanoxydierung ist nicht vollständig geklärt. Wahrscheinlich bilden Alkylhydroperoxyde die erste Stufe der Oxydierung. Nachher, bei größeren Umsätzen, treten in der Reaktionsmasse, unter anderen Ketone, Carbonsäuren usw. auf. Diese Produkte peroxydieren sich wiederum.

Bei kleinen Umsätzen (am Anfang der Oxydierung und bei mäßigen Temperaturen) kann man annehmen, daß die (jodometrisch bestimmte) Peroxydzahl der Reaktionsmasse den Alkylhydroperoxyden entspricht aber mit wachsendem Umsatz, haben die Peroxyde (Hydroperoxyde) der Zwischenprodukte ein größeres Gewicht.

In der Reaktionsmasse gelöste oder dispergierte Salze von Schwermetallen (Fe, Co, Ni Mn, Cr, usw.) wiedersetzen sich, wie gezeigt, der Peroxydansammlung.[8] So, zum Beispiel, in Gegenwart von 0,1% Cobaltnaphthenat, treten Peroxyde nur als Spuren auf, obwohl der Oxydierungsprozeß zur Bildung von Alkoholen, Ketonen, Carbonsäuren usw. mit größerer Geschwindigkeit stattfindet.

In unseren Arbeiten haben wir nur sehr reine Kohlenwasserstoffe verwendet und die Verunreinigungen mit Salzen von Schwermetallen, die die Peroxydansammlung unvorteilhaft beeinflussen könnten, gemieden.

$R^1 - COOH$
$R^2 - COOH$
Hydroperoxyde von
Carbonsäuren
usw.

Ein vereinfachtes Schema der Oxydierung von *n*-Alkane.

Es wurden bei 130 und 140° folgende Kohlenwasserstoffe oxydiert:

n-Dekan ($>98\%$)
n-Dodekan ($>98\%$)
n-Hexadekan ($>98\%$)
n-Oktadekan ($>98\%$)
n-Eikosan ($>95\%$)
n-Tetrakosan ($>95\%$)
n-Pentatriakontan.

Diese Stoffe waren alkenefrei; ihre Verunreinigungen waren nahe gelegene, höhere und niedrigere Homologe. Sie wurden aus natürlichen Fettsäuren synthesisiert.

Die Oxydierung wurde durch Einleitung von fein verteiltem Sauerstoff in das, vorher mit 100 ppm Alkylperoxyde behandeltem Kohlenwasserstoff, ausgeführt. Man arbeitete ohne metallische Katalysatoren.

Die Peroxadzahl wurde jodometrisch bestimmt.

Wie aus Abb. 2 hervorgeht, verläuft in den ersten 180 Minuten die Ansammlung des peroxydischen Sauerstoffes linear, im Einklang mit der Gleichung:

$$C = A . t . n .$$

wo: C = mg aktiver Sauerstoff pro Gramm oxydierte Substanz; t = Oxydierungszeit, in Minuten; n = Zahl der Kohlenstoffatome aus dem zu oxydierenden *n*-Alkanmolekül; A = eine spezifische Konstante für den verwendeten Apparat und die Arbeitstemperatur, ausgedrückt in mg aktivem Sauerstoff pro Gramm oxydierte Substanz und Minute.

Mit dem von uns verwendeten Apparat, war der mittlere Wert für A_{130° $7{,}65 . 10^{-4}$ mg 0/g.min, und für A_{140° $2{,}39 . 10^{-3}$ mg O/g.min.

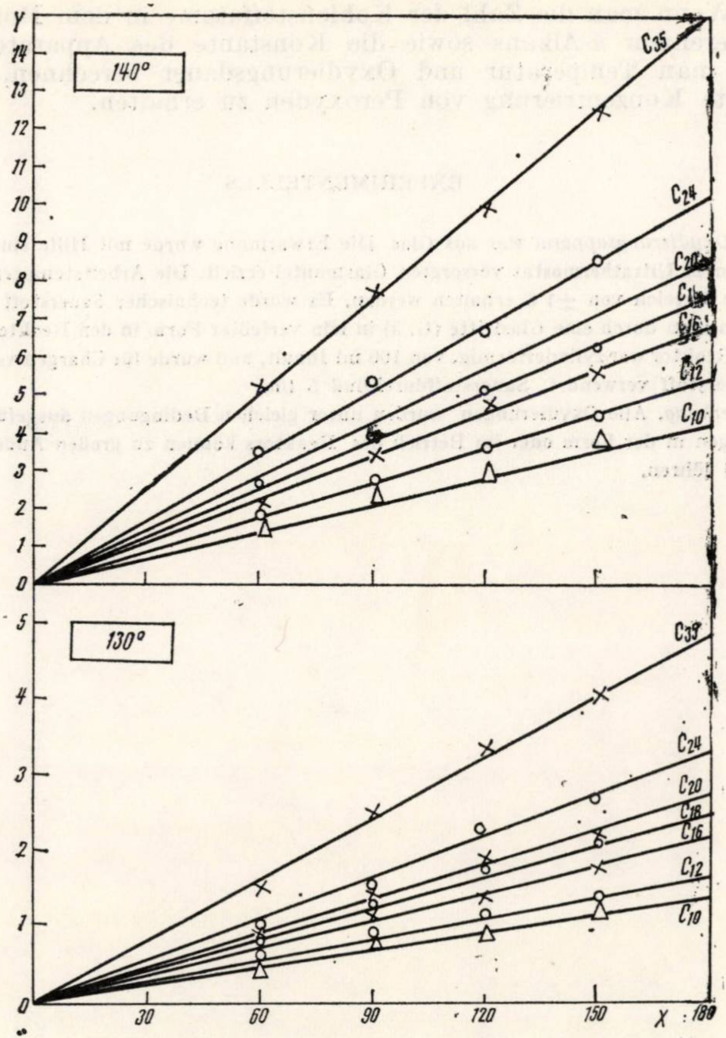

Abb. 2. — Ansammlung von aktivem Sauerstoff in der Reakionsmasse bei der Oxydierung einiger *n*-Alkane bei 130° und 140°.
X = Oxydierungsdauer (Minuten) ; Y = Peroxydzahl (mg O/g).

SCHLUSSFOLGERUNG

1. Die Peroxydierungsgeschwindigkeit der *n*-Alkane (C_{10}—C_{35}), bei Temperaturen von 130 und 140°, wächst gleichmäßig mit der Zahl der Kohlenstoffatome in dem Molekül.

2. Um vergleichbare Ergebnisse zu erzielen muß man die Anwesenheit metallilscher Katalysatoren vermeiden und die Reaktionsmasse vorher mit organischen Peroxyden behandeln („Besamung").

3. Wenn man die Zahl der Kohlenstoffatome in dem Molekül des zu oxydierenden *n*-Alkans sowie die Konstante des Apparates kennt, so kann man Temperatur und Oxydierungsdauer berechnen, um die erwünschte Konzentrierung von Peroxyden zu erhalten.

EXPERIMENTELLES

Der Oxydierungsapparat war aus Glas. Die Erwärmung wurde mit Hilfe eines mit Glyzerin aus einem Ultrathermostat versorgten Glasmantel erzielt. Die Arbeitstemperatur konnte konstant im Bereich von ±1°C erhalten werden. Es wurde technischer Sauerstoff (99 %) verwendet, den man durch eine Glasfritte (G. 3) in fein verteilter Form in den Reaktor einführte.

Der Reaktor war zylinderförmig, von 100 ml Inhalt, und wurde für Chargen von je 100 ml Kohlenwasserstoff verwendet. Sauerstoffdurchfluß 5 l/h.

Anmerkung. Alle Oxydierungen wurden unter gleichen Bedingungen ausgeführt. Kleine Veränderungen in der Form oder im Betrieb des Reaktors können zu großen Änderungen der Peroxydzahl führen.

NEUE ORGANISCHE PIGMENTE–ISATINDERIVATE. III

STUDIUM DER IR-SPEKTREN EINIGER 2-ARYLAMINOINDOXYLE UND 3-ARYLIMINOOXINDOLE

R. BACALOGLU und B. D. BADER

Vom Lehrstuhl für organische Chemie der Fakultät für industrielle Chemie,
Timişoara, Str. Bocşa 6 und vom Forschungslaboratorium der industriellen Gruppe
für Petrochemie, Piteşti, Şos. Giurgiului 127

Eingegangen am 19. Mai 1972

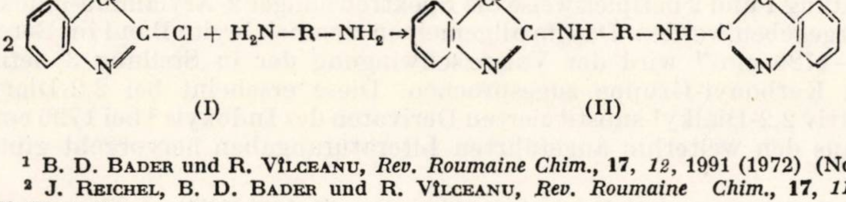
Es wurden die Spektren der im Titel genannten Verbindungen im Bereich 400 bis 4000 cm^{-1} untersucht. Durch Auslegen der dem heterozyklischen System charakteristischen Bande wurden die Strukturen der untersuchten Verbindungen festgelegt und Überlegungen über die Art ihrer Assozierung in der Kristallstruktur unternommen.

Im Rahmen der bisherigen Forschungen wurde eine Reihe von Pigmenten, Derivate des Aminoindoxyls, [2] sowie eine andere Reihe Derivate des Iminooxindols [1,2] synthetisiert, welche reelle Anwendungsmöglichkeiten zum Einfärben von Polyolefinen und Polyvinylchlorid bieten. Zur besseren Kenntnis der Eigenschaften dieser Verbindungen sowie zur Bestimmung ihrer Struktur haben wir ein Studium durch IR-Spektroskopie vorgenommen.

ERGEBNISSE UND DISKUSSION

a) 2-ARYLAMINO-INDOXYLE

Die untersuchten 2-Arylamino-indoxyle wurden durch die Reaktion des 2-Chlorindolenin-3-ons (Isatin-2-chlorid) mit verschiedenen Diaminen in *o*-Dichlorbenzol bei Erwärmen unter Rückfluß erhalten.



(I) (II)

---

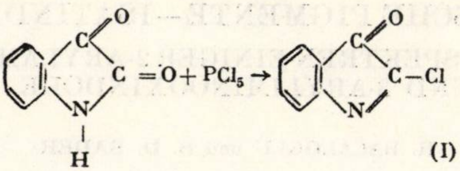
[2] J. Reichel, B. D. Bader und R. Vîlceanu, *Rev. Roumaine Chim.*, **17**, *11*, 1889 (1972) (Note I).

Das Isatin-2-chlorid wurde seinerseits nach älteren Literaturangaben durch Chlorierung des Isatins mit PCl_5 in Chlorbenzol hergestellt.



(I)

Die Struktur der letzten Verbindung wurde bis heute noch nicht vollkommen durch physiko-chemische Messungen bestätigt.

Tabelle 1

Die wichtigsten Banden des 2-Aminoindoxyl-Systems in Verbindungen der Struktur II

Symbol	Diamin entsprechend R aus Struktur II	Valenzschwingungen entsprechend (cm^{-1})				
		C=O	C=N	N−H	C−N	
					N-Indoxyl	N-Aryl
IV	1,4-Phenylendiamin	1715	1610	3400 2850	1310	1210
V	1,3-Phenylendiamin	1710	1605	3400 sehr breit	1320	1200
VI	2,4-Touilendiamin	1715	1610	3400 sehr breit	1320	1200
VII	Benzidin	1710	1610	3400 2850	1250	1190
VIII	*o*-Tolidin	1710	1605	3350 2850	1270	1190
IX	*o*-Dianisidin	1715	1610	3370 2850	1250	1200
X	1,5-Diaminoanthrachinon	1720	1600	3400 sehr breit	1260	1200
XI	1,4-Diaminoanthrachinon	1715	1610	3400 sehr breit	1270	1200

In Tabelle 1 werden die wichtigsten, den Schwingungen des 2-Aminoindoxyl-System entsprechenden Bänder zusammengefaßt, während in Abbildung 1 und 2 beispielsweise die Spektren einiger 2-Arylamino-indoxyle wiedergegeben werden. Das im allgemeinen ziemlich breite Band im Bereich 1710—1720 cm^{-1} wird der Valenzschwingung der in Stellung 3 befindlichen Karbonyl-Gruppe zugesprochen. Diese erscheint bei 2,2-Diaryl-, respektiv 2,2-Dialkyl-substituierten Derivaten des Indoxyls [3] bei 1720 cm^{-1}. Wie aus den weiterhin angeführten Literaturangaben hervorgeht gibt es anscheinend keine klaren Unterschiede zwischen der Lage der Bande, welche den Valenzschwingungen der Karbonylgruppen aus Stellung 2 und 3 entsprechen, weshalb für die Klärung dieses Strukturteiles die untersuchten Schwingungen keine besondere Anzeigen liefern.

---

[3] B. Wittkop und A. Ep, *J. Amer. Chem. Soc.*, **73**, 5664 (1951).

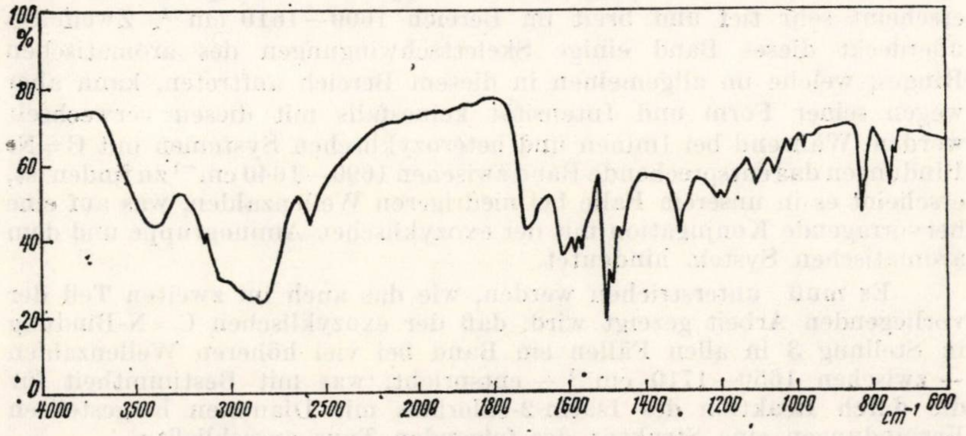


Abb. 1. — Das Infrarotspektrum des Bis-(Indolenin-3-on-2-yl)-phenylendiamins-1,4 in KBr-Preßling (600—4000 cm^{-1}).

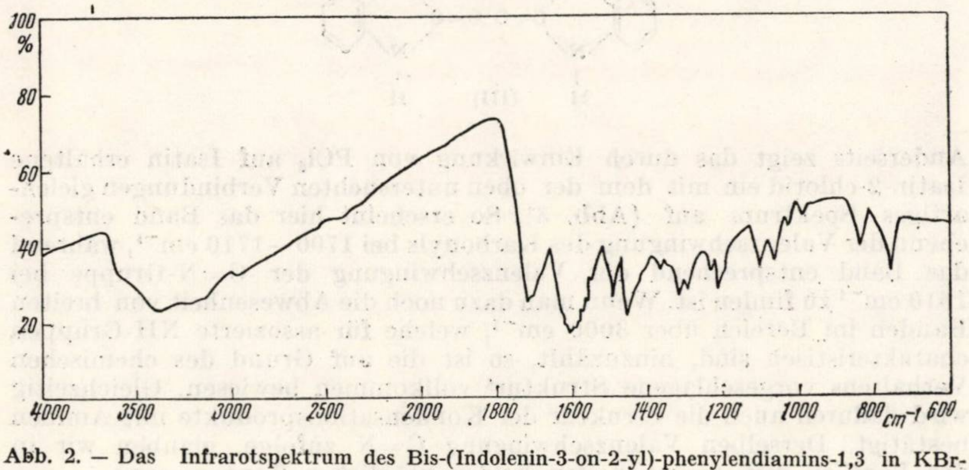

Abb. 2. — Das Infrarotspektrum des Bis-(Indolenin-3-on-2-yl)-phenylendiamins-1,3 in KBr-Preßling (600—4000 cm^{-1}).

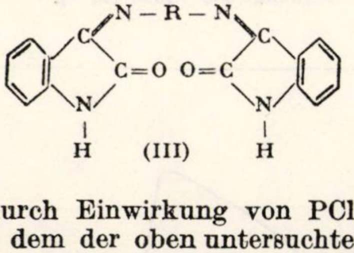
Da die untersuchten Verbindungen zweifellos Assozierungen durch Protonbindungen aufweisen, welche im allgemeinen die Lage des Bandes welches der Karbonylgruppe entspricht beeinflussen, wobei eine Verschiebung gegen kleinere Wellenzahlen mit ca. 10—20 cm^{-1} zu verzeichnen ist, und da Ketone mit Karbonylgruppen an 5-Atomringen allgemein dieses Band bei 1745 cm^{-1} aufweisen, wird es klar, daß dieses Band keinesfalls deutlich durch Konjugation der Ketongruppe mit den ungesättigten Gruppen des Systems wie – aromatischer Ring und Doppelbindungen $C=N$ – beeinflußt wird.

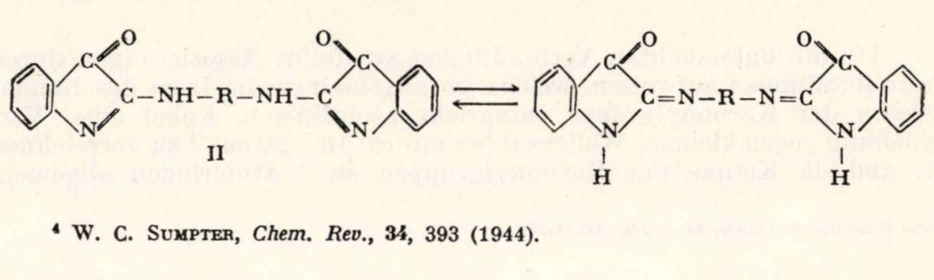
Das der Valenzschwingung der Gruppe $C=N$ entsprechende Band erscheint sehr tief und breit im Bereich 1600–1610 cm^{-1}. Zweifellos überdeckt dieses Band einige Skelettschwingungen des aromatischen Ringes, welche im allgemeinen in diesem Bereich auftreten, kann aber wegen seiner Form und Intensität keinesfalls mit diesen verwechselt werden. Während bei Iminen und heterozyklischen Systemen mit $C=N$ Bindungen das entsprechende Band zwischen 1690–1640 cm^{-1} zu finden ist, erscheint es in unserem Falle bei niedrigeren Wellenzahlen, was auf eine hervorragende Konjugation mit der exozyklischen Aminogruppe und dem aromatischen System hindeutet.

Es muß unterstrichen werden, wie das auch im zweiten Teil der vorliegenden Arbeit gezeigt wird, daß der exozyklischen $C=N$-Bindung in Stellung 3 in allen Fällen ein Band bei viel höheren Wellenzahlen – zwischen 1650–1710 cm^{-1} – entspricht, was mit Bestimmtheit für die durch Reaktion des Isatin-2-chlorides mit Diaminen hergestellten Verbindungen eine Struktur des folgenden Typs ausschließt:



(III)

Anderseits zeigt das durch Einwirkung von PCl_5 auf Isatin erhaltene Isatin-2-chlorid ein mit dem der oben untersuchten Verbindungen gleichartiges Spektrum auf (Abb. 3). So erscheint hier das Band entsprechend der Valenzschwingung des Karbonyls bei 1700–1710 cm^{-1}, während das Band entsprechend der Valenzschwingung der $C=N$-Gruppe bei 1610 cm^{-1} zu finden ist. Wenn man dazu noch die Abwesenheit von breiten Banden im Bereich über 3000 cm^{-1}, welche für assozierte NH-Gruppen charakteristisch sind, hinzuzählt, so ist die auf Grund des chemischen Verhaltens vorgeschlagene Struktur[4] vollkommen bewiesen. Gleichzeitig wird dadurch auch die Struktur der Kondensationsprodukte mit Aminen bestätigt. Derselben Valenzschwingung $C=N$ zufolge, glauben wir in der Lage zu sein zwischen den beiden möglichen Tautomeren:



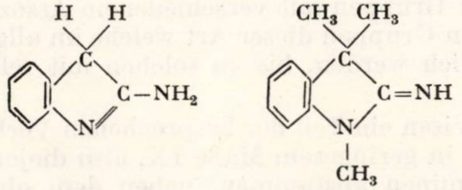
II

---

[4] W. C. Sumpter, *Chem. Rev.*, **34**, 393 (1944).

denjenigen mit endozyklischer C=N-Gruppe auf Grund der wie weiter oben schon genannten niedrigwelligen Stellung des Bandes, sowie der Analogie mit dem Spektrum des Isatin-2-chlorids als reell zu betrachten.

Es wurde auch in anderen ähnlichen Fällen schon bewiesen, daß für exozyklische C=N-Bindungen Banden bei höheren Frequenzen charakteristischer sind als für endozyklische, wie das auch aus dem folgenden Beispiel hervorgeht[5]:



$\nu_{C=N}$ 1642 cm^{-1} 1653 cm^{-1}

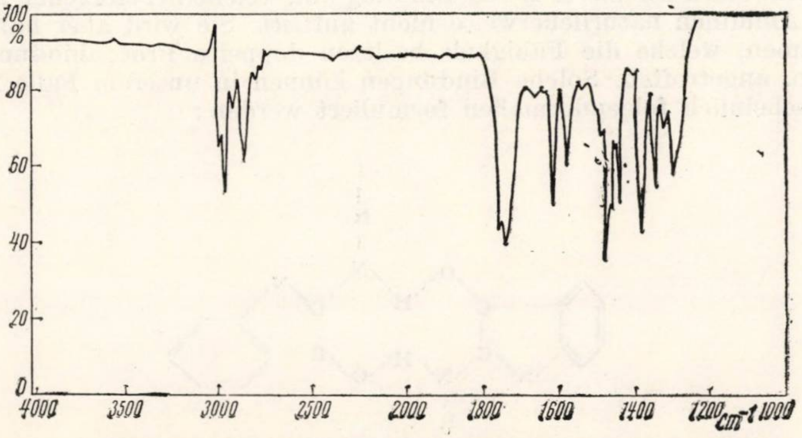


Abb. 3. — Das Infrarotspektrum des Isatin-2-chlorids in Chloroform-Lösung (1000—4000 cm^{-1}).

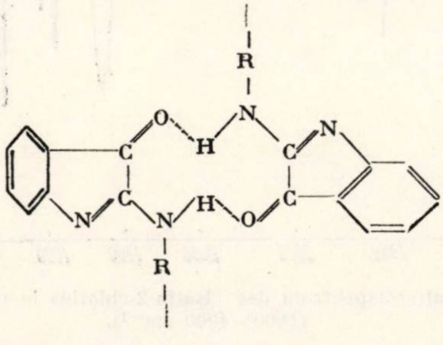
2-Arylamino-indoxyle weisen im Bereich 1200—1320 cm^{-1} zwei im allgemeinen intensive Banden auf, welche den Valenzschwingungen C—N zugesprochen werden können. Solche Schwingungen für aromatische Amine beispielsweise sind allgemein für ein Band im Bereich 1250—1360 cm^{-1} verantwortlich, welches um so mehr nach höheren Wellenlängen verschoben wird, je stärker die Bindung einen Doppelbindungscharakter aufweist. In unserem Falle ist es sehr wahrscheinlich, daß infolge der sehr bedeutenden Konjugation zwischen dem Indoxyl-System und den unbeteiligten Elektronen des Stickstoffatoms das Band zwischen 1230—1320 cm^{-1} der Bindung Stickstoff-Indoxyl entspricht. Das Band zwischen 1190—1200 cm^{-1} ist wahrscheinlich der Bindung Stickstoff-aromatisches System zuzuschreiben.

---

[5] J. Kebrle und K. Hoffmann, *Helv. chim. Acta*, **39**, 116 (1956).

Im Bereich 3270–3400 cm^{-1} weisen alle untersuchten Spektren ein oder zwei sehr breite Banden auf, welche auf durch Protonbindungen assozierte N–H Gruppen hinweisen. Wie aus Tabelle 1 und Vergleich der Abbildungen 1 und 2 hervorgeht, können alle untersuchten Verbindungen von diesem Standpunkt in zwei Kategorien eingeteilt werden. Einerseits weisen alle Verbindungen ein äußerst breites Band auf, welches bei cca. 2500 cm^{-1} anfängt und bei 3400 cm^{-1} ein Maximum besitzt. Dieses Band ist auf N–H-Gruppen mit verschiedenem Assozierungsgrad zurückzuführen, von freien Gruppen dieser Art welche im allgemeinen bei 3450 – 3490 cm^{-1} ersichtlich werden, bis zu solchen mit relativ kräftiger Assozierung.

Anderseits weisen ein Teil der besprochenen Verbindungen und zwar IV, VII, VIII und in geringerem Maße IX, also diejenigen, die von paradisubstituierten Aminen abstammen, neben dem obengenannten Band, ein zweites gleichfalls breites Band um 2850 cm^{-1} auf. Dieses weist auf eine sehr stark assozierte N–H Bindung hin, welche bei einfachen Aminen oder Amidinen natürlicherweise nicht auftritt. Sie wird aber häufig bei Systemen, welche die Fähigkeit besitzen doppelte Protonbindungen zu bilden, angetroffen. Solche Bindungen können in unserem Falle höchstwahrscheinlich folgendermaßen formuliert werden:



Die von metasulbstituierten Aminen oder Diaminoanthrachinone abstammenden Verbindungen können aus anscheinend sterischen Gründen solche Protonbindungen nicht bilden.

b) 3-ARYLIMINO-OXINDOLE

Die untersuchten 3-Arylimino-oxindole wurden durch die Reaktion des 3,3-Dichlorisatins mit aromatischen Diaminen, [2] wie auch durch direkte Kondensation des Isatins mit aromatischen Diaminen in Gegenwart von Polyphosphorsäure, [1] hergestellt. Die auf den zwei Synthesewegen erhaltenen Produkte sind identisch wie es aus dem Vergleich der IR-Spektren der beiden Derivate des *p*-Phenylendiamins ersichtlich wird (Abb. 4).

In Tabelle 2 werden die dem Oxindol-System charakteristischen wichtigsten Banden aufgeführt, welche über die Struktur der untersuchten

Verbindungen Aufschluß geben sollen.

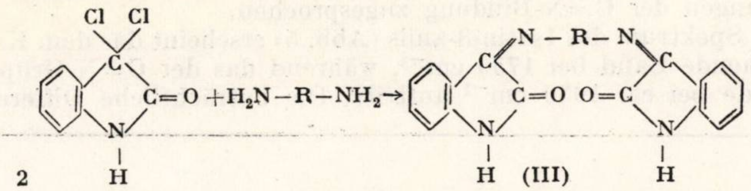


Tabelle 2

Die wichtigsten Banden des 3-Aryliminooxindol-Systems in Verbindungen der Struktur III

Symbol	Diamin entsprechend R aus Struktur III	Valenzschwingungen entsprechend (cm⁻¹)			
		C=O	C=N	N−H	C−N
XII	1,4-Phenylendiamin	1730	1710	3400 3200	1300, 1240 1200
XIII	Benzidin	1710	1710	3400 3200	1300, 1240 1200
XIV	*o*-Tolidin	1720	1710	3370 3200	1300, 1250

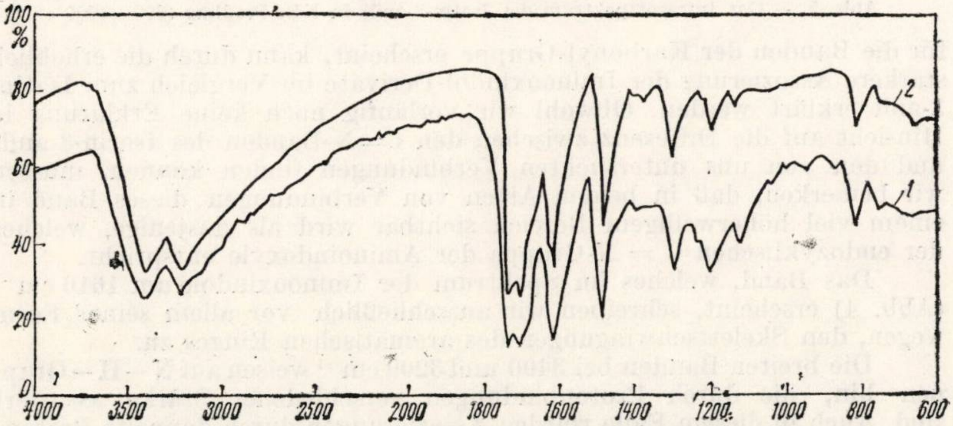

Abb. 4. — Die Infrarotspektren des Bis-(Indolin-2-on-3-yliden)-phenylendiamins-1,4 in KBr-Preßlingen (600−4000 cm⁻¹) erhalten durch:

1, Reaktion des 3,3-Dichlorisatins mit *p*-Phenylendiamin; *2*, direkte Kondencation des Isatins mit *p*-Phenylendiamin.

Das Oxindol und seine verschieden substituierten Derivate weisen ein Band im Bereich 1710−1740 cm⁻¹ auf, welches der Ketongruppe zugesprochen wird,[6−9] wodurch seine Keton-Struktur bestätigt wird.

In unserem Falle, erscheint dieses Band im gleichen Bereich jedoch viel breiter, woraus man das Vorhandensein eines Dubletts klar ersehen kann (Abb. 4). Wir haben das Maximum um 1710−1730 cm⁻¹ den Schwin-

---

[6] E. Wenkert, A. K. Bose und T. L. Reid, *J. Amer. Chem. Soc.*, **75**, 5514 (1953).
[7] A. Kellie, D. G. O'Sullivan und P. W. Sadler, *J. Chem. Soc.*, **1956**, 3809.
[8] H. E. Baumgarten und P. L. Creger, *J. Amer. Chem. Soc.*, **82**, 4634 (1960).
[9] H. E. Baumgarten, P. L. Creger und R. L. Zey, *J. Amer. Chem. Soc.*, **82**, 3977 (1960).

gungen des Karbonyls, während dasjenige bei 1710 cm^{-1} den Valenzschwingungen der C=N-Bindung zugesprochen.

Im Spektrum des Isatin-3-anils (Abb. 5) erscheint das dem Karbonyl entsprechende Band bei 1750 cm^{-1}, während das der C=N-Gruppe entsprechende bei ca. 1650 cm^{-1} auftritt. Die beträchtliche Differenz, die für die Banden der Karbonyl-Gruppe erscheint, kann durch die erheblich stärkere Assozierung der Iminooxindol-Derivate im Vergleich zum Isatin-3-anil erklärt werden. Obwohl wir vorläufig noch keine Erklärung in Hinsicht auf die Differenz zwischen den C=N-Banden des Isatin-3-anils und den von uns untersuchten Verbindungen finden können, müssen wir bemerken, daß in beiden Arten von Verbindungen dieses Band in einem viel höherwelligem Bereich sichtbar wird als dasjenige, welches der endozyklischen C = N-Gruppe der Aminoindoxyle entspricht.

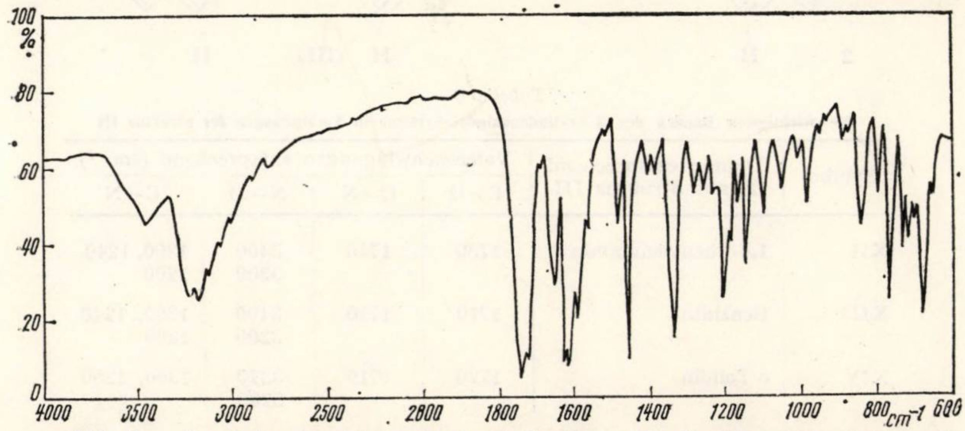

Abb. 5. — Das Infrarotspektrum des Isatin-3-anils in KBr-Preßling (600—4000 cm^{-1}).

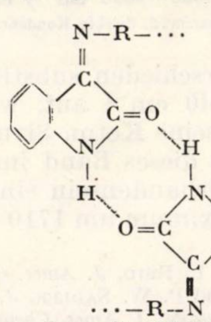
Das Band, welches im Spektrum der Iminooxindole um 1610 cm^{-1} (Abb. 4) erscheint, schreiben wir ausschließlich vor allem seiner Form wegen, den Skelettschwingungen des aromatischen Ringes zu.

Die breiten Banden bei 3400 und 3200 cm^{-1} weisen auf N—H—Gruppen hin, die durch Protonbindungen verschiedener Stärke assoziert sind. Auch in diesem Falle wurden Assozierungen durch doppelte Protonbindungen für die Schwingungen um 3200 cm^{-1} verantwortlich gemacht:



Den Valenzschwingungen der C—N-Bindung wurde eine Gruppe von Banden zwischen 1300 und 1200 cm^{-1} zugesprochen.

Revue Roumaine de Chimie, **18**, *2*, 283–288 (1973)

MATRIZIELLE CHARAKTERISIERUNG DER STRUKTUR UND TOPOLOGIE DER ORGANISCHEN VERBINDUNGEN. I

KONSTITUTION

F. KEREK und I. MOŢOC

Aus dem Organisch-chemischen Laboratorium des
Polytechnischen Instituts „Traian Vuia"
Timişoara Postfach 103

Eingegangen am 22. Juni 1972

Es wird für die Beschreibung der Konstitution der einfachen organischen Verbindungen ein Matrix-Formalismus verwendet. Analog mit den gewöhnlichen Matrizen war es möglich, eine Konstitutionsmatrix als Summe der Elementenmatrizen zu schreiben. Die verwendete Matrix erlaubt einen einfachen mathematischen Ausdruck der Bedingungen der Konstitutionsisomerie und verschiedener diesbezüglicher Probleme.

1. EINLEITUNG

Man kennt zahlreiche Versuche, die Struktur und einige Eigenschaften der organischen Verbindungen mathematisch zu beschreiben. In diesem Sinne verdienen jene erwähnt zu werden, die eine systematische Klassifizierung zum Gegenstand haben, [1] oder jene die die Einführung von Daten in die Computern verfolgen, [2] oder andere dieser Art. [3]

Eine besondere Kategorie stellen die verschiedenen Versuche dar, in der Chemie bekannte mathematische Formalismen anzuwenden, wie zum Beispiel die Graphentheorie, [4,5] die Topolgie [6–8] und andere, [9,10] mit welchen man eine genauere Ausdrucksweise der zahlreichen chemischen Phänomene anstrebt.

[10] E. Ruch und A. Schönhofer, *Theor. Chim. Acta*, **10**, 91 (1968); E. Ruch, *Theor. Chim. Acta*, **11**, 183 (1968).

Eine dritte Kategorie von Autoren versucht grundlegend neue Lösungen zu diesem Problem zu finden. Hierzu gehören in erster Reihe Ugi und seine Mitarbeiter, [11,12] welchen, unter Anwendung einiger Elemente der modernen Mathematik (Mengen, Topologie, usw.), die Ausarbeitung eines allgemein anwendbaren Klassifikations- und Nomenklatursystems gelang.

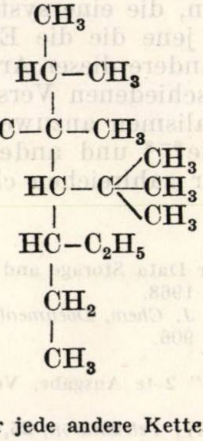
Unsere Arbeit stellt einen Versuch dar, die Konstitution sowie die Topologie der Moleküle organischer Verbindungen in einer matriziellen Sprachweise auszudrücken, einschließlich die wichtigsten stereoisomerischen Beziehungen.

2. KONSTITUTIONSMATRIZEN

Durch die Adoptierung einer einheitlichen Symbolisierung der verschiedenen Strukturelemente können wir jeder chemischen Verbindung eine Matrix $\mathfrak{M}$ zuordnen, welche deren Konstitution eindeutig darstellt.

Zur Veranschaulichung werden wir zuerst die matrizielle Darstellung im konkreten Fall eines azyklischen Kohlenwasserstoffes: 2,3,3-Trimethyl-5-äthyl-4-t-butyl-heptan (I) zeigen, und anschließend die Verallgemeinerungsmöglichkeiten dieser Methode.

Bezeichnen wir mit 1 ein Kohlenstoffatom (mit 0 ÷ 3 Wasserstoffatomen), mit O ein Wasserstoffatom, mit 2,3, usw. die Radikale Äthyl-, Propyl- usw., während $\bar{3}$, $\bar{4}$ die entsprechenden iso-Formen darstellen, so kann die Konstitution obiger Verbindung (I), in Bezugnahme auf die Hauptkette * (nach der Nomenklatur IUPAC [13]) mit Hilfe folgender Matrix $\mathfrak{M}$, vom Typ n×3 wiedergegeben werden:



$$\mathfrak{M}(\mathrm{I}) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 1 & 1 \\ 0 & 1 & 4 \\ 0 & 1 & 2 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{bmatrix} \qquad M_{42} = \bar{4} = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix} \qquad M_{52} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \end{bmatrix} \qquad (\mathrm{I})$$

---

* oder jede andere Kette.

[11] I. Ugi, D. Marquarding, H. Klusacek, G. Gokel und P. Gillespie, *Angew. Chem.*, **82**, 741 (1970).

[12] P. Gillespie, P. Hoffman, H. Klusacek, D. Marquarding, S. Pfohl, F. Ramirez, E. A. Tsolis und I. Ugi, *Angew. Chem.*, **83**, 691 (1971).

[13] „IUPAC Nomenclature of Organic Chemistry". 1957, Butterworths, London, 1958.

Für die Substituenten dieser Kette, mit drei oder mehreren Kohlenstoffatomen, ergibt sich, ebenfalls in der ausführlichen matriziellen Schreibungsform, eine sekundäre Matrix, wie es zum Beispiel $\overline{4}$ im obigen Beispiel ist *.

Verallgemeinernd können wir also sagen, daß man einer bestimmten organischen Verbindung eine Matrix $\mathfrak{M}$ zuordnen kann, welche eindeutig ihre Konstitution beschreibt. Für besondere Fälle kann man von der Matrix $n \times 3$ zur Matrix $n \times 1$ oder $n \times 2$ durch Partition übergehen.

Je nach der Art der Kette (Haupt- oder Nebenkette) welcher man die Matrix zuordnet, d.h. also in Bezugnahme auf die Restriktionsbedingungen welche bei ihrer Konstruktion gestellt wurden, unterscheidet man zwei Typen von Matrizen von der Form $n \times 3$:

i) Die Matrix $\mathfrak{M}$-Hauptmatrix, welche die Konstitution des Moleküls in Bezugnahme auf die Hauptkette charakterisiert. In der entwickelten Form (siehe Beziehung (3)) beschreibt sie aber eindeutig die Konstitution des gesamten Molekülaufbaues.

ii) Die Matrizen M, sekundäre genannt, welche Nebenmatrizen[14-17] der Matrix $\mathfrak{M}$ sind. Weil auch die Elemente einer Matrix M Nebenmatrizen vom Typ M sein können, kommen wir überein, einen zusätzlichen Begriff zu definieren, und zwar: Die Spezies k einer Konstitutionsmatrix. Die Spezies der Matrix $\mathfrak{M}$ ist, laut Definition, gleich mit 1 ($k = 1$). Die Elemente der Matrix $\mathfrak{M}$ zerlegt man in Matrizen vom Spezies 2 ($k = 2$), die man mit ${}^2M$ bezeichnet. Die Elemente der Matrix ${}^2M$ zerlegt man in ${}^3M$, usw. Im allgemeinen: M ist vom Spezies k (${}^kM$), wenn sie in der Matrix vom Spezies $k - 1$ (${}^{k-1}M$) Element ist.

Die Matrix $\mathfrak{M}$ besteht also aus:

$$\mathfrak{M} = \begin{bmatrix} {}^2M_{11} & 1 & {}^2M_{12} \\ \cdots & \cdots & \cdots \\ {}^2M_{l1} & 1 & {}^2M_{l2} \\ \cdots & \cdots & \cdots \\ {}^2M_{n^11} & 1 & {}^2M_{n^12} \end{bmatrix}$$

Man kann erkennen, daß $\mathfrak{M}$ die Matrix darstellt, die der Hauptkette (bestehend aus n^1 Kohlenstoffatomen) des Kohlenwasserstoffes oder dessen Derivate zugeordnet ist. Die Matrix $\mathfrak{M}$ kann man als folgende Summe schreiben:

$$\mathfrak{M} = \sum_{\text{alle } (l,p)} {}^2M_{lp} \, {}^{n^1}m_{lp} + {}^{n^1}m_{00} \tag{1}$$

---

* **Übereinkunftsgemäß vernachlässigt man die Zeilen 0 0 0, welche vor der ersten Zeile der Matrizen $\mathfrak{M}$ und M stehen müßten, bzw. nach der letzten Zeile der Matrix $\mathfrak{M}$ folgen müßten.**

[14] G. Cohen, „Eléments de Calcul Matriciel, à l'usage des E.N.S.A.M. et Ecoles d'Ingénieurs", Dunod, Paris, 1962.

[15] D. Michal, „Matrice and Tensor Calculus", Wiley, New York, 1966.

[16] H. Schwerdtfeger, „Introduction to Linear Algebra and Theory of Matrices", Verlag Noordhoff, Groningen, 1950.

[17] D. Pham, „Techniques du calcul matriciel", Verlag Dunod, Paris, 1962.

Es wird die folgende Zerlegungsweise gewählt [13-16]:

$$\mathfrak{M} = {}^2M_{11}\begin{bmatrix} 1 & 0 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 0 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 0 & 0 \end{bmatrix} + {}^2M_{12}\begin{bmatrix} 0 & 0 & 1 \\ \cdots & \cdots & \cdots \\ 0 & 0 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 0 & 0 \end{bmatrix} + {}^2M_{n1}\begin{bmatrix} 0 & 0 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 0 & 0 \\ \cdots & \cdots & \cdots \\ 1 & 0 & 0 \end{bmatrix} +$$

$$+ {}^2M_{n2}\begin{bmatrix} 0 & 0 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 0 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 0 & 1 \end{bmatrix} + \begin{bmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 1 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 1 & 0 \end{bmatrix} \qquad (2)$$

Es folgt aus der Gleichheit von (1) mit (2), daß:

$$^{n1}m_{00} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 1 & 0 \\ \cdots & \cdots & \cdots \\ 0 & 1 & 0 \end{bmatrix}$$

Andererseits sind ${}^{n1}m_{lp}$ Matrizen, die alle Elemente gleich Null haben, außer dem Element (l, p), das gleich 1 ist. Man kann diese Zerlegung der Matrix $\mathfrak{M}$ in einer allgemein gültigen Form schreiben:

$$\mathfrak{M} = {}^{n1}m_{00} + \sum_{\text{alle }(l,\,p)} \sum_{\text{alle }k} \sum_{\text{alle }(l',\,p')} ({}^{k+1}M_{l'p'} \cdot {}^{k+1}m_{l'p'}) \cdot {}^{n1}m_{lp} \qquad (3)$$

wo: $l = 1, 2, \ldots, n;$ $\quad p = 1, 2$

$l' = 1, 2, \ldots, n;$ $\quad p' = 1, 2$

$k = 1, 2, \ldots;$

die gegebene Werte annehmen können.

Für das Hervorheben eines bestimmten Liganden (l_0, p_0) der Hauptkette C_{n^1} benützt man die folgende Zerlegungsweise :

$$\mathfrak{M} = {}^{1n}m_{00} + \sum_{(lp)\neq(l_0p_0)} {}^2M_{lp}\cdot{}^{n^1}m_{lp} + {}^2M_{l_0p_0}\cdot{}^{n^1}m_{l_0p_0} \tag{4}$$

Eine konkrete Anwendung der Gleichung (3) auf die Verbindung (II) führt uns zu dem Ausdruck (5) :

$$CH_3-C(CH_3)_2-CH_2-CH[C(CH_3)_3]-(CH_2)_2-CH_3 \tag{II}$$

$$\begin{aligned}\mathfrak{M} = {}&{}^7m_{00} + {}^7m_{21} + {}^7m_{22} + {}^7m_{42}\cdot({}^2m_{00} + {}^2m_{21} + {}^2m_{22} + 0\cdot{}^2m_{11} + 0\cdot{}^2m_{12}) + \\ &+ 0\cdot({}^7m_{11} + {}^7m_{12} + {}^7m_{31} + {}^7m_{32} + {}^7m_{51} + {}^7m_{52} + {}^7m_{61} + {}^7m_{62} + \\ &+ {}^7m_{71} + {}^7m_{72}).\end{aligned} \tag{5}$$

Im Falle der Verbindung (III) erhält man den Ausdruck (6) :

$$CH_3-C(CH_3)_2-C[C(CH_3)_3]_2-C(CH_3)_2-CH_3 \tag{III}$$

$$\begin{aligned}\mathfrak{M} = {}&\begin{bmatrix} 0 & 1 & 0 \\ 1 & 1 & 1 \\ 4 & 1 & 4 \\ 1 & 1 & 1 \\ 0 & 1 & 0 \end{bmatrix} = {}^5m_{00} + {}^5m_{21} + {}^5m_{22} + {}^5m_{41} + {}^5m_{42} + ({}^5m_{31} + {}^5m_{32})\cdot \\ &\cdot({}^2m_{00} + 0\cdot{}^2m_{11} + 0\cdot{}^2m_{21} + 0\cdot{}^2m_{12} + {}^2m_{21} + {}^2m_{22}) + \\ &+ 0\cdot({}^5m_{11} + {}^5m_{21} + {}^5m_{41} + {}^5m_{42}).\end{aligned} \tag{6}$$

3. KONSTITUTIONSISOMERIE

Die matrizielle Behandlung der Konstitutionsisomerie besteht in der Bestimmung der Bedingungen, unter welchen man die Matrix $\mathfrak{M}$ und die Matrizen M aufbaut.

In der folgenden Ausführung stellen (lp), $(l'p')$ die Elemente aus den Positionen (lp), beziehungsweise $(l'p')$ dar. Wir werden nun die Kettenisomerie im Alkan $C_x H_{2x+2}$ $(x = 1, 2, \ldots)$ behandeln :

Die erste Isomeriebedingung ist :

$$\sum_{l=1}^{n^1}\sum_{p=1}^{2}(l,p) = x - n^1 \tag{7}$$

$$\sum_{l'=1}^{k+2_n}\sum_{p'=1}^{2}(l',p') = {}^k(l'\,p') - {}^{k+1}q \tag{8}$$

In diesen Beziehungen stellen n^1 und q die Dimensionen der Haupt- beziehungweise der sekundären Matrizen dar. Mit ${}^k(l'p')$ wurde das Element $(l'p')$ aus der Matrix M der Spezies k bezeichnet. Die nächste Bedingung ist tatsächlich ein mathematischer Ausdruck der IUPAC-Nomenklaturkonvention [17] bezüglich der Länge der Haupt- und Nebenketten. Es wird gezeigt, daß die Länge der Nebenkette, die vom Zentrum j abzweigt, folgende zwei Bedingungen erfüllen muß:

a.) Für die Matrix $\mathfrak{M}$:

$$ {}^1j - 1 \geqslant {}^2q \leqslant {}^1n - ({}^1j + 1). \tag{9}$$

In der obigen Ungleichung ziehen wir das Gleichheitszeichen in Betracht, wenn:

$a - 1$: die Anzahl der Elemente $(lp) \neq 0$ der Nebenmatrix $(>j) \times 3$ ist.

$a - 2$: die Anzahl der Elemente $(lp) \neq 0$ der Nebenmatrix $(<j) \times 3$ größer oder gleich mit der Anzahl der Elemente $(l'p') \neq 0$ der Matrix $q \times 3$ ist.

b.) Für die Matrizen M:

$$ {}^kj - 1 \geqslant {}^{k+1}q. \tag{10}$$

Die Bedingung, in welcher in obiger Beziehung auch das Gleichheitszeichen gültig wird, ist jene, die oben mit $a - 1$ bezeichnet wurde.

Dank der Existenz der gleichwertigen Stellungen auf einer Hauptkette beschreiben zwei Matrizen die gleiche chemische Konstitution wenn:

$$\begin{bmatrix} {}^2M_{11} & 1 & {}^2M_{12} \\ \cdot\;\cdot\;\cdot & \cdot\;\cdot\;\cdot & \cdot\;\cdot\;\cdot \\ {}^2M_{n^11} & 1 & {}^2M_{n^12} \end{bmatrix} = \begin{bmatrix} {}^2M_{n^11} & 1 & {}^2M_{n^12} \\ \cdot\;\cdot\;\cdot & \cdot\;\cdot\;\cdot & \cdot\;\cdot\;\cdot \\ {}^2M_{11} & 1 & {}^2M_{12} \end{bmatrix} \tag{11}$$

Andere Möglichkeiten, die zur Gleichwertigkeit der Matrizen führen würden, schließt man durch folgende Bedingungen (12) aus:

$$\begin{aligned} (l\ 1) &< (l\ 2); \quad & l &= 1, 2, \ldots, n^1 \\ (l'\ 1) &< (l'\ 2); \quad & l' &= 1, 2, \ldots, q. \end{aligned} \tag{12}$$

Die Bestimmung der Anzahl der Kettenisomere einer chemischen Verbindung besteht also darin, die Anzahl der nichtgleichwertigen Matrizen $\mathfrak{M}$, die ihr zugeordnet wurden, zu finden.

4. SCHLUSSFOLGERUNGEN

Der hier vorgeschlagene Matrix-Formalismus der Konstitution einfacher organischer Verbindungen erlaubt eine anschauliche Ausdrucksweise der dazugehörigen Probleme. Unter anderen, scheint diese Schreibweise versprechend für die Computereinführung von Konstitutionsdaten, sowie auch für eine mathematische Formulierung der wichtigsten topologischen Beziehungen, die sich gegenwärtig noch in ihrer Ausarbeitung befindet.

MATRIZIELLE CHARAKTERISIERUNG DER STRUKTUR UND TOPOLOGIE ORGANISCHER VERBINDUNGEN. II

KONFIGURATION, CHIRALITÄT

I. MOŢOC und F. KEREK
Aus dem Organisch-chemischen Laboratorium des
Polytechnischen Instituts „Traian Vuia"
Timişoara Postfach 103

Eingegangen am 22. Juni 1972

Für eine anschauliche mathematische Charakterisierung der molekularen Topologie wird eine kanonische Matrix vorgeschlagen. Diese, zusammen mit einigen Operatoren ($\mathcal{C}$, $\mathcal{L}$, *F*, *T*) erlauben eine einfache mathematische Ansdrucksweise des Verfahrens zur Bestimmung der molekularen Chiralität sowie der verschiedenen stereoisomeren Beziehungen. Beachtlich sind die Vergleiche zwischen dem mathematischen und chemischen Sinne dieser Gleichungen, wie zum Beispiel: die den enantiomeren Konfigurationen zugeordneten Matrizen stehen im Verhältnis Matrix-transponierte Matrix.

1. EINLEITUNG

In unserer vorhergehenden Arbeit [1] wurden die Prinzipien der matriziellen Beschreibung der Konstitution organischer Verbindungen dargelegt. Im folgenden wird versucht, dieselbe mathematische Methode in der Beschreibung der topologischen Eigenschaften der Moleküle anzuwenden.

Die chemische Topologie beschäftigt sich, laut Prelogs Definition, [2,3] mit den Eigenschaften der geometrischen Figuren, die mit der momentanen oder „time average" Topographie der chemischen Teilchen (also damit, was man gewöhnlich als räumliche Anordnung der Atome im Molekül bezeichnet) isomorph oder homöomorph sind.

In einer topologischen Behandlung eines Molekülaufbaus kommt den metrischen Parametern eine beschränkte Bedeutung zu, d.h. man operiert nicht in einem metrischen Raum. Jedoch auf diese Art und

---

[2] V. Prelog, Abstr. Roger Adams Award Lecture 1969, ACS Meeting, Salt Lake City, Utah.

[3] V. Prelog, *Chem. Brit.*, **4**, 382 (1968).

Weise erzielt man eine Verallgemeinerung der Probleme, denn der metrische Raum ist ein Sonderfall des afinen Raumes. [4]

Die Idee der topologischen Behandlung der Stereoisomerie und der damit zusammenhängenden Erscheinungen fand interessante Anwendungen. [5] Ebenso erzielte man spektakuläre experimentelle Beweise für einige „rein"-topologische Isomeriefälle. [6-9]

Besondere Beachtung in der Reihe der theoretischen Ausführungen verdienen die Arbeiten von Ruch und seinen Mitarbeitern. [10-12] Sie haben, unter anderen, eine umfassende Theorie der Chiralitätsfunktionen und der damit verbundenen Phänomene aufgestellt.

Arbeiten von grundlegender Bedeutung sind die kürzlich erschienenen Artikel von Ugi und Mitarbeiter, [13,14] welche die Thematik der Molekularstruktur behandeln, in einem sowohl den statischen als auch den dynamischen Problemen allgemein anwendbaren mathematischen Formalismus. Die Verfasser haben zu diesem Zweck Elemente der modernen Mathematik (Mengen, Gruppen, Permutationen usw.) erfolgreich verwendet.

Von Anfang an weisen wir darauf hin, daß diese Arbeit keine ähnliche, die Gesamtheit der strukturellen Probleme umfassende Behandlung beabsichtigt! Es wird versucht, nur eine einfache und anschauliche mathematische Struktur für die Charakterisierung der häufigsten Aspekte struktureller Beziehungen zu finden. Der Zweck einer solchen Umschreibung der chemischen Realität in mathematischen Modellen ist, mit diesen Modellen mathematische Operationen ausführen zu können, um nachher die entsprechenden Schlußfolgerungen mit Hilfe von chemischen Ausdrücken zu erläutern.

Es sei noch hinzugefügt, daß die Behandlung der mit der Stereoisomerie zusammenhängenden Beziehungen, nur auf die topologischen Aspekte der Probleme beschränkt wird. Ebenso wird es einfachheitshalber in jedem Fall versucht, die in Betracht gezogenen strukturellen Elemente, nach Möglichkeit, auf ein Minimum zu beschränken. Mit anderen Worten, es werden nur jene strukturellen Elemente behandelt, die eine bestimmte Rolle in der analysierten Struktureinheit haben.

Es ist möglich, daß die Anwendung des matriziellen Formalismus in einigen besonderen Fällen, infolge der Vereinfachungstendenz weniger erfolgreich sein wird.

2. KONFIGURATION

2.1. DEFINITION. ALLGEMEINE BETRACHTUNGEN

Zahlreiche Verfasser haben in letzter Zeit auf das Fehlen einer vollkommenen, zufriedenstellenden Definition des Begriffes der Konfiguration, beziehungsweise der Konformation hingewiesen. [15–17]

Es ist in diesem Rahmen nicht angebracht, die verschiedenen Seiten dieser Problematik zu behandeln. [18] Trotzdem ist es notwendig, den Sinn, in dem die betreffenden Begriffe im folgenden verwendet werden, klarzulegen.

Im Rahmen einer auf topologische Aspekte beschränkten Behandlung muß die *Konfiguration* als ein topologisches Modell der relativen räumlichen Anordnung der Liganden in bezug auf ein Strukturelement betrachtet werden, ohne die verschiedenen, durch relative Torsionsbewegungen um internukleare Achsen des Moleküls erzeugbaren Varianten, in Betracht zu ziehen.

Für die folgenden Ausführung werden die, durch solche Drehungen erhaltenen und geläufig als *Konformationen* bezeichneten Varianten, ebenfalls vom topologischen Standpunkt aus betrachtet.

Das Problem der Molekularchiralität spielt natürlich im Rahmen der Gesamtheit der stereoisomeren Beziehungen eine grundlegende Rolle. Wir übernehmen die Definition des Begriffes in dem von Kelvin gegebenen Sinn (1904), [19] mit der Bemerkung, daß wir uns in erster Reihe auf die geläufigen, d.h. auf die von Ruch und Mitarbeiter mit *a* bezeichneten Typen von Molekularchiralität beziehen.

Zu Beginn werden wir die Konvention zur Spezifikation der zentralen Chiralität nach Cahn, Ingold und Prelog [20] vom mathematischen Standpunkt aus behandeln, da sie eine grundlegende Bedeutung in der Diskussion der mit der Chiralität zusammenhängenden chemischen Aspekte hat.

2.2. DAS CAHN, INGOLD, PRELOG-VERFAHREN ZUR BESTIMMUNG DER MOLEKULAREN CHIRALITÄT

Dieses Verfahren umfaßt eigentlich folgende Teile :

— Ein Set von Instruktionen, welche die prioritäre Ordnung der Liganden festlegen und zusammenfassend als Standard-Sequenzregel bekannt sind, die wir künftighin mit I bezeichnen werden.

— Die Instruktionen, welche die konventionelle Betrachtungsweise des Chiralitätselements betreffen, die wir mit *K* bezeichnen werden.

---

[15] R. S. Cahn und V. Prelog, „Report on Symposium, on Stereochemical Concepts and Nomenclature", London 1968.

[16] IUPAC Tentative Rules for the Nomenclature of Organic Chemistry Section E. Fundamental Stereochemistry, *J. Org. Chem.*, **35**, 2849 (1970).

[17] * * * *Nachr. Chem. Techn.*, **17**, 443 (1969).

[18] G. Ostrogovich und F. Kerek, „Kompendium der Elemente der Stereochemie", Polytechnisches Institut Timişoara, 1971.

[19] „Chiral heißt jede geometrische Figur, die mit ihrem Spiegelbild nicht kongruent ist", Lord Kelvin, Baltimore Lectures (1884); L. Whyte, *Nature*, **180**, 513 (1957); **182**, 198 (1958).

[20] R. S. Cahn, C. K. Ingold und V. Prelog, *Angew. Chem.*, **78**, 413 (1966).

In Funktion von diesen Bedingungen kann der Sinn der Chiralität in jedem Fall eindeutig als *R* (rectus) oder *S* (sinister), beziehungsweise als *P* (plus) oder *M* (minus) bestimmt werden.

2.3. STANDARD-SEQUENZREGEL

Die Spezifikation des Sinnes der Chiralität drängt in jedem Fall die Differenzierung der Liganden eines Chiralitätszentrums auf, deren Anzahl $\mathcal{N}$ gewöhnlich zwischen 2 und 6 liegt : $2 \leqslant \mathcal{N} \leqslant 6$.

Ganz allgemein gesehen, kann man von der Menge der möglichen Liganden $\overline{\psi}$ sprechen :

$$\overline{\psi} = \{\psi_N\} \qquad (N = 1, 2, \ldots, \infty)$$

Die Menge aller möglichen Liganden $\overline{\psi}$ ist unendlich und zählbar. Laut der Standard-Sequenzregel können wir den nichtidentischen Elementen ψ dieser Menge $[\psi \in \overline{\psi}]$ Indices N zuordnen. Die Zuordnung des Index N erzielt man durch eine isomorphe Abbildung, d.h. einem gegebenen Liganden entspricht ein einziger Index. Da die Menge N der natürlichen Zahlen aufgrund der Beziehung „ist größer" (d.h. $>$) vollkommen geordnet ist, wird auch die Menge $\overline{\psi}$ durch die isomorphe Natur der Abbildung total geordnet sein.

$$N > N' \text{ bedeutet, daß auch } \psi_N > \psi_{N'} \tag{I}$$

3. CHARAKTERISIERUNG DER KONFIGURATION DURCH EINE KANONISCHE MATRIX

Von topologischem Standpunkt aus ist die Konfiguration eines Strukturelements durch die relative räumliche Anordnung der diesem Element zugeordneten Liganden definiert.

Für gewöhnliche organische Verbindungen bleibt die Zahl der Liganden, die eine definierende Rolle für den Sinn der Konfiguration haben, begrenzt, und zwar : $2 \leqslant \mathcal{N} \leqslant 4$.

Alle diese Liganden gehören der vollkommen geordneten Menge $\overline{\psi}$ an. Im Falle von vier, einem Chiralitätselement zugeordneten Liganden ist die Anordnung derselben in einer Matrix vom Typ 2×2 anschaulich und vorteilhaft dargestellt :

$$M^* = \begin{bmatrix} \psi_{11} & \psi_{12} \\ \psi_{21} & \psi_{22} \end{bmatrix} \qquad \psi_{ij} \in \overline{\psi} \ (i, j = 1, 2) \tag{1}$$

Um eine eindeutige Beziehung zwischen der chiralen Struktur und der zugeordneten Matrix herzustellen sind die folgenden Bemerkungen besonders notwendig :

— Der Ligand letzten Ranges nach der Standard-Sequenzregel (I) nimmt die Position ψ_{22} in der Matrix M^* ein.

— Die Hauptdiagonale der Matrix stellt die entfernteste Kante des Tetraeders dar (Bedingung *K* von Cahn, Ingold und Prelogs Verfahren). Abbildung (1) veranschaulicht diese zwei Konventionen:

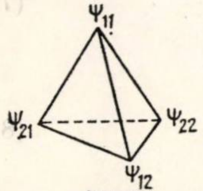

Abb.(1)

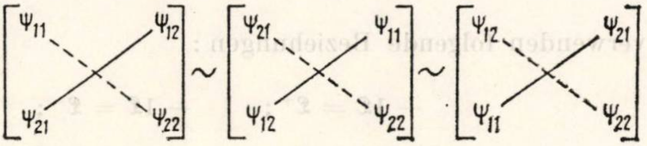


$$\begin{bmatrix}\psi_{11} & \psi_{12}\\ \psi_{21} & \psi_{22}\end{bmatrix} \sim \begin{bmatrix}\psi_{21} & \psi_{11}\\ \psi_{12} & \psi_{22}\end{bmatrix} \sim \begin{bmatrix}\psi_{12} & \psi_{21}\\ \psi_{11} & \psi_{22}\end{bmatrix} \qquad (2)$$

Zieht man das Element ψ_{22} letzten Ranges $\equiv 0$ in Betracht, dann erhalten obige Matrizen folgende kanonische Form *M*:

$$M = \begin{bmatrix}\psi_{11} & \psi_{12}\\ \psi_{21} & 0\end{bmatrix} \quad M' = \begin{bmatrix}\psi_{21} & \psi_{11}\\ \psi_{12} & 0\end{bmatrix} \quad M'' = \begin{bmatrix}\psi_{12} & \psi_{21}\\ \psi_{11} & 0\end{bmatrix} \qquad (3)$$

Alle drei Matrizen beschreiben ein und dieselbe Konfiguration, wie das im folgenden gezeigt wird.

3.1. SPEZIFIKATION DER ZENTRALEN CHIRALITÄT

Wir definieren einen Operatoren $\mathcal{C}^\varphi$ mit folgenden Eigenschaften:

$$\mathcal{C}^1 M = M' \quad \mathcal{C}^2 M = \mathcal{C}^1 M' = M'' \quad \mathcal{C}^1 M'' = M \qquad (4)$$

$$M = \mathcal{C}^0 M = \mathcal{C}^2 M' = \mathcal{C}^1 M''$$

d.h. verallgemeinert:

$$\mathcal{C}^\varphi a = a \qquad (a = \text{Skalar})$$

$$\mathcal{C}^\varphi = \mathcal{C}^1 \mathcal{C}^{\varphi-1} \longleftrightarrow \mathcal{C}^\varphi = \mathcal{C}^{\varphi-3k} \qquad (5)$$

wo: $k = 0, 1, \ldots$ und $\varphi \geqslant 3$.

Daraus folgt, daß der Operator $\mathcal{C}^\varphi$ eine zirkulare Permutation mit Elementen, die mit ψ_{22} nichtidentisch sind, und zwar im Uhrzeigersinn aufstellt.

Gegeben ist auch der Operator $\mathcal{L}$, der eine zirkuläre Permutation der Liganden ψ_{11}, ψ_{12}, ψ_{21} in der von der Standard-Sequenzregel dieser Liganden festgelegten Reihenfolge aufstellt. Man kann also schreiben:

$$\mathcal{C}^\varphi M = \lambda \mathcal{L} M. \qquad (6)$$

Aus der Beziehung (6) folgt, daß der Skalar λ die Werte $\lambda = \pm 1$ annimmt, d.h. jedwelche Matrix von chiraler Konfiguration erfüllt eine der folgenden Gleichungen :

$$\mathcal{C}^{\varphi} = \mathcal{L}\,; \qquad \mathcal{C}^{\varphi} = -\,\mathcal{L}\,; \tag{7}$$

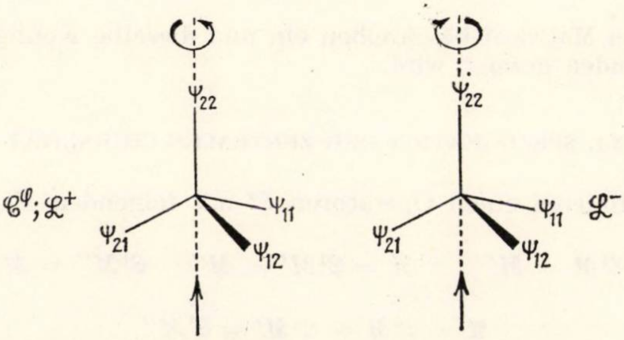
Wir verwenden folgende Beziehungen :

$$+\,1\mathcal{L} = \mathcal{L}^{+}\,; \qquad -\,1\mathcal{L} = \mathcal{L}^{-}\,; \tag{8}$$

Also werden die Gleichungen (7) :

$$\mathcal{C}^{\varphi} = \mathcal{L}^{+}\,; \qquad \mathcal{C}^{\varphi} = \mathcal{L}^{-}\,; \tag{9}$$

Wir bemerken, daß die Anwendung dieser Operatoren der Drehung der Verbindung um die Achse $C - \psi_{22}$ auf folgende zwei Arten gleichkommt :



Durch unmittelbares Berechnen kann man zeigen, daß :

$$\mathcal{C}^{\varphi}\mathcal{L}^{+} = \mathcal{L}^{+}\mathcal{C}^{\varphi} \qquad \mathcal{C}^{\varphi}\mathcal{L}^{-} = -\,\mathcal{L}^{-}\mathcal{C}^{\varphi}$$

$$\mathcal{L}^{+} = -\,\mathcal{L}^{-} \longleftrightarrow \mathcal{L}^{-} = -\,\mathcal{L}^{+}$$

Faßt man obige Eigenschaften zusammen, so :

$$\mathcal{C}^{\varphi}\mathcal{L}^{-} = -\,\mathcal{L}^{-}\mathcal{C}^{\varphi} = \mathcal{L}^{+}\mathcal{C}^{\varphi} = \mathcal{C}^{\varphi}\mathcal{L}^{+}$$

Man kann also behaupten, daß die Matrix M eine Konfiguration $R(M_R)$, beziehungsweise $S(M_S)$ definiert, je nachdem, ob sie die Gleichung :

$$\mathcal{C}^{\varphi}M_R = \mathcal{L}^{+}M_R$$

oder :

$$\mathcal{C}^{\varphi}M_S = \mathcal{L}^{-}M_S$$

erfüllt. Mit anderen Worten, verwirklicht die Teilung der Menge $\lambda = \{M\}$ in zwei Klassen (Untermengen), λ_R und λ_S, so daß:

$$\lambda_R U \lambda_S = \lambda; \qquad \lambda_R \cap \lambda_S = \Phi$$

Das heißt, daß λ_R und λ_S disjunkt sind, da es keine Matrix M gibt, die sowohl λ_R als auch λ_S angehört.

Gegeben sei nun eine Matrix M_R, d.h. $\mathfrak{C}^{\varphi} M_R = \mathfrak{L}^{+} M_R$. Gegeben ist auch M_R^T, die transponierte Matrix von M_R. Durch unmittelbares Berechnen findet man:

$$-\mathfrak{C}^{\varphi} M_R^T = \mathfrak{L}^{+} M_R^T$$

oder:

$$-[-\mathfrak{C}^{\varphi} M_R^T] = -\mathfrak{L}^{+} M_R^T \tag{10}$$

Das heißt:

$$\mathfrak{C}^{\varphi} M_R^T = \mathfrak{L}^{-} M_R^T \tag{11}$$

Also $M_R^T \in \lambda_S$, was soviel bedeutet wie: $M_R^T \equiv M_S$
Die Transponierung ($|^T$) führt zur Inversion der Konfiguration. Also die beiden Klassen von Konfigurationsmatrizen verwandeln sich eine in die andere durch die Transponierung ihrer Elemente.

Folglich stehen die den zwei enantiomeren Konfigurationen entsprechenden Matrizen im Verhältnis Matrix und ihre transponierte Matrix zueinander.

Für jede Konfigurationsmatrix M des Chiralitätszentrums eines Moleküls (mit einem einzigen Chiralitätszentrum) kann man folgende Chiralitätsgleichungen schreiben:

$$\mathfrak{C}^{\varphi} M = \mathfrak{L}^{+} M \qquad \mathfrak{C}^{\varphi} M^T F = \mathfrak{L}^{-} M^T F \tag{12}$$

oder:

$$\mathfrak{C}^{\varphi} M = \mathfrak{L}^{-} M \qquad \mathfrak{C}^{\varphi} M^T F = \mathfrak{L}^{+} M^T F \tag{13}$$

Mit F wurde folgende Matrix bezeichnet:

$$F = \begin{bmatrix} \delta & 0 \\ 0 & \delta \end{bmatrix}$$

wo δ der Operator ist, welcher folgende Operation ausführt:

$$[a_{ji}]\delta = [a_{ji}]^T = [a_{ij}]$$

F besitzt die Eigenschaft:

$$F.F = E$$

wo :

$$E = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

Aus den Gleichungen (12) und (13) folgt, daß die aufeinanderfolgende Anwendung der Operation F und beziehungsweise $|^T$ die Widerspiegelung des Moleküls in seiner Gesamtheit darstellt. Durch F wird die konfigurative Inversion der Liganden, durch die Transposition T aber wird dieselbe Operation beim betreffenden Zentrum erzielt.

SCHLUSSFOLGERUNGEN

Die Anwendung der matriziellen Struktur bei der Charakterisierung der Konfiguration ermöglichte die Festlegung einiger analytischer Ausdrücke (Gleichungen). Diese ermöglichen eine kurzgefaßte Beschreibung des Chiralitätssinnes, der Enantiomeriebeziehung im Falle der zentralen Chiralität.

Es ist wichtig zu bemerken, daß sich die matrizielle Beschreibung schon lange Zeit als beste Methode zur Beschreibung der Vektor- und Tensorprobleme bewährt hat. Diese Parallele erlaubt unter anderen, die verschiedenen Chiralitätserscheinungen als vektorielle Probleme zu betrachten.

Vorläufig werden wir in unserer folgenden Arbeit [21] die axiale, konformationelle Chiralität und andere spezielle Chiralitätsfälle betrachten.

MODERN FRIEDEL-CRAFTS CHEMISTRY. I

CYCLIALKYLATIONS OF SOME SECONDARY AND TERTIARY PHENYLALKYL CHLORIDES IN THE PRESENCE OF THE MILD $AlCl_3/CH_3NO_2$ AND $FeCl_3$ CATALYSTS

ALI ALI KHALAF

Department of Chemistry, Assiut University, Assiut,
Arab Republic of Egypt

Received July 26, 1972

Chlorides (1) through (8) were prepared and their reactions in the presence of $AlCl_3/CH_3NO_2$ and $FeCl_3$ catalysts were investigated. In the presence of these mild catalysts, the chlorides underwent clean cyclidehydrohalogenations to give the corresponding indans and tetralins in yields much better than those reported previously from the cyclidehydrations of the corresponding alcohols with either sulphuric or phosphoric acid. The results, in general, demonstrated that Fiedel-Crafts cyclialkylations provide a very useful simple method for preparing indan and tetralin derivatives.

In 1966, Khalaf and Roberts[1] investigated, among other things, the cyclialkylations of certain phenylalkyl chlorides in the presence of aluminum chloride as catalyst. Utilising modern instrumental methods of separation and identification, these authors recognized two important facts about these reactions: First, certain generalizations regarding the extent or lack of accompanying rearrangements that have been made by other workers[2] are too broad, and some of the experimental data upon which these generalizations were reached are virtually incorrect. Secondly, with the strong catalyst aluminum chloride, the cyclialkylation reactions were frequently accompanied by other side reactions, especially intermolecular polyalkylation and hydride exchange. For example, the latter reaction was held responsible for the formation of isopentylbenzene in the $AlCl_3$-catalyzed cyclization of both 2-chloro-2-methyl-4-phenylbutane and 1-chloro-2-methyl-4-phenylbutane and of isohexylbenzene in the cyclization of 2-chloro-2-methyl-5-phenylpentane[1]. These side reactions which result in the production of compounds with boiling points very close to those of the expected cyclic products place very serious limitations on the synthetic potentialities of these aluminum chloride-catalyzed cyclialkylations. For this reason, it was found of interest to study the utilization of mild catalysts such as $FeCl_3$ and $AlCl_3/CH_3NO_2$ complex in an attempt to eliminate or, at least, to minimize the observed undesirable side reactions. Frequently, the use of the mild $AlCl_3/CH_3NO_2$ catalyst has been shown to be advantageous, both in industrial processes and in laboratory syntheses, not only because it inhibits all the side reactions that are initiated by the abstraction of hydride ions,[3-8] but also because it has a uniform activity and a constant physical state.[9]

In the present work, the Friedel-Crafts cyclialkylations of the tertiary chlorides **1** to **6** and of the secondary chlorides **7** and **8** were investigated in the presence of both $AlCl_3/CH_3NO_2$ and $FeCl_3$ catalysts.

RESULTS AND DISCUSSION

The results of the cyclialkylation reactions of chlorides (**1**) through (**8**) are summarized in Table 1 and schematically in equations (A) to (H).

Table 1

Cyclialkylation Reactions of Secondary and Tertiary Phenylalkyl Chlorides in the Presence of $AlCl_3/CH_3NO_2$ and $FeCl_3$ Catalysts [a]

Exp. N°	Starting chloride (N°)	Catalyst	Solvent	Products	Yield[b] %
1	2-Chloro-2-methyl-4-phenylbutane (**1**)	$AlCl_3/CH_3NO_2$	P.E.[c]	1,1-Dimethylindan	79
2	2-Chloro-2-methyl-4-phenylbutane (**1**)	$AlCl_3/CH_3NO_2$	CS_2	1,1-Dimethylindan	60
3	2-Chloro-2-methyl-4-phenyl butane (**1**)	$AlCl_3/CH_3NO_2$	P.E.	1,1-Dimethylindan	65
4	2-Chloro-2-methyl-4-(*o*-tolyl)butane (**2**)	$AlCl_3/CH_3NO_2$	P.E.	1,1,4-Trimethylindan	75
5	2-Chloro-2-methyl-4-(*o*-tolyl)butane (**2**)	$FeCl_3$	P.E.	1,1,4-Trimethylindan	73
6	2-Chloro-2-methyl-4-(*m*-tolyl)butane (**3**)	$AlCl_3/CH_3NO_2$	P.E.	1,1,5-(56 %) and 1,1,7-trimethylindan (44 %).	70
7	2-Chloro-2-methyl-4-(*m*-tolyl)butane (**3**)	$FeCl_3$	P.E.	1,1,5-(60 %) and 1,1,7-trimethylindan (40 %)	65
8	2-Chloro-2-methyl-4-(*p*-tolyl)butane (**4**)	$AlCl_3/CH_3NO_2$	P.E.	1,1,6-trimethylindan	72

(continued)

Exp. N°	Starting chloride (N°)	Catalyst	Solvent	Products	Yield[b] %
9	2-Chloro-2-methyl-4-(*p*-tolyl)butane (**4**)	$FeCl_3$	P.E.	1,1,6-trimethylindan	68
10	2-Chloro-2-methyl-5-phenylpentane (**5**)	$AlCl_3/CH_3NO_2$	P.E.	1,1-Dimethyltetralin	74
11	2-Chloro-2-methyl-5-phenylpentane (**5**)	$FeCl_3$	P.E.	1,1-Dimethyltetralin	76
12	2-Chloro-2-methyl-6-phenylhexane (**6**)	$AlCl_3/CH_3NO_2$	P.E.	1-Isopropyltetralin	68
13	2-Chloro-2-methyl-6-phenylhexane (**6**)	$FeCl_3$	P.E.	1-Isopropyltetralin	65
14	3-Chloro-5-phenylpentane (**7**)	$AlCl_3/CH_3NO_2$	P.E.	1-Methyltetralin	75
15	3-Chloro-5-phenylpentane (**7**)	$FeCl_3$	P.E.	1-Methyltetralin	70
16	2-Chloro-5-phenylpentane (**8**)	$AlCl_3/CH_3NO_2$	P.E.	1-Methyltetralin	83
17	2-Chloro-5-phenylpentane (**8**)	$FeCl_3$	P.E.	1-Methyltetralin	76

[a] All reactions were carried out at room temperature for a total reaction time of one hour using the ratios specified in the experimental part.

[b] Determined by distillation in some cases and by vpc analysis using internal standards in some other cases.

[c] Petroleum ether (b.p. 60 – 80°).

As indicated in the experimental section, the results were obtained by treating the chlorides with mild $AlCl_3/CH_3NO_2$ and $FeCl_3$ catalysts in carbon disulphide and/or petroleum ether solvent at a room temperature of 25°.

From the results of Table 1, it can be seen that the $AlCl_3/CH_3NO_2$ and $FeCl_3$ treatments produced 1,1-dimethylindan (**10**) from 2-chloro-2-methyl-4-phenylbutane (**1**), 1,1,4-trimethylindan (**12**) from 2-chloro-2-methyl-4-(*o*-tolyl)butane (**2**), a mixture of 1,1,5- (**14**) and 1,1,7-trimethylindane (**15**) from 2-chloro-2-methyl-4-(*m*-tolyl)butane (**3**), 1,1,6-trimethylindan (**17**) from 2-chloro-2-methyl-4-(*p*-tolyl)butane (**4**) 1,1-dimethyltetralin (**19**) from 2-chloro-2-methyl-5-phenylpentane (**5**), 1-isopropyltetralin (**22**) from 2-chloro-2-methyl-6-phenylhexane (**6**) and 1-methyltetralin (**25**) from both 3-chloro-5-phenylpentane (**7**) and 2-chloro-5-phenylpentane (**8**). Previously, we have shown that the $AlCl_3$ catalyzed cyclization produced a mixture of 1,1-dimethylindan and isopentylbenzene from chloride (**1**) and a mixture of 1,1-dimethyltetralin and isohexylbenzene from chloride (**5**). Parallelly, it has been found in this work that the $AlCl_3$-induced cyclization of the tertiary chloride (**4**) gave a mixture

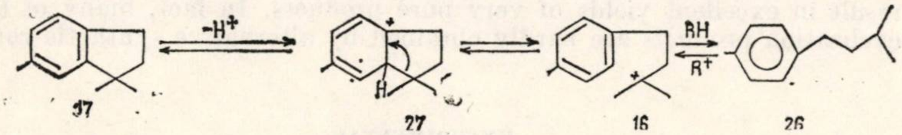
26

The production of the latter compound in the presence of the strong catalyst $AlCl_3$, can reasonably be rationalized in terms of a secondary dealkylation reaction which can be visualized as shown in equation (J).

(J)



An experimental support for the equation (J) was found in the fact that the treatment of the trimethylindan (**17**) with $AlCl_3$ under conditions similar to those used in the cyclialkylation reaction resulted in the production of the ring-opening product (**26**).

Comparing the results obtained from the cyclizations of chlorides (**1**) to (**8**) in the presence of $AlCl_3/CH_3NO_2$ or $FeCl_3$ catalyst with those obtained from the cyclization of the same chlorides in the presence of $AlCl_3$ catalyst or of the corresponding alcohols [10,11,12] in the presence of H_2SO_4 or H_3PO_4 catalyst, one can make the following observations :

1 — In cyclizing the chlorides, the use of the mild catalysts, $AlCl_3/CH_3NO_2$ and $FeCl_3$ instead of the strong catalyst $AlCl_3$ successfully inhibits undesirable secondary carbonium ion processes such as those outlined in equation (J) and whose occurrence leads to the production of isopentylbenzene from chloride (**1**), of *p*-isopentyltoluene from chloride (**4**) and of isohexylbenzene from chloride (**5**).

2 — Carbonium ion rearrangements occurring prior to the cyclization step cannot be avoided under any of the applied conditions. Thus, starting with either the chlorides or the corresponding alcohols and using either a strong or a mild catalyst, rearrangements such as the secondary-to-tertiary carbonium ion rearrangement (20)→(21) of equation (F) and the secondary-to-secondary carbonium ion rearrangement (23)→(24) of equation (G) do always occur. The deriving force for most of these rearrangements lies in the known [1,10,12] fact that a six-membered ring formation is favoured over either a five- or a seven-membered ring formation.

3 — Usually, better yields of the cyclization products are obtained from the $AlCl_3/CH_3NO_2$- or $FeCl_3$-catalyzed cyclidehydrohalogenations of the chlorides than from the H_2SO_4 or H_3PO_4 catalyzed cyclidehydrations of the corresponding alcohols, especially in systems involving tertiary ring closure to indans. For example, the yields of the cyclization products from the $AlCl_3/CH_3NO_2$-catalyzed reactions of chlorides (**1**), (**2**), (**3**), and (**4**) were respectively 79, 75, 70 and 72% while the yields from the H_2SO_4-catalyzed reactions of the corresponding alcohols [10,11] were 57, 40, 15 and 50% respectively.

[11] A. A. Khalaf and R. M. Roberts, *J. Org. Chem.*, **36**, 1040 (1971).

[12] R. O. Roblin, Jr., D. Davidson and M. T. Bogert, *J. Amer. Chem. Soc.*, **57**, 151 (1935), and references therein.

In conclusion, the results of this work demonstrated the usefullness of the mild catalysts, $AlCl_3/CH_3NO_2$ and $FeCl_3$ in effecting the cyclialkylation reactions of secondary and tertiary phenylalkyl chlorides. As these catalysts inhibit secondary carbonium ion reactions, they always result in excellent yields of very pure products. In fact, many of these cyclization products are hardly obtained by alternative synthetic routes.

EXPERIMENTAL

ANALYTICAL PROCEDURES

Vapour-phase chromatographic (v.p.c.) analyses were made using a Pye Series 104 chromatograph with a Polyethylene Glycol Adipate (PEGA) and a Methyl Silicone Gum (SE-30) columns. Infrared (i.r.) analyses were done using a Unicam SP 200 G Grating I.R. Spectrophotometer and a Beckman IR5A Spectrophotometer. Nuclear Magnetic Resonance (n.m.r.) analyses were carried out using a Varian Associates A-60 spectrometer with carbon tetrachloride as solvent and TMS as internal standard. Microanalyses were performed by the Microanalytical unit of the Chemistry Department of Assiut University, Assiut, Egypt.

SYNTHESIS OF REQUIRED MATERIALS

I. *Synthesis of Starting Chlorides*

A. *Tertiary Chlorides.* The intermediate carbinols, 2-hydroxy-2-methyl-4-phenylbutane, 2-hydroxy-2-methyl-4-(*o*-tolyl)butane, 2-hydroxy-2-methyl-4-(*m*-tolyl)butane, 2-hydroxy-2-methyl-4-(*p*-tolyl)butane, 2-hydroxy-2-methyl-5-phenylbutane and 2-hydroxy-2-methyl-6-phenylbutane were prepared according to the methods previously described by Khalaf and Roberts [1,11] for the first five carbinols and by Roblin, Davidson and Bogert [12] for the last carbinol. These carbinols were converted to the corresponding chlorides by the action of concentrated hydrochloric acid in the presence of anhydrous calcium chloride as described below.

In a typical experiment, 0.1 mole of carbinol and 30 ml of concentrated hydrochloric acid were placed in a separatory funnel and the resulting mixture was saturated with anhydrous calcium chloride and shaken thoroughly for about 15 minutes. After shaking, the layers were allowed to separate and the upper organic layer was taken and washed first with 5% sodium bicarbonate solution and secondly with water, then dried over anhydrous calcium chloride. The dry product was distilled under reduced pressure to give the pure chloride.

Applied to 2-hydroxy-2-methyl-4-phenylbutane, the above procedure gave 2-chloro-2-methyl-4-phenylbutane (1) in 80% yield: b.p. 83–86 (2.4–2.5 mm.), lit.[1] b.p. 84–85° (2.5 mm.).

Similarly, 2-hydroxy-2-methyl-4-(*o*-tolyl)butane gave 2-chloro-2-methyl-4-(*o*-tolyl)-butane (2) in 75% yield: b.p. 83–85° (2.4 mm.).

Anal. Calcd. for $C_{12}H_{17}Cl$: Cl, 18.06. *Found*: Cl, 17.63.

2-Hydroxy-2-methyl-4-(*m*-tolyl)butane gave 2-chloro-2-methyl-4-(*m*-tolyl)butane (3) in 76% yield: b.p. 86–88° (2.6 mm.).

Anal. Calcd. for $C_{12}H_{17}Cl$: Cl, 18.06. *Found*: Cl, 18.50.

2-Hydroxy-2-methyl-4-(*p*-tolyl)butane gave 2-chloro-2-methyl-4-(*p*-tolyl)butane (**4**) in 82% yield: b.p. 82–84° (2.2–2.3 mm.). The n.m.r. spectrum of this chloride had a singlet at 6.97 ppm (four aromatic hydrogens) a low-field part of an AA′BB′ system located between 2.90 and 2.59 ppm (methylene group adjacent to the aromatic ring), a singlet at 2.27 ppm (aromatic methyl), high-field part of the AA′BB′ system located between 2.12 and 1.77 ppm (second methylene group) and a singlet at 1.55 ppm (two aliphatic methyls).

Anal. Calcd. for $C_{12}H_{17}Cl$: Cl, 18.06. *Found*: Cl, 18.06.

2-Hydroxy-2-methyl-5-phenylpentane gave 2-chloro-2-methyl-5-phenylpentane (**5**) in 79% yield: b.p. 113–115° (8.2 mm.); lit.[1] b.p. 112–113° (8 mm.).

2-Hydroxy-2-methyl-6-phenylhexane gave 2-chloro-2-methyl-6-phenylhexane (**6**) in 78% yield: b.p. 110–112° (1 mm.).

Anal. Calcd. for $C_{13}H_{19}Cl$: Cl, 16.86. *Found*: Cl, 16.60.

It is to be noted that the infrared spectra of all of the above chlorides showed no hydroxyl absorption

B. *Secondary Chlorides.* The intermediate carbinols, 3-hydro-5-phenylpentane and 2-hydroxy-5-phenylpentane were prepared essentially as described by Khalaf and Roberts[1] for the former carbinol and by Roblin, Davidson and Bogert[12] for the latter carbinol. The two carbinols were converted into the corresponding chlorides by treatment with thionyl chloride in pyridine according to the following typical procedure.

A solution of 0.05 mole of the carbinol in 0.06 of pyridine was placed in a 100-ml three-necked flask equipped with a reflux condenser, a pressure-equalizing dropping funnel, a thermometer and a stirring magnet. The flask was then surrounded by an ice bath and the stirrer was started while 0.06 mole of freshly distilled thionyl chloride was added from the dropping funnel at such a rate that the temperature of the reaction mixture did not rise above 10°. After addition was complete, the reaction mixture was stirred at room temperature for two hours and at 50° for one hour then decomposed by pouring over ice. The organic product was extracted with ether, washed repeatedly with ice-cold water then with 10% sodium bicarbonate solution and again with cold water. The washed solution was dried over anhydrous calcium chloride and distilled under reduced pressure.

Applied to 3-hydroxy-5-phenylpentane, the above procedure gave 3-chloro-5-phenylpentane: b.p. 92–94° (3.1 mm.); lit. b.p. 91° at 3.0 mm[1] and 100° at 12 mm[2].

Similarly, 2-hydroxy-5-phenylpentane gave 2-chloro-5-phenylpentane: b.p. 90–91° (3.0 mm.); lit[2]. b.p. 100° (12 mm.).

II. *Synthesis of Final Products*

The required 1,1-dimethylindan (**10**), 1,1,4-trimethylindan (**12**), 1,1,5-trimethylindan (**14**), 1,1,7-trimethylindan (**15**), 1,1,6-trimethylindan (**17**), 1,1-dimethyltetralin (**19**), 1-methyltetralin (**25**) and *p*-isopentyltoluene (**26**) were prepared as previously reported by Khalaf and Roberts.[1,11] Details concerning the preparation of compounds (**10**), (**19**) and (**25**) are given in reference [1] and those concerning the preparation of compounds (**12**), (**14**), (**15**), (**17**), and (**26**) are given in reference.[11]

The required 1-isopropyltetralin was prepared by the reaction of isopropylmagnesium bromide with 1-tetralone followed by reduction of the resulting 1-hydroxy-1-isopropyltetralin by hydrogen and palladium on carbon in glacial acetic acid containing little perchloric acid.[13] The product obtained had a b.p. of 99–100° at 0.53 mm.; lit.[12] b.p.: 247° at atmospheric pressure.

---

CYCLIALKYLATION PROCEDURES

a) *Using $AlCl_3/CH_3NO_2$ as catalyst*

To a 50-ml, two-necked, round-bottomed flask equipped with a magnetic stirrer, a pressure-equalizing dropping funnel and a reflux condenser fitted with a calcium chloride tube was placed 0.002 mole of anhydrous $AlCl_3$, 0.02 mole of nitromethane and subsequently 30 ml of solvent (CS_2 or petroleum ether, b.p. 60–80°). To this was added dropwise (over a period of 15 minutes) a solution of 0.02 of the phenylalkyl chloride in 20 ml of the same solvent. After the addition was complete, the reaction mixture was allowed to stir at room temperature for another 45 minutes, then decomposed with a 5% hydrochloric acid solution. Using a separatory funnel, the organic layer was separated, washed first with water and secondly with a 5% sodium bicarbonate solution and again with water, followed by drying over anhydrous sodium carbonate. The solvent was distilled under atmospheric pressure and the hydrocarbon residue was distilled under vacuum.

b) *Using $FeCl_3$ as catalyst*

The above procedure was again followed except that the $AlCl_3/CH_3NO_2$ catalyst was replaced by anhydrous $FeCl_3$.

c) *Using $AlCl_3$ as catalyst*

The procedure was also the same except that the catalyst was the strong $AlCl_3$ with no added nitromethane. Only chloride 4 was cyclized under such conditions.

Data concerning catalyst, solvent, yields and compositions of final products are summarized in Table 1.

TREATMENT OF 1,1,6-TRIMETHYLINDAN (17) WITH $AlCl_3$

In a 50-ml, one-necked, round-bottomed flask, equipped with a magnetic stirrer and a reflux condenser fitted with calcium chloride tube was placed 0.16 g (0.001 mole) of 1,1,6-trimethylindan, 20 ml of petroleum ether (b.p. 60–80°) and 0.014 g (0.0001 mole) of $AlCl_3$ and the mixture was stirred at room temperature for one hour. The mixture was decomposed and the organic layer was separated, washed and dried in the usual manner, then analyzed by vapour-phase chromatography to show that the product was a mixture of 1,1,6-trimethylindan (28%) and *p*-isopentyltoluene (72%).

IDENTIFICATION OF THE REACTION PRODUCTS

The products obtained from the above reactions were identified by comparison of their physical properties, their spectroscopic data and their vapour-phase chromatography retention times with those of the hydrocarbons prepared by unequivocal procedures.

Revue Roumaine de Chimie, 18, 2, 305–317 (1973)

ON THE REACTIVITY OF N-VINYLCAPROLACTAM IN RADICALIC POLYMERIZATION

N. COBIANU*, C. BOGHINĂ*, B. MĂRCULESCU* and I. AMĂLINEI**

* Laboratory of Macromolecular Chemistry,
Polytechnic Institute, Bucharest, Romania
** Research Department of UFS Săvineşti,
Romania

Received August 2, 1972

The copolymerization of acrylonitrile (I) with N-vinylcaprolactam (II) in solution in the temperature range of 55–70° was studied. The reactivity ratios, r_{ij}, of this pair of monomers were determined the following values being obtained :

$$r_1^{55°} = 0.29 \qquad r_1^{65°} = 0.30 \qquad r_1^{70°} = 0.27$$

$$r_2^{55°} = 0.18 \qquad r_2^{65°} = 0.15 \qquad r_2^{70°} = 0.09$$

For the determination of the Q_2 and e_2 constants for N-vinylcaprolactam (NVC) the copolymerization processes in the styrene (ST) – NVC and methyl methacrylate (MMA) – NVC systems at 70° were also studied. The values of the reactivity ratios are :

$$\text{ST} - \text{NVC}: \qquad r_1 = 19.1 \qquad r_2 = 0.027$$

$$\text{MMA} - \text{NVC}: \qquad r_1 = 5.3 \qquad r_2 = 0.05$$

The average values of the Q and e parameters are the following :

$$Q_2 = 0.116 \qquad e_2 = -1.1$$

1. INTRODUCTION

The study of the synthesis and polymerization of N-vinylcaprolactam (NVC) has been promoted by the physico-chemical properties of polyvinylpyrrolidone, a product which has been obtained in 1940–1950.

Although, from its obtaining,[1-3] many years have passed, data regarding the polymerization of NVC[3-6] and its radicalic copolymerization[7-11] are still scarce. Up to now, only the reactivity ratios for the binary copolymerization of NVC with phenyl vinyl ether,[9] buthyl methacrylate[10] and vinyl acetate (AV)[11] have been determined. The patent literature is richer and reveals many areas of utilization of such polymers.

In order to obtain more accurate information regarding the reactivity of NVC, the study of the binary copolymerization with acrylonitrile (AN), styrene (ST) and methyl methacrylate (MMA) was carried out.

2. EXPERIMENTAL

a. MATERIALS

NVC was obtained according to the method of literature. The product, purified and encapsulated under argon, was redistilled under vacuum before being used. The fraction used in the experiments had a refractive index, $n_D^{20} = 1.5135$.

AN, ST and MMA were purified according to the usual methods. The commercial α, α'-azobisisobutyronitrile (AIBN) as radical initiator was twice recrystallized from ethanol ($F_p = 102.5^\circ$).

The N,N-dimethyl formamide (DMF) was for three hours refluxed under vacuum on calcium hydride followed by double distillation ($n_D^{25} = 1.4268$).

The dioxan as pure solvent ($n_D^{20} = 1.4224$) was obtained by refluxing it on metallic sodium and then it was rectified using a column with twenty theoretical plates.

b. POLYMERIZATION PROCEDURE

Copolymerization reactions were carried out in glass ampoules with two arms[12]; before filling with monomer and initiator solutions, they were dried under vacuum and then filled with argon.

After filling, one of the arms was closed, and the ampoules were conditioned by three cycles of freezing at $-100°$, air-removal at 10^{-2} mm, filling with purified argon, and warming at 30°. Finally, the ampoules brought at normal pressure with argon were closed, and the solutions at the reaction temperature were rapidly mixed. After a sufficient reaction time as to obtain a small conversion, the copolymerization reaction is stopped by abrupt freezing near the congelation temperature. The copolymers with ST and MMA were isolated from the solution by precipitating them with petroleum ether. The precipitation of the copolymers with AN was carried out with methyl alcohol for the feed containing at least 50% mole AN and for the other situations with ethyl ether.

c. VISCOSITY MEASUREMENT

Intrinsic viscosities of copolymers were calculated using the data obtained with diluted solutions (copolymer concentration less than 0.2 g/dl) with Ubbelohde viscosimeter. The viscosity was measured in DMF for the copolymers with AN and in toluene for the other ones. The intrinsic viscosity was calculated using the following relationship[13]

$$|\eta| = \eta_{sp}/c\,(1+0.333\,\eta_{sp})$$

d. ANALYSES OF THE COPOLYMERS

The composition of the copolymers was determined according to Dumas classical micromethod. Due to the infusibility of the copolymers with high content in AN, on the one hand, and to the wetability of the copolymers with high content in NVC, on the other hand, the samples were broken up (the particle size less than 0.4 mm), dried up under high vacuum and stored under anhydrous conditions before analysis.

3. RESULTS AND DISCUSSION

3.1. KINETIC ASPECTS OF THESE BINARY COPOLYMERIZATIONS

The copolymerization of NVC with AN in homogeneous solution was carried out at different initial compositions of the feed and at three temperatures 55, 65 and 70°. Some kinetic data regarding the dependence of the initial copolymerization rate on feed composition are given in table 1. Figure 1 sums up the influence of the factors discussed above.

It is found out that the total rate of copolymerization reaches a maximum a little far from that corresponding to the equimolecular feed. Table 2 gives the results obtained for the copolymerization of ST with NVC at 70° and at a concentration of the initiator of $1.73 \cdot 10^{-3}$ mole/l.

---

[13] O. F. Solomon and B. Gottesman, *Makromol. Chem.*, **104**, 177 (1967).

Although the copolymerization reaction takes place in bulk (more than 90% of the reaction volume is taken by the monomers, the remaining being DMF), the rate of the process is much smaller than in the previous case. Figure 2 presents the dependence of the reduced copolymerization rate on the initial feed composition. It can be seen that the

** From Fig. 5

copolymerization rate increases proportionally to the ST molar fraction in feed. In this case, NVC acts as a retarder of the polymerization process.

As regards the binary system α-methylstyrene — NVC, the experiments carried out under favourable conditions (bulk polymerization, reaction time : 35 h for 70° and 100 h for 55°) for the obtaining of the products with a relatively high molecular weight, have showed that no proper copolymerization process takes place but probably one of oligomerization type. The reaction products are not precipitable in the nonsolvents of both homopolymers.

For the binary system MMA—NVC the total copolymerization rate increases monotonously with the comonomer molar fraction, tending quasi-exponentially to the total rate of the homopolymerization reaction of MMA under the same conditions. The results are presented in figure 3 and table 3.

3.2. CALCULATION OF THE REACTIVITY RATIOS

3.2.1. The AN—NVC system. The literature [8,14] does not mention the data which can be used to calculate the reactivity ratios for this

pair of monomers. Data regarding the composition of the obtained copolymers, for different initial feed, are given in tables 1 and 4.

The monomer/copolymer composition curve for the AN–NVC system is presented in figure 4.

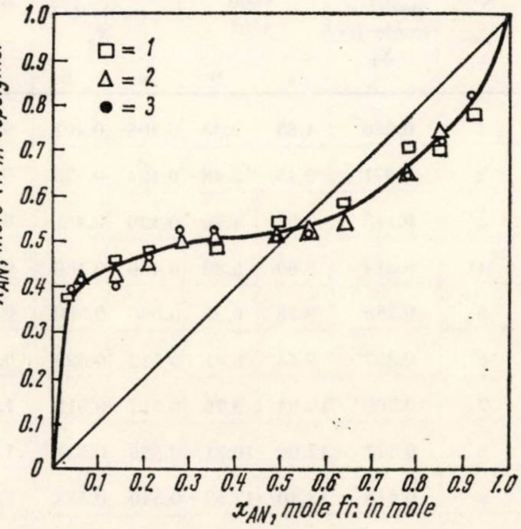

Fig. 4. — Monomer/copolymer composition curve for radical copolymerization of the AN–NVC system.

1, 55°; *2*, 65°; *3*, 70°

One observes that these three copolymerization processes at temperatures between 55° and 70°, led approximatively to the same monomer/copolymer composition curve, which shows an important tendency for the alternation of the mers. On the base of $Q_2 = 0.081$ and $e_2 = -1.55$ constants given by Sidelkowskaia *et al.*,[9] a more pronounced alternation had to be anticipated. A least square method was used for calculation of the reactivity ratios for this system.[15]

For these three temperatures, the reactivity ratios have the following values :

— temperature 55° $n = 8$ (n — the number of feeds for which the copolymerizations were done)

$$r_1 = 0.29 ; \quad r_2 = 0.18$$

— temperature 65° $n = 11$

$$r_1 = 0.30 ; \quad r_2 = 0.15$$

— temperature 70° $n = 11$

$$r_1 = 0.27 \quad r_2 = 0.09.$$

a: 65°C, b: 70°C.								Σ	5.9477

It can be seen that the reactivity ratio r_1 remains practically unchanged, while the reactivity ratio r_2 having smaller values, decreases approximately twice for an increase of temperature from 55° to 70°.

3.2.2. The ST−NVC system. As in the previous case, the copolymerization with ST is less described in literature. [7] The experimental study of the reactivity of NVC, in this binary system, offers new data for a deeper analysis. The experimental results regarding the analysis of the copolymers obtained from processes with various initial compositions of the feed are shown in table 2. Figure 5 presents the monomer/copolymer composition curve for the copolymerization of the ST with NVC.

One may observe that during copolymerization the feed becomes continuously richer in NVC.

The reactivity ratios for this system were calculated using a least square method and Fineman-Ross's method. [16] Using the least square method, for $n = 4$ (the other feeds with $x_{ST} > 0.485$ led to compositions susceptible to great errors) the following values are obtained :

$$r_1 = 18.5 \quad \text{and} \quad r_2 = 0.014.$$

The data regarding the linearization of the differential equation of copolymers composition, using Fineman and Ross's method, are presented in figure 6.

As it results from figure 6, the reactivity ratios values are :

$$r_1 = 19.1 \text{ and } r_2 = 0.027.$$

The better values for these reactivity ratios seem to be those determined by Fineman and Ross's method, taking into account the reduced number of experiments considered in the least square calculation.

Making a parallel with the binary system ST$-$Vinyl acetate (AV) for which $r_1 = 55$ and $r_2 = 0.01$, [17] one may observe that the radicalic reactivity of NVC is greater than that of AV.

3.2.3. The MMA$-$NVC system. Taking into account the fact that the constants Q_1 and e_1 of the two reference monomers from the binary system were presented above, the tentative to a better approximation of the constants Q_2 and e_2 for NVC imposed an analysis of a system with a comonomer with a polarity between that of ST and that of AN. MMA was chosen. As for the ST—NVC system, the reactivity ratios were determined by means of those two methods of linearization presented above.

---

[17] F. R. Mayo, C. Walling, F. M. Lewis and W. F. Hulse, *J. Amer. Chem. Soc.*, **70**, 1523 (1942).

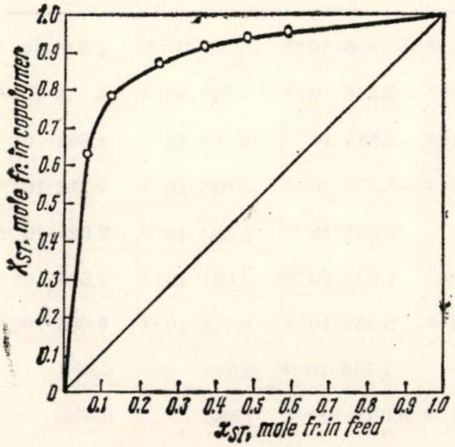

Fig. 5. — Monomer/copolymer composition curve for radical copolymerization at 70° of the ST—NVC system.

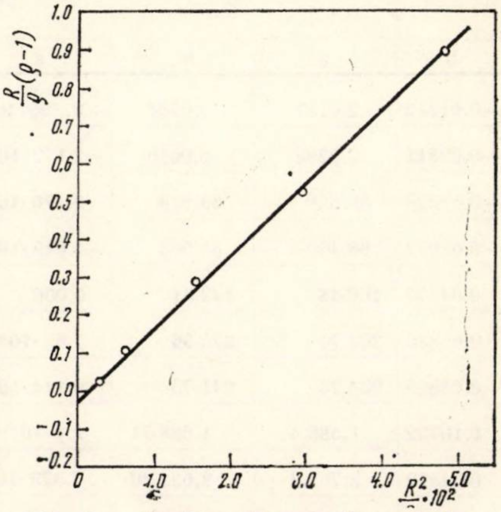

Fig. 6. — Graphic determination of the ST—NVC system constants after Fineman-Ross.

Using the least square method, for $n = 6$, the following values resulted :

$$r_1 = 5.3 \text{ and } r_2 = 0.05$$

and by means of Fineman-Ross's method (figure 7) the following values were obtained :

$$r_1 = 5.0 \text{ and } r_2 = 0.03.$$

There is a good concordance between the values obtained by these two methods.

The monomer/copolymer composition curve of the MMA—NVC system which is given in figure 8, is intermediate as related to those regarding the binary copolymerization of NVC with AN and ST but closer to that of ST.

Table 5 presents the reactivity ratios r_{ij} at 70° for the systems which were studied.

One may observe that the product $r_i\, r_j$ has the smallest value for the AN—NVC system and the highest one for the ST—NVC system, when the reactivity ratios for the second system are determined using the Fineman-Ross's method. This fact seems to be a supplemental argument for a more accurate determination of the reactivity ratios r_{ST} and r_{NVC} by means of this method.

The binary copolymerization systems of the NVC contain partners with a very different polarity (strong and weak electron accepting monomers), which in the propagation reaction give macroradicals stabilized in a higher or smaller extent by $p - \pi$ conjugation. All radicals of the partners are more stable (therefore, less reactive) than the NVC radical.

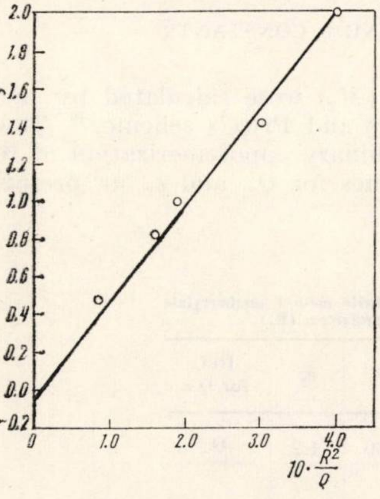

Fig. 7. — Graphic determination of the MMA — NVC system constants after Fineman-Ross.

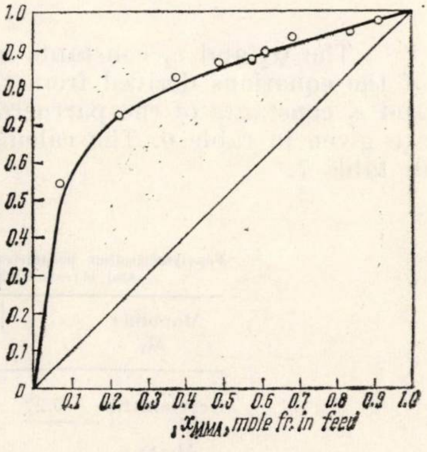

Fig. 8. — Monomer/copolymer composition curve for radical copolymerization at 70° of the MMA—NVC system.

In all these systems the tendency of this radical for cross propagation, is evidenced. Since also $r_{AN} < 1$, one believes that the propagation reactions in this system are dominated by polarity. The reverse polarity

Table 5

Values of the copolymerization constants for the monomer pairs styrene-vinyl caprolactam; methyl methacrylate-vinyl caprolactam; acrylonitrile-vinyl caprolactam

M_1	r_1		r_2		$r_1 . r_2$	
	Least-squares method	Fineman-Ross method	Least-squares method	Fineman-Ross method	Least-squares method	Fineman-Ross method
Styrene	18.5	19.1	0.014	0.027	0.259	0.515
Methyl metacrylate	5.3	5.00	0.05	0.03	0.265	0.15
Acrylonitrile	0.27	—	0.09	—	0.0246	—

of the two monomers lowers much the energy of the activated complexes of the cross addition. The probability of homopropagation of AN being much diminished, it becomes important only for feeds with a high content of this monomer.

3.3. CALCULATION OF Q AND e CONSTANTS

The Q_2 and e_2 constants for NVC (M_2) were calculated by means of the equations derived from the Alfrey and Price's scheme.[18] The Q_1 and e_1 constants of the partners of the binary copolymerization of NVC are given in table 6. The calculated values for Q_2 and e_2 ar presented in table 7.

Table 6

Copolymerization parameters foracrylonitrile methyl methacrylate and styrene: with N-vinyl caprolactam (M_2)

Monomer M_1	r_1	r_2	Q_1	e_1	Ref. for Q,e
Acrylonitrile	0.27	0.09	0.60	1.2	19
Methyl methacrylate	5.0	0.03	0.74	0.4	19
Styrene	19.1	0.027	1.00	−0.8	18

Table 7

Q, e Parameters for N-vinyl caprolactam (M_2)

N-vinyl caprolactam M_2	M_1			Average parameters
	Acrylonitrile	Methyl methacrylate	Styrene	
e_2	−0.73	−0.96	−1.61	−1.1
Q_2	0.210	0.082	0.056	0.116

The average constant $e_2 = -1.1$ demonstrates a donor effect of the substituent of this vinylic monomer lower than that supposed from the copolymerization with phenyl ether,[9] with AV[11] or that resulted from the copolymerization with ST, in the last case the decisive factor of the process being that of the conjugation.

The value $e_2 = -1.1$ anticipates a relative weak tendency of NVC for a cationic polymerization. This fact is in good agreement with the experimental data obtained for the cationic polymerization of N-vinylpyrrolidone with boron trifluoride[20] and with the value obtained by

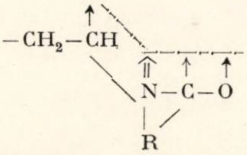
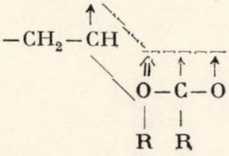
[20] C. E. Schildknecht, A. O. Zoss and F. Grosser, *Ind. Eng. Chem.*, **41**, 2891 (1949).

Alfrey [21] for N-vinylpyrrolidone. Comparing the average values of Q and e of NVC, with those of AV ($Q_{AV} = 0.02$ and $e_{AV} = 0.5$ [22]) one may evidence the following:

— The radicalic reactivity of NVC is higher than that of AV, while the reactivity of the radicals is in a reverse ratio. From this point of view it is evident that the stabilization of the radical:



is firmer than that of the radical:



which one explains by the lower potential energy of the conjugated lactamic system than that of the acetoxy system.

— The energy difference between the two systems consists in fact in the stronger electronegative character of the esteric oxygen, as compared to that of the amidic nitrogen.

— As regards the values e of the two monomers, in the case of NVC the donor effect in front of the acceptor partners is more pronounced, which can be explained by the difference in the electronegativity showed above.

As it has been experimentally observed in the copolymerization with strong electron accepting monomers (AN) there is a total copolymerization rate higher than in the copolymerization processes with weaker electron accepting monomers (MMA) and all the more so with amphoter partners (ST).

In the copolymerization with monomers which have strong electrophilic substituents one may expect the copolymerization rate to reach a maximum for the equimolecular feed.

STUDIES ON THE ELECTROANALYTICAL BEHAVIOUR OF MEMBRANE-ELECTRODES UNDER CURRENT. I

CURRENT-MEMBRANE POTENTIAL CURVES FOR THE PARCHMENT MEMBRANE-ELECTRODE IMPREGNATED WITH $BaSO_4$

CANDIN LITEANU and IONEL CĂTĂLIN POPESCU

Chair of Analytical Chemistry, "Babeş-Bolyai", University,
Cluj, Romania

Received September 11, 1972

Some new current-membrane potential measurements for $BaSO_4$-parchment membrane-electrode are exposed. The measurements ranged in the rectification domain. A Tafel diagram is suggested for the interpretation of the results. A kinetic hypothesis is also proposed for understanding the behaviour of $BaSO_4$-parchment membrane-electrode in dynamic state conditions.

The great majority of studies and uses referring to the membrane-adjacent solution electrochemical system, is meant to capitalize on the behaviour of this system when the net current passing through it is extremely feeble ($10^{-12}-10^{-14}$ A). This is especially the case for working the ion selective membrane-electrodes.

There exist nevertheless some research fields dealing with phenomena connected to the behaviour of permselective membranes through which a relative higher electric current passes, as for instance : electrodialysis,[1] rectifying of alternating electric current,[2-5] conductometric titration with indicating resistance[6-8] and a variant of coulometric generation.[9] The method of passing a current through the membranes has also lead to interesting results in the study of working mechanism of membranes,[10] and of the transitory response of glass electrodes,[11-14] as well as in potentiometric titration.[15-16]

The present note gives some new results on the electrochemical behaviour of the membrane-electrode of parchment impregnated with $BaSO_4$, obtained by interpreting the current-membrane potential curves plotted in a dynamic state. The investigated domain corresponds to the rectifying region ($0.65\ \text{V} < E_m < 0.90\ \text{V}$) signalled in similar studies on this type of electrode.[17,18]

EXPERIMENTAL

The membrane-electrode of pergament impregnated with $BaSO_4$ was used in the form described by Liteanu and Mioşcu.[19] Some constructive changes were nevertheless necessary: a platinated Pt electrode (plate 1 cm × 1 cm) was introduced into the membrane-vase. Another platinated Pt electrode of identical form and dimensions was set outside. This couple of electrodes, symmetrically set on each side of the membrane, has served to apply the external polarization tension.

During the whole experiments $Ba(OH)_2\ 5 \times 10^{-2}$ N was used as internal solution and $H_2SO_4\ 5 \times 10^{-2}$ N as external solution. The external solution was stirred magnetically.

The polarization tension was picked up from the cylinder of a polarograph (Radelkis OH 102) turning with a suitable and known speed. The intensity of the electric current passing through the membrane is directly registered by the polarograph.

The potential of the membrane-electrode was estimated by measuring at 10 seconds interval with an electronic potentiometer (Radiometer TTT1) the emf of the electrochemical chain:

$$(+)\ \text{ESC}\,\big|\,\text{Ba(OH)}_2\ 5\times10^{-2}\ \text{N}\,\big|\,\text{membrane}\,\big|\,\text{H}_2\text{SO}_4\ 5\times10^{-2}\,\big|\,\text{ESC}\ (-) \qquad (1)$$

The block-draft of the working device is given in figure 1.

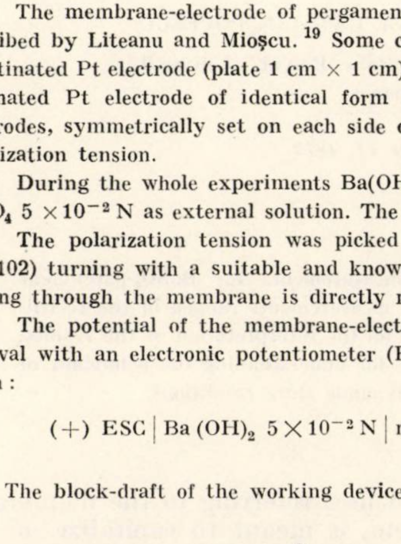

Fig. 1. — The schematic diagram of the working assembly: *1*, polarograph; *2*, working cell; *3*, $BaSO_4$-parchment membrane; *4*, Pt-platined electrodes; *5*, SCE; *6*, potentiometer.

EXPERIMENTAL RESULTS

Considering the parchment-membrane electrode impregnated with $BaSO_4$, separating the $Ba(OH)_2$ from the H_2SO_4, analogous to a $n - p$ junction,[20,21] one has called inverse polarization the application of a tension between the Pt electrodes thus directed that the electrode sunk in the hydroxide solution positivates versus the one sunk in the acid solution. The inverse situation was called direct polarization.

Inverse polarization. Proceeding to the dynamic raising of the current-membrane potential curve, one has applied an external polarization tension varying linearly with the time between the electrodes, according to the relationship

$$E = k \cdot t \tag{2}$$

where $k = 8.33 . 10^{-3}$ V/sec.

The results of the $I - t$ or $E_m^{'} - t$ recordings are reproducible. Two typical curves are presented in figure 2.

To clear up the reasons for the apparition of the null ordinate domain on the $I - t$ curve (fig. 2, curve 2), one has proceeded to the shifting of the zero point of the recorder, thus putting into evidence the passing of a current having an inverse direction to the polarization one. Figure 3 gives two $I - t$ curves obtained in the two above mentioned ways.

By correlating $I - t$ data with $E_m - t$ data, the curve $I - E_m$ corresponding to the inverse polarization represented on figure 4 was obtained.

The curve $I - E_m$ can surprisingly be partially linearized by the Tafel type diagrams. Thus, making use of the data in figure 4 and considering as overvoltage of the membrane electrode (η) the positive difference between the value of the potential of the inverse polarized electrode and the value of the potential of the resting electrode, one has noticed that :

— for values of $\eta < 0.1$ V, that curve $I - E_m$ admits equation

$$\eta = K \cdot I^* \tag{3}$$

where $I^* = I - I_0$, and I_0 is the intensity of the current passing through the membrane when $\eta = 0$. The experimental data according to the equation (3) are rendered in figure 5.

— for values of $\eta > 0.1$ V, the curve $I - E_m^{'}$ takes a linear form according to the equation (4)

[20] H. Reiss, *J. Chem. Phys.*, **21**, 1209 (1953).

[21] C. S. Fuller, *Rec. Chem. Progr.*, **17**, 75 (1956).

$$\eta = A + B.\lg I^* \qquad (4)$$

where A and B are two constants, and I^*, is as above defined. A corresponding representation appears in figure 6.

From $I - t$ data (fig. 2, curve 2), correlated to the values of the external polarization tension, according to the equation (2), one has graphically computed (method of tangents) the evolution of the cell resistance in time ($R - t$). Then, correlating the $E_m - t$ data (fig. 2, curve 1) with the $R - t$ data obtained above, one has plotted curve $R - E_m$ (fig. 7). One obtains a curve with a marked maximum corresponding to the value of the equilibrium potential of the membrane-electrode.

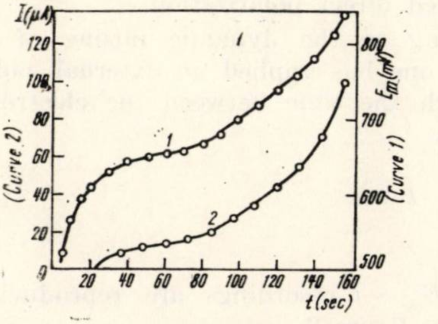

Fig. 2. – The $E_m - t$ (*1*) and $I - t$ (*2*) curves for reverse polarization.

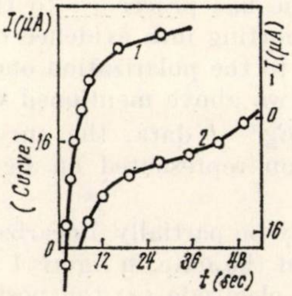

Fig. 3. – The $I - t$ curves with (*1*) and without (*2*) polarograph nul point removal.

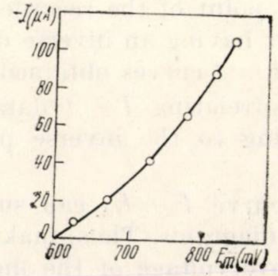

Fig. 4. – The $I - E_m$ curve for reverse polarization.

Direct polarization. Following the same method as in the case of inverse polarization, one has plotted the curve $I - t$ and $E_m - t$. By correlating these data one has obtained the curve $I - E_m$ for direct polarization. This was represented together with the curve $I - E_m$ of inverse polarization, giving the global $I - E_m$ curve, rendered by figure 8.

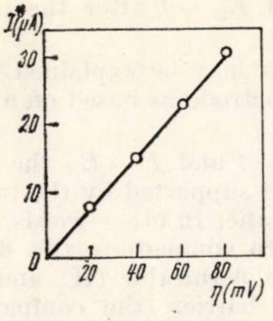

Fig. 5. — The linearization of $I^* - E_m$ curve, for $\eta < 0.1$ V.

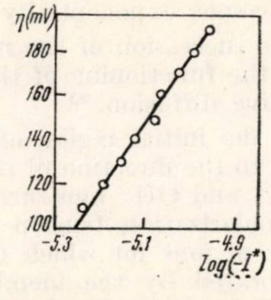

Fig. 6. — The linearization of $I^* - E_m$ curve, for $\eta > 0.1$ V.

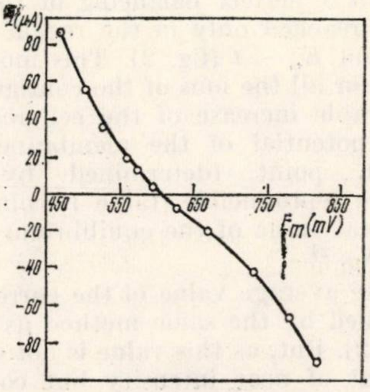

Fig. 8. — The whole $I - E_m$ curve for $BaSO_4$-parchment membrane-electrode.

$I > 0$ direct polarization; $I < 0$ reverse polarization.

DISCUSSIONS

By analysing the curves $I - t$, $E_m - t$ and $R - E_m$ corresponding to inverse polarization, one may note:

1. In the field of relatively small external polarization, a current contrary to the direction of the polarization passes through the membrane. The potential of the membrane-electrode decreases abruptly, reaching the resting value with the annulment of the current.

2. In the region in which the polarization tension nears the resting value of the membrane-electrode potential, an inflexion point appears on the curves $I - t$ and $E_m - t$, and curve $R - E_m$ simultaneously presents a maximum.

3. The shape of the curves $I - t$ and $E_m - t$ after the inflexion point becomes exponentially increasing.

The succession of the noted phenomena may be explained by considering the functioning of the membrane-electrode as based on a process of selective diffusion. [22]

In the initial region of the curves $I - t$ and $I - E_m$ the current contrary to the direction of the polarization is supported by the transport of the H^+ and OH^- ions through the membrane. In other words, as long as the polarization tension is insufficient to compensate the diffusion tendency of ions for which the membrane is permeable (H^+ and OH^-), unequilibrated by the membrane potential barrier (the compartments are shorted outside by connection to the tension source), the ions will penetrate undisturbed the membrane. The very moment the outer polarization tension equilibrates this tendency, the potential of the membrane returns to the resting value.

But a perfect balancing of the diffusion tendency of the H^+ and OH^- is reached only in the region of the inflexion point on the curves $I - t$ and $E_m - t$ (fig. 2). This moment the membrane becomes impermeable for all the ions of the contiguous solutions, a fact reflected by the considerable increase of the cell resistance (Fig. 7). The average value of the potential of the membrane-electrode (644.8 ± 5.1 mV) at the inflexion point (determined by the method Hahn-Weiler [23]) is therefore reproducible (table 1, column 3) and is in agreement with the theoretical value of the equilibrium potential for this couple of solutions (645 mV). [24]

The average value of the current intensity, at the inflexion point — determined by the same method as above is also reproducible (table 1, column 2). But, as this value is not equal to zero, this means that at rest, a current of near intensity but contrary direction passes through the membrane. This is a discharge current, made of H^+ and OH^- ions. It is probably caused by the unsuited porosity of the support. The immediate result is the establishment for the resting potential of a value inferior to that of the equilibrium potential, and a more remote result is the desactivation of the membrane-electrode.

The continuous increase of the membrane-electrode potential appears after the installation of the concentration polarization. The passing of the current is based either on the penetration of the membrane by the Ba^{2+} and SO_4^{2-} ions, or, less likely, on the electrolysis of water in the membrane.[17,18]

Regarding the Tafel-type interpretation of curve $I - E_m$, we must recall that the theory of these diagrams can also be adopted by the phenomena studied by us. For the time being, based on the analogy between the $BaSO_4$-parchment membrane system and a $n - p$ junction, [18] one can explain the use of Tafel type diagrams to interpret the curve $I - E_m$, obtained in the case of inverse polarization.

Table 1

The current intensity (I^*) and the membrane-electrode potential (E_i) values corresponding to the inflexion points and the various I^*-E_m curves

Current number	I^* (uA)	E_i (mV)
1	8.8	644
2	7.2	642
3	10.2	646
4	9.6	641
5	12.2	646
6	11.2	644
7	9.6	643
8	14.2	655
9	12.6	654
10	7.8	633
	$\bar{I}^* = 10.2 \pm 1.0$	$\bar{E}_i = 644.8 \pm 5.1$

$k = 9$; $t = 2{,}26$; $\alpha = 0.95$.

The following equation is well known

$$i = i_s(e^{VF/RT} - 1) \tag{6}$$

where : i is the net current through the junction ; i_s is the exchange current, characteristic to the type of junction ; V is the potential difference applied to the junction ; all the other notations have the usual meaning). If we write

$$V = \eta \tag{7}$$

and

$$i = I^* \tag{8}$$

and consider that only the electric potential difference $(E - E_m)$ is the force supporting the passage of current (I^*) through the membrane we easily rediscover the empiric equations (3) and (4).

Thus, when $\eta < (RT/F)$, taking into account the relations (7) and (8) we can transform the relation (6), by series development of the exponential function, obtaining

$$I^* = i_s\eta/(RT/F) \tag{9}$$

a relationship showing a linear dependency $\eta - I^*$, appearing in figure 5.

Also, when $\eta > (RT/F)$, one can neglect the second term of the equation (6), and based on equations (7) and (8), one obtains

$$I^* = i_s\, e^{F\eta/RT} \tag{10}$$

a relationship putting into evidence a linear dependency $\eta - \lg I^*$, as in figure 6. The slope of the experimental line (237 mV) differs from its theoretical value ($2.303\ RT/F = 59$ mV, at $T = 298°$ K). In fact this discrepancy between the experimental results and the theoretical previsions is general when one makes use of the $n-p$ junction model to interpret the current-tension characteristics of the systems : bipolar membrane adjacent solutions.[2–5]

Received June 17, 1972

This paper deals with the structural investigation of the acrylonitrile — methylmethacrylate copolymers synthesized by the use of the homogeneous Ziegler-Natta type catalyst system: bis (cyclopentadienyl)-titanium dichloride-triethylaluminum.

In some previous works, [1–6] the kinetics and the mechanism of the acrylonitrile copolymerization with acrylic-, vinyl aromated- comonomers and with epichlorohydrine, using the Ziegler-Natta type soluble catalyst, constituted by bis(cyclopentadienyl)-titanium-dichloride-triethylaluminum has been investigated.

Continuing our work in this field, the following presentation will concern mainly with the results obtained as regards the structure of the acrylic copolymers prepared with the above mentioned homogeneous catalyst.

EXPERIMENTAL PART

The homopolymers and the copolymers of acrylonitrile (AN) and methylmetacrylate (MMA) were prepared using the same polymerization procedure as that previously used.[1-6]

Data on the thermal stability were obtained with the aid of a M.O.M. Derivatograph (in air).

The flash pyrolysis has been performed using 10 μg polymer samples. The pyrolysis was undertaken by the use of an induction pyrolyzer (Curie point), the degradation products being analysed by vapour-phase chromatography.

The N.M.R. spectra were recorded, by the use of a J.E.O.L. 60 MHz apparatus, at 160° (solvent $CDCl_3$, internal reference TMS).

X-ray investigations, T.U.R. M-60 apparatus, were performed using the $K\alpha$ ray of the copper.

Gravimetric average molecular weights M_w have been determined by a P.C.L. Peaker type, light scattering apparatus.

RESULTS AND DISCUSSION

The physico-mechanical properties of typical AN-MMA copolymers were checked and some examples taken from our studies will serve to illustrate their characteristics. The obtained results are summarized in Table 1.

Table 1

Physico-mechanical characteristics of the MMA-AN copolymers prepared by the $Cp_2TiCl_2-AlEt_3$ catalyst

N %	Tensile strength Kgf/cm²	tgδ %	Specific resistance Ω·cm	Resistance to sparking KV/mm
4.72	422	2	$4.50 \cdot 10^{15}$	12.0
5.10	422	1	$1.40 \cdot 10^{15}$	23.6
4.50	420	2	$1.42 \cdot 10^{14}$	26.5

It is seen from this table, that our copolymers (similarly to the technical MMA) possess very good mechanical and electrical properties. In order to bring the results in agreement with our concept of polymerization kinetics and mechanism let us focus our attention on the structural investigation of these materials. The purpose of this work is mainly to discuss some structure kinds of these polymers, i.e. solubility, crystallinity, thermal stability, structural homogeneity, sequence distribution and tacticity.

SOLUBILITY

On returning to the I.R. spectra of the AN-MMA copolymers the products appear to have a rather different character from that of free radical- or ionic polymers. The differences may arise partially from the existence of cyclized structures in polymers. In accordance with this finding, an insoluble fraction (in usual solvents, e.g., chloroform, or N,N-dimethylformamide) of these polymers has been found.

For further evaluations an average value of 10–30 per cent must be considered, for this insoluble fraction, depending on the synthesis conditions (e.g. temperature and aluminium/titanium ratio).

THERMAL STABILITY

Thermogravimetric data provide a further experimental evidence, supporting the idea that the AN-MMA copolymers prepared by the $Cp_2TiCl_2-AlEt_3$ catalyst contain some cyclized structures. The results show clearly the presence of destruction regions situated at temperatures above 400°, and furthermore, an important unpyrolysed residue content. Results are given in table 2.

Table 2

Derivatographic analysis data

Polymer	Catalyst	Residue % g	Destruction interval,°	Maximum decomposition temperature,° $T_{M_1}, T_{M_2}, T_{M_3}$	Activation energy Kcal/mole	Reaction order n

Observations : ′results obtained by crucibles ; ″by plates ; unfractionated polymer (*)

As it results from table 2, a difference concerning the composition of the calcination residue regarding fractionated or unfractionated polymer can be accounted for. Assuming that, for the first case in residuum constitution only the rests of catalyst chemically bonded participate, for the latter case it could be expected that both the chemically bonded promoters residue and the cyclised structures contribute to the formation of the unpyrolysed residuum.

The thermogravimetrical analyses of polyacrylonitrile indicates the existence of three destruction domains, as can be seen in the figure 1 (the maximum temperatures are reported in table 2).

The interpretation of the first destruction domain seems to be somewhat difficult, as it is situated more below the decomposition domain of the free radical PAN. The second interval, situated at 300°, can be assigned to the linear PAN, and the last, situated above 800°, to the cyclized PAN. We remark that polymethacrylonitrile (PMAN) characterized by the existence of two destruction domains, possesses this first domain at a higher temperature in comparison to PAN (see Fig. 2).

Fig. 2 represents the derivatograms of the PMAN synthesized by free radicalic and Ziegler type catalyst.

Making use of these data, by the aid of the Freeman-Caroll [7] method, one can calculate the activation energies for the main destruction domain (200–400°), as can be seen in Fig. 3.

The literature data, [8] show that the use of this method permits to obtain overall activation energy values, which can be used (together with the initial decomposition temperatures) for thermal stability characterization. As can be seen in table 2, the reported values differ, depending on the polymer nature. One can constate an increased thermal stability for PMAN prepared by homogeneous catalyst with respect to free radicalic polymer.

It can be observed from figure 1, that PMMA synthesized by homogeneous catalyst is characterized by an increased thermal stability and a singular decomposition domain, with respect to the other two homopolymers (which present some decomposition processes).

The thermogravimetric study of the AN-MMA copolymers synthesized by the homogeneous catalyst, gives the results compiled in figures 4 and 5.

As can be seen from the data presented in the above figures, the copolymers investigated by us, present a relatively high thermal stability with respect to PMMA. It is generally assumed that one can characterize quantitatively the thermal stability of the polymers on the basis of the activation energies and of the destruction order. These data are reported in table 2.

Furthermore, in order to evaluate quantitatively the influence of the impurities on the thermal behaviour of the polymers, some measures with purified (by successive reprecipitation) and unpurified PMMA were realized (the chloroform-ethanol system as a solvent precipitant one for

polymer purification has been used). The results are summarized in table 2. As can be seen from the data of table 2, the activation energy values differ with ±5 Kcal/mole, depending on the polymer purification degree;

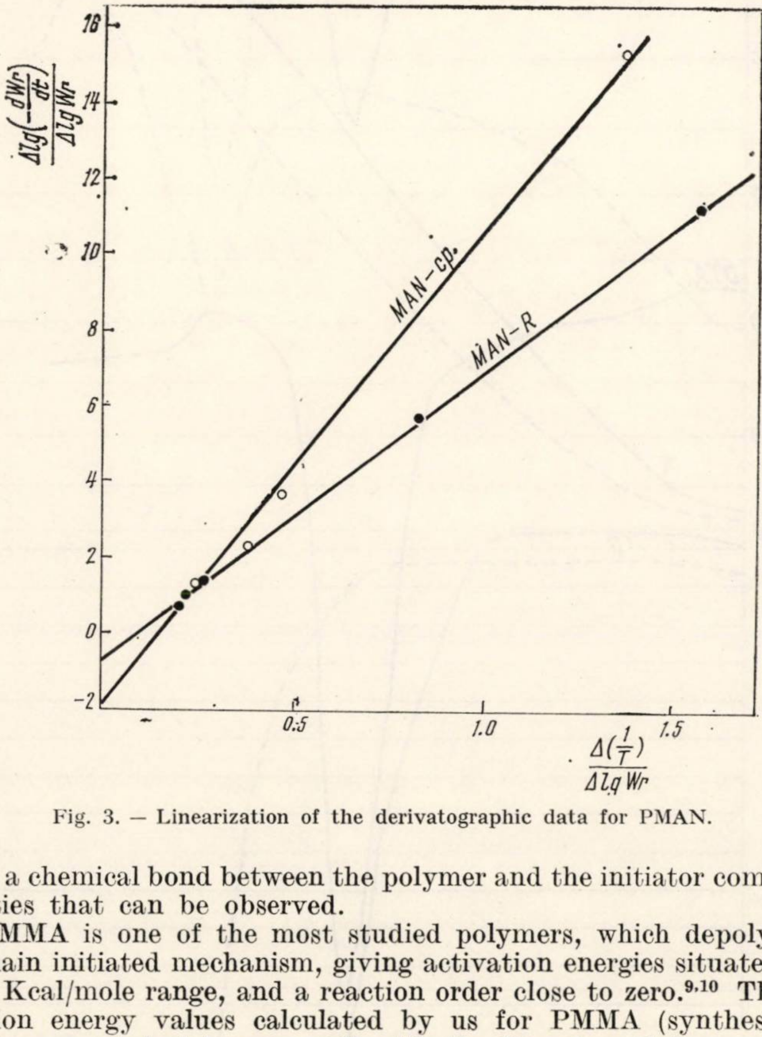

Fig. 3. — Linearization of the derivatographic data for PMAN.

there is a chemical bond between the polymer and the initiator components impurities that can be observed.

PMMA is one of the most studied polymers, which depolymerizes by a chain initiated mechanism, giving activation energies situated in the 32—42 Kcal/mole range, and a reaction order close to zero.[9,10] Thus, the activation energy values calculated by us for PMMA (synthesized by homogeneous catalysis) agree well with the literature data.

It can be observed, that the calculation errors which may derive on the one hand from the different degrees of purification of the polymers and, on the other hand, from the method itself, make the obtained "n" and "E" values to be only orientatively used.

STRUCTURAL HOMOGENEITY

Preliminary experiments taught us that the polymers have a structure composed by a soluble fraction and an insoluble one. Thus the techniques involving the assay of solution might be applied only to the soluble fraction examination.

It could be expected for the PMAN (which is soluble in usual solvents) study to give some structural data also applicable to PAN. However, it is safe to say, that the extrapolation of PMAN solubility and thermal resistance data for PAN is doubtful. One can constate, that PMAN contains reduced quantities of unpyrolised residue with respect to PAN (see table 2) and a reduced hot acetone insoluble fraction content (smaller than 10%). Therefore, the insoluble (cyclised) structure content is little and the increased „solubility index" value denotes the lack of crystallinity and stereoregularity.[11]

In addition, structural homogeneity (molecular weight and composition polydispersity) data for the soluble polymer fractions were reported.

---

[11] Yasushi Yoh, Toshio Yoshihara, Yahide Kotake, Yoshikatsu Imai and Seiki Kurihara, *J. Polymer. Sci.*, **A 1**, 605 (1967).

It is obvious that the molecular weight determined by light scattering for copolymers is an apparent value, M_{ap} depending on the solvent used.[12] It has already been demonstrated that this apparent value is given by the following expression

$$M_{ap} = M_w + 2P\left(\frac{\nu_A - \nu_B}{\nu}\right) + Q\left(\frac{\nu_A - \nu_B}{\nu}\right)^2 \tag{1}$$

where

$$P = \frac{\Sigma c_i M_i \delta x_i}{\Sigma c_i} \tag{2}$$

$$Q = \frac{\Sigma c_i M_i \delta x_i^2}{\Sigma c_i} \tag{3}$$

ν_A, ν_B and ν are the refractive index increments for the homopolyers and for the copolymer, when there are "c_i" molecules of molecular weight M_i ; $\delta x_i = x_i - x$ is the difference between the composition of the molecule "i" and the measured average composition.

Because there is only a reduced number of solvents for PAN and for copolymers with a high AN content, it is very difficult to make a correct study of these products by light scattering. Thus, there are only a few papers in this field. On the other hand, one can assume that the azeotrop copolymers are homogeneous in composition, similarly to the copolymers obtained at low conversions. Looking through the literature, we can see that the data refer to AN-MMA copolymers obtained at reduced conversions, having an assumed compositional homogeneity.[13] In order to simplify the measurements, the homopolymer treatment (in a singular solvent) is used for these copolymers.

In our case, there are new polymers with unknown compositional distribution and thus the simplified study is not applicable. Consequently, a great number of solvents have been used in order to determine M_{ap} values.

Refractive index increments for M_{ap} determination are calculated by additivity, in some cases they being practically verified. The dependence of refractive index increments of the polymer solutions as a function of the solvents refractive index, is described in figure 6.

Using the data of figure 6 for the light scattering measurements of the AN-MMA copolymers the following structural characteristics (cop. 1) were obtained :

As can be seen in Table 3, the determined parameters, i.e. the radius of giration $(\overline{R}_0^2)_{1/2}$ and the second virial coefficient (A_2) agree well with the literature data.[13]

A typical Zimm diagram for the AN-MMA copolymer is presented in figure 7.

It is known that the existence of a linear distribution of the apparent molecular weights, as a function of $\nu_A - \nu_B/\nu$, denotes the compositional homogeneity of the investigated copolymer. The graphical representation of the data of Table 3 gives a parabola, providing the compositional heterogeneity of the copolymer (see Fig. 8).

MMA-AN copolymer characteristics obtained by light scattering

MMA grav. % $\cdot 10^{-2}$	Solvent	$M_{ap}\cdot10^{-6}$	$M_w\cdot10^{-6}$	$Q\cdot10^{-6}$	$P\cdot10^{-6}$	$Q/Q_{max}\cdot$	$(\bar{h}_0^2)^{1/2}$ Å	$A_2\cdot10^3$
0.810	DMF	1.001	1.172	0.575	−0.337	0.330	831	0.428
	THF	1.039					822	0.306
	DMSO	1.200					581	0.148

$P=0.3375\cdot(-10^6)$; $Q=0.5750\cdot10^6$. The obtained experimental data show that the AN-MMA copolymer prepared by Ziegler-Natta catalysis

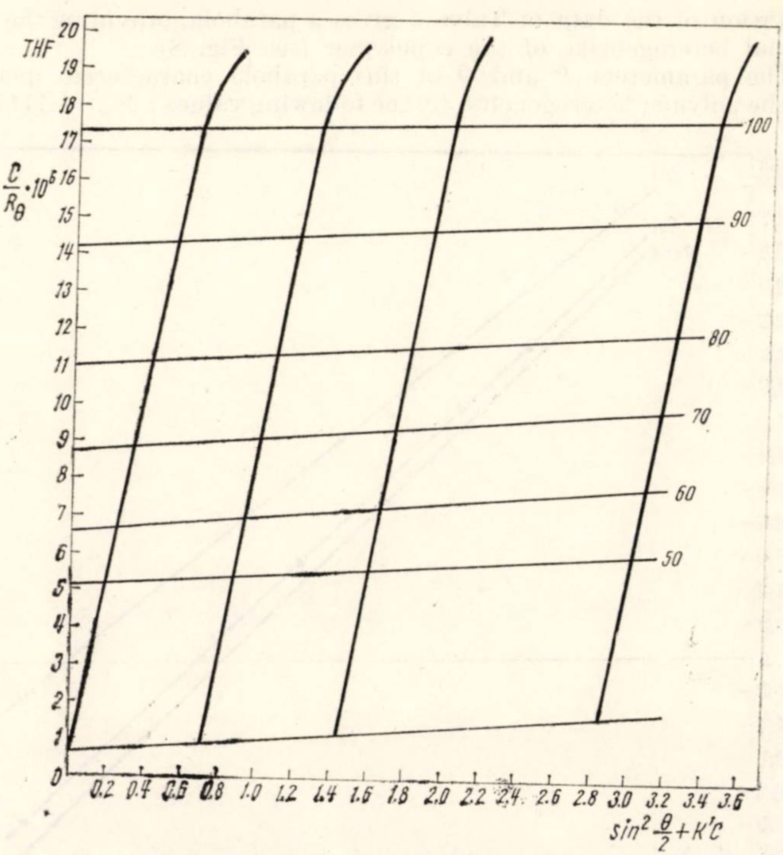

Fig. 7. — **Zimm diagram of the MMA-AN copolymer in THF.**

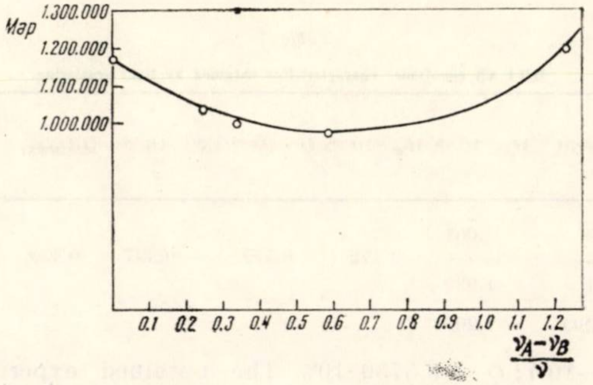

Fig. 8. — $M_{ap} = f\left(\frac{\nu_A - \nu_B}{\nu}\right)$.

is heterogeneous in composition. The comparative examination of the above summarized data, with respect to those calculated for acrylonitrile-styrene copolymers, [6] illustrates the existence of a difference, concerning the copolymer heterogeneity, between AN-MMA and AN-St copolymers. The AN-MMA copolymer has a more reduced compositional heterogeneity. This is due probably to the differences existing in the mechanism of the two discussed polymerization processes. [1-5] Thus, on the basis of our preliminary experiments, an ionic-coordination mechanism for AN-MMA copolymers and a concurrent mixed mechanism for AN-St copolymers has been assumed.

CRISTALLINITY

By X ray investigation of the PAN and PMAN soluble fractions no crystallinity has been found. On the other hand, both PMMA and the MMA-AN copolymer possess some crystallinity. The X ray diagram of a MMA-AN copolymer (cop. 1) is presented in figure 9.

As can be seen from figure 9, the MMA-AN copolymer has a per cent crystallinity index of 40. Supplemental data concerning the structural ordering of copolymers can be obtained by I.R. spectroscopic investigations using parallely and perpendicularly polarized light. The I.R. spectrum of MMA-AN copolymer recorded in polarized light is presented in Fig. 10. The total absence of dichroism is surprising (partially due probable to an insufficient orientation of the film formed by the technique of evaporation on a mercury surface and constant load straining).

SEQUENCE DISTRIBUTION

The flash pyrolysis data, concerning the MMA-AN copolymers prepared by homogeneous Ziegler-Natta catalysis demonstrate the existence of structures which are different from that of the copolymers obtained by free radicalic mechanism. One can constate that the main degradation products are AN and MMA. The dependence of the monomer yield of the destruction processus, as a function of the copolymer composition, is presented in figure 11.

The curves *a* and *b* represent the yield in AN and MMA for free radicalic copolymers pyrolysed in the same conditions, [14] and the points noted by *A* and *B* correspond to the copolymers prepared by homogeneous Ziegler-Natta catalysis. One can constate that these products have a different behaviour. The AN yield is much more and the MMA yield is also reduced with respect to the radical copolymer of the same composition.

---

[14] M. Galin, J. Guillot and A. Guyot, *J. Macromol. Sci. Chem.*, **A 4**, 19 (1970).

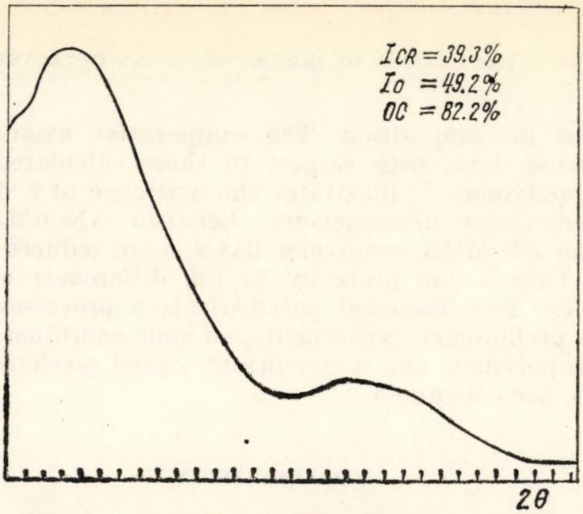

Fig. 9. — *X* ray diagram of the MMA-AN copolymer.

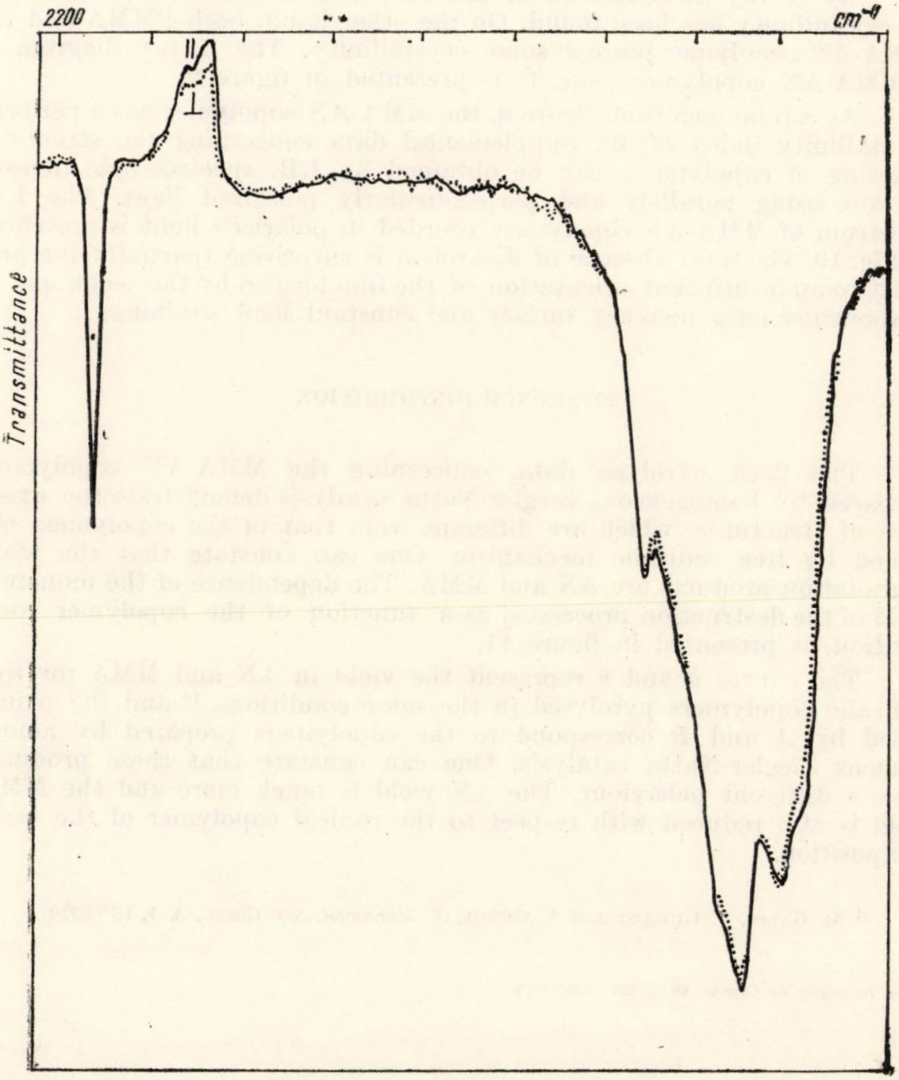

Fig. 10. — I.R. spectra of the MMA-AN copolymer in polarized light.

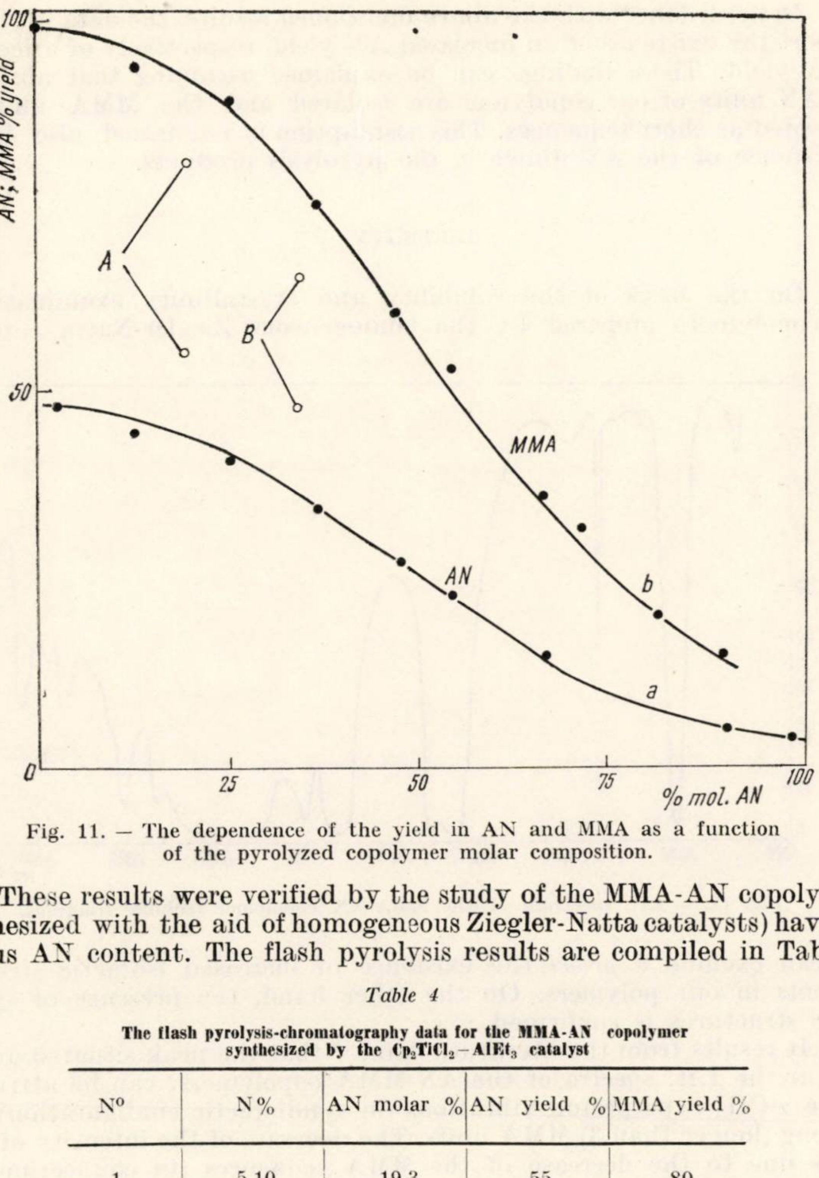

Fig. 11. — The dependence of the yield in AN and MMA as a function of the pyrolyzed copolymer molar composition.

These results were verified by the study of the MMA-AN copolymers (synthesized with the aid of homogeneous Ziegler-Natta catalysts) having a various AN content. The flash pyrolysis results are compiled in Table 4.

Table 4

The flash pyrolysis-chromatography data for the MMA-AN copolymer synthesized by the $Cp_2TiCl_2-AlEt_3$ catalyst

N°	N %	AN molar %	AN yield %	MMA yield %
1	5.10	19.3	55	80
2	6.00	22.7	67	76
3	8.15	30.8	60	55
4	8.44	31.9	57	67
5	8.61	32.5	55	68
6		25.5	42	87
7		37.0	36	74

Observation : N° 1 − 5 refer to the MMA − AN copolymer obtained by the $Cp_2TiCl_2-AlEt_3$ catalyst ; N° 6,7 refer to the free-radicalic MMA-AN copolymers with a 70 − 30%, respectively 50 − 50%, comonomer constant.

In accordance with the above mentioned results, the data of Table 4 support the existence of an increased AN yield, respectively of a decreased MMA yield. These findings can be explained assuming that almost all the AN units of our copolymer are isolated and the MMA units are imbedded as short sequences. This assumption is confirmed also by the inexistence of the AN dimer in the pyrolysis products.

TACTICITY

On the basis of the solubility and crystallinity examination of the copolymers prepared by the homogeneous Ziegler-Natta catalysis, one can exclude *a priori* the existence of increased isotactic structure contents in our polymers. On the other hand, the presence of syndiotactic structures is confirmed.

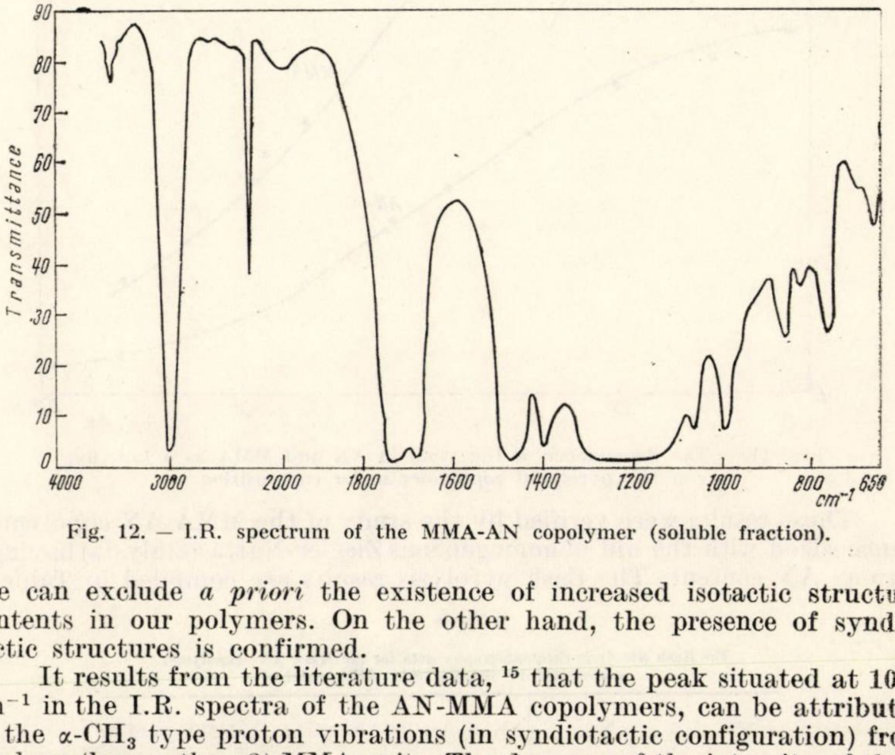

Fig. 12. — I.R. spectrum of the MMA-AN copolymer (soluble fraction).

It results from the literature data,[15] that the peak situated at 1060 cm^{-1} in the I.R. spectra of the AN-MMA copolymers, can be attributed to the α-CH_3 type proton vibrations (in syndiotactic configuration) from the long (longer than 3) MMA units. The decrease of the intensity of these bands due to the decrease of the MMA sequences (in connection with the band situated at 840 cm^{-1}, which characterizes also the MMA units, but is independent of the configuration) with the increase of the AN content in copolymer can be observed.

The I.R. spectrum of the AN-MMA copolymer is reported in Fig. 12.

As can be seen from Fig. 12, there are characteristic vibrations at 1060 cm^{-1} for the syndiotactic units in the copolymer spectrum.

---

[15] R. Schmolke, H. Herma and V. Groebe, *Faserforschung*, **16**, 598 (1965).

The literature [16] mentions the presence of a singlet at 6.42 τ (which can be attributed to the methoxy protons) and of three singlets situated at 8.65 ; 8.77 ; and 8.88 τ (assigned to the methyl protons from the isotactic, heterotactic and syndiotactic triads) in the N.M.R. spectra of the PMMA.

The N.M.R. spectra of the AN-MMA copolymer are presented in figure 13.

It is demonstrated that the presence of AN units in the AN-MMA copolymer determines some changes in the bands. [17] In the methoxy region two new bands appear. The first is situated at 6.35 τ and increases while the AN content of the copolymer increases. At a higher content than 30 AN per cent, a new peak situated at 6.32 appears. Our spectra contain all these three bands situated at 6.32 ; 6.35 and 6.42 τ (noted by A, A_1 and B).

It is known that the methoxy proton resonance in PMMA presents a tacticity independent singlet. Thus, the new bands can be attributed to the two MMA units which are situated in the neighbourhood of the AN units, and the nitrile group's paramagnetic influence gives a shift of the resonance to the reduced values of the magnetic field.

Concerning the α-methyl protons, one can observe also the presence of two new bands at 8.62 and 8.71 τ in agreement with the literature data. [17] The intensity of the band situated at 8.62 τ increases while the copolymer AN content increases as well; the intensity of the bands situated at 8.77 and 8.88 τ decreases with the increase of the AN content in the copolymer. Therefore, in spectra of our copolymer appear four bands (noted by D, E, F, G) situated at 8.66 ; 8.76 and 8.86 τ (the observed shifts in the position of the bands can be attributed to the solvent). The D and E bands are attributed to the AN units of the copolymer, and the F and G bands exist also for homopolymer).

Under the assumption that isotactic diads exist in our copolymer, two new symmetrical doublets centered about 7.6 and 8.3 τ (the methylene region in the 8.0 τ neighbourhood is not sufficiently resolved) must appear. Practically, in our spectra there are not these bands. In consequence, the D and E bands can not be attributed to the α-CH_3 protons, from the isotactic triads. On the basis of the literature data [17] the D band can be due to the isolated MMA units, situated between two AN units.

The bad resolution of the spectra does not permit the interpretation of β-CH_2 domain of the MMA and AN units and that of the CH protons from AN. Practically, the overlapping of the α-CH and of the methoxy absorption (probably, because of the weak polymer solubility) is observed.

With the following relationship, [16] the molar per cent content of MMA in copolymer, by the methoxy groups intensity (X), integral α-CH_3,

---

[16] J. Guillot, A. Guyot and Pham Quang Tho, *J. Macromol. Sci. Chem.*, **A 2**, 1303 (1968).

[17] Pham Quang Tho, J. Guillot and A. Guyot, *Compt. rend.*, **264**, 2019 (1967).

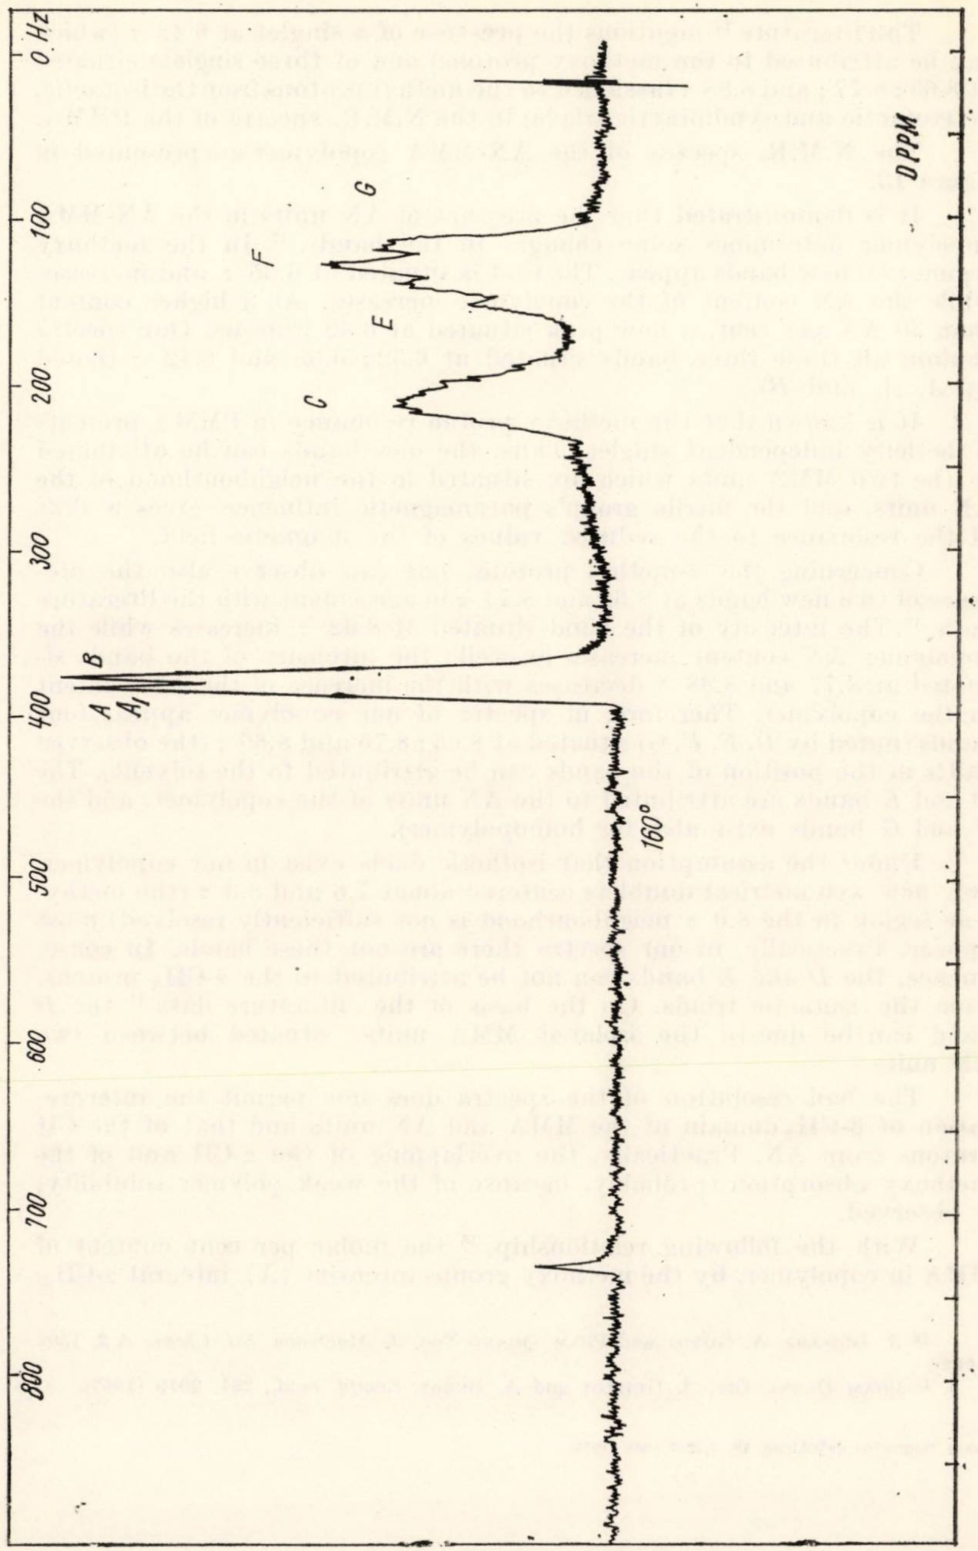

Fig. 13. — R.M.N. spectrum of the MMA-AN copolymer.

CH_2, α-CH intensity (Y) and the α-CH_3 groups intensity (Z) determination, can be calculated

$$\text{MMA }\% = \frac{X}{X + Y - 2X/3} = \frac{Y}{Z + Y - 2Z/3} \qquad (4)$$

The results of our calculus agree well with the nitrogen analysis data.

The average numerical length of the MMA sequences ($L_{MMA}n$) can be obtained from the examination of OCH_3 bands. The B band can be attributed to the internal ($n - 2$) units of the MMA sequences having n length ; the A and A_1 bands correspond to the terminal units of the sequences. The following formula holds for the ratio of intensities

$$I\,(B)/I\,(A + A_1) = (n - 2)/2 \qquad (5)$$

Then we have

$$L_{MMA}n = 2\,(1 + I\,(B)/I\,(A + A_1)) = 4.90 \qquad (6)$$

It seems therefore that the copolymer contains short sequences formed by five MMA units. These results verify the conclusions derived from our previous pyrolysis experiments.

Supplemental data, concerning the short sequences, by α-CH_3 analysis can be obtained. In PMMA these bands are triad tacticity sensible. For the copolymers, the possibility of a cotacticity [18] must be determined. As can be seen, the D band (due to the isolated units) is not sufficiently resolved. For the latter reasons, for tacticity evaluation, we discuss only the internal units of the long MMA sequences.

The data suggest, that the D band can be attributed to the MMA_1 units and the E band to the MMA_2 sequences. A very small part of this band is due to the isotactic triads from the long MMA sequences. The F band is constituted, on the one hand, from the heterotactic triads of the long MMA sequences and from the terminal units of the long MMA_x ($x > 3$) sequences, on the other hand. The G band can be attributed to the syndiotactic triads of the long MMA sequences.

In consequence, concerning the proportion of different structural units in the copolymer, the following values can be approximated : 12.5 % isolated MMA_1 units ; 12.5 % MMA_2 units ; 25 % long heterotactic sequences ; 50 % long syndiotactic units. The syndiotactic units participate with about 70 % proportion in the constitution of the long MMA sequences (which represent 75 % of the long MMA units).

A similar conclusion, concerning the presence of syndiotactic MMA units by acid hydrolysis of the polymer, was drawn. It is known that isotactic PMMA differs from that syndiotactic by the acid hydrolysis rate. [19,20] The isotactic polymer is completely hydrolysed in concentrated sulphuric acid in about one hour (at 55°). The hydrolysis rate of the syndiotactic polymer is more reduced. For a 85 per cent hydrolysis degree of the syndiotactic polymer at least 24 hours are needed. In our case, for the PMMA prepared with the homogeneous catalyst, a 13.4 per cent degree of hydrolysis (in standard conditions) after one hour was found. Consequently, the good chemical resistance supports the hypothesis of a syndiotactic configuration.

CONCLUSIONS

In order to characterize the structure (structural and compositional homogeneity, thermal stability, structural ordering, sequence distribution, tacticity, solution properties of the macromolecular chains) of MMA-AN copolymers synthesized with the homogeneous Ziegler-Natta type catalyst $Cp_2TiCl_2-AlEt_3$, several experimental techniques (i.e. derivatographic analysis, I.R., N.M.R. and X-ray spectroscopy, acid hydrolysis, pyrolysis-chromatography and light scattering) were used. The physico-mechanical properties of the polymers has also been investigated.

The solubility study, the thermal and I.R. spectroscopy showed the presence of cyclised structures and of a residual initiator content in the polymers.

The products contain a soluble fraction and an insoluble one. The soluble fractions characterized by an advanced compositional heterogeneity and a mean degree of ordering (crystallinity index of 40%), have very good physico-mechanical properties and a notable thermal stability (their heterogeneity being smaller than that of the corresponding AN-St copolymer).

For the same overall tacticity (70% of the long MMA sequences are syndiotactic) that of corresponding free-radicalic obtained copolymer, the MMA-AN copolymer prepared by the homogeneous Ziegler-Natta type catalysts, present a completely different sequence distribution, characterized by the existence of isolated AN units, separated from short MMA sequences (with an average length of 5 units).

THE FERROMAGNETIC RESONANCE OF NICKEL-CHROMIA CATALYST

IOAN INŢA and PETRE MĂRGINEANU

University of Braşov, Department of Physics, str. Karl Marx 50, Braşov, Romania
and
Institute of Atomic Physics, str. Donáth, 59 – 105, Cluj, Romania

Received February 21, 1972

By ferromagnetic resonance experiments at room temperature and in X-band (9350 MHz), two quantities have been determined : the g-spectroscopic splitting factor for $Ni-Cr_2O_3$ catalyst samples and several nickel catalyst samples on other oxide supports (MgO, Al_2O_3, SiO_2, ZnO, CeO_2) and an effective magnetization M_{ef} for $Ni-Cr_2O_3$ catalysts. The former quantity is independent of the nickel concentration in the catalyst or the type of the oxide support. At the M_{ef} variation on the nickel concentration a sudden decrease appears at the concentration of 10 – 15 % Cr. We put this variation on the account of the exchange interaction through the oxide support.

1. INTRODUCTION

In the last time, the Ferromagnetic Resonance Method (FMR) has begun to be used in the study of nickel catalysts.[1-3] Due to the obtained results the FMR investigations may offer new information on the physical properties of catalysts. For instance, by FMR studies we may obtain interesting information on the adsorption phenomenon of gases on catalyst,[2] and also some indications referring to the influence the physical properties of catalyst have upon the catalytic ones.[1]

However, one must not neglect the fact that the catalysts which contain ferromagnetic metals are generally very complex physical systems and due to this, the interpretation of FMR spectra becomes extremely difficult. For example, the nickel catalysts on oxide support, important in heterogeneous catalysis[4] are presented as polycristalline powders in which the ferromagnetic metal is dispersed as grains of different sizes within the mass of the oxide support. For such samples very large FMR adsorption lines are obtained, which emphasize the existence of many complex inner interactions (inside the ferromagnetic grain, among these grains, respectively between the grains and the oxide support).

[4] I. E. Germain, in "Catalyse heterogene", Dunod, Paris, 1959, chap. 5.

There are a few tests [3] for the establishing of the factors which influence the shape and width of the FMR lines, their dependence upon temperature, the shape and size of ferromagnetic metal grains, their concentration in catalyst and the type of the oxide support. The experimental technique used in obtaining the FMR lines in several works appeared until now, have some drawbacks, the most important being the fact that it does not offer the possibility to investigate the internal magnetic fields of the catalyst samples as powders.

In our work we try to obtain a better estimation of FMR parameters by using an experimental technique specific of the ferromagnetic metal samples having a disc shape. Researches were made about $Ni-Cr_2O_3$ catalysts, important especially for the isotopic exchange reaction of deuterium between water vapour and hydrogen.[5] We have recorded the spectroscopic splitting factor variation, g, the effective magnetization M_{ef} and the variation of the FMR line width, as function of the nickel concentration in the catalyst. In several tests, the support is made of Zn, Al, Mg, Si and Ce oxide.

2. EXPERIMENTAL

The nickel catalysts on oxide supports have been prepared by the method described in.[6] For FMR measurements samples have been prepared as thin catalyst powder layer (diameter $= 0.01-0.03$ mm), fixed on a microscope glass slide of 4×4 mm^2, by means of a polyvinilic glue. These samples have been glued with silver paste in the centre of the plane wall of a cylindrical cavity (with the mode TE_{111}), where the high frequency magnetic field has the maximum value and the electric one is null. Thus, an electric contact has been achieved between the catalyst layer and the wall of the cavity without modifying sensibly the geometry of the cavity.

The FMR measurements have been carried out with the JES$-$3B installation, using the X-band (9350 MHz), at room temperature. The derivatives of the absorption curves of FMR have registered for two orientations of the magnetic field outside the plane of the catalyst layer, namely: parallel ($H_{||}$) and perpendicular ($H_{\perp}$) to this plane.

In figure 1 are shown the FMR lines obtained for the $Ni-Cr_2O_3$ (80% Ni) and $Ni-ZnO$ (60% Ni) samples. Differences between the intensity and the position on the axis of the static field H of the FMR lines are noticed for the two orientations used. For all the investigated samples, the FMR lines corresponding to the perpendicular orientation appear at a field $H_{\perp}$ greater than $H_{||}$. This dependence of the position of the FMR maximum absorption upon the orientation of the external magnetic field against the catalyst layer plane, can be ascribed to an effective demagnetization field that appears at the perpendicular orientation ($H_{\perp}$) of the external field due to the interactions among the metallic nickel grains.

If these grains are spherical, their demagnetization field is null*) and assimilating the catalyst layer to a thin magnetic film whose effective magnetization M_{ef} is created by the interactions from among the metallic grains, the resonance conditions for the two orientations will be[7]:

---

[5] G. M. Murphy, in "Production of Heavy Water", McGraw-Hill, New York, 1951.

[6] P. Mărgineanu and A. Olariu, *J. Catalysis*, **8**, 359 (1967).

*) It becomes practically zero for nonspherical grains too, due to their random orientation.

$$\omega_{\parallel} = \gamma \, [(H_{\parallel} + 4\pi M_{ef}) \cdot H]^{\frac{1}{2}} \quad (1)$$

$$\omega_{\perp} = \gamma \, (H_{\perp} - 4\pi M_{ef}) \quad (2)$$

We notice that measuring $H_{\parallel}$, $H_{\perp}$, $\omega_{\parallel}$ and $\omega_{\perp}$, g and M_{ef} can be concomitantly determined.

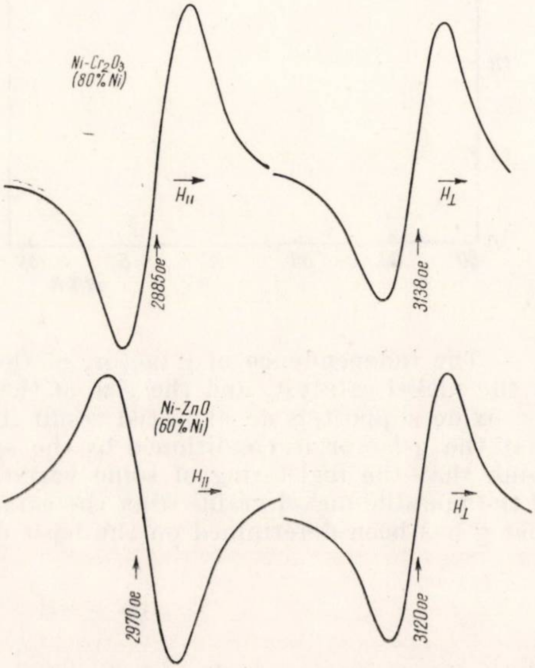

Fig. 1. — Absorption curves of FMR for $N_1-Cr_2O_3$ and $Ni-ZnO$ catalyst samples.

The static magnetic field ($H_{\parallel}$ and $H_{\perp}$) has been measured with a NMR sonde with the precision of ±8 oe and the microwave frequency with a reference cavity, the error being below 0.1 %. The width of the FMR lines has been measured by the distance between the two maxima of the derivative of the FMR absorption curve on the axis of the static field H.

3. RESULTS AND DISCUSSION

Figure 2 presents the values of the g-spectroscopic splitting factor for $Ni-Cr_2O_3$ samples, having atomic nickel concentration between 60% and 100% and for some nickel catalyst samples, on ZnO, MgO, Al_2O_3, SiO_2 and CeO_2 supports.

From figure 2 one may notice that the g-factor does not depend upon the catalyst composition or the type of its oxide support. The g-mean value being g = 2.22±0.08, it is perfectly corresponding to the value obtained for colloidal nickel ($g = 2.22 \pm 0.02$) by Bagguley.[8,9] For pure metallic nickel in bulk state $g = 2.20$ has been obtained.[10]

---

[7] I. Inţa and R. Baican, *Rev. Roumaine Phys.*, **14**, 673 (1969).

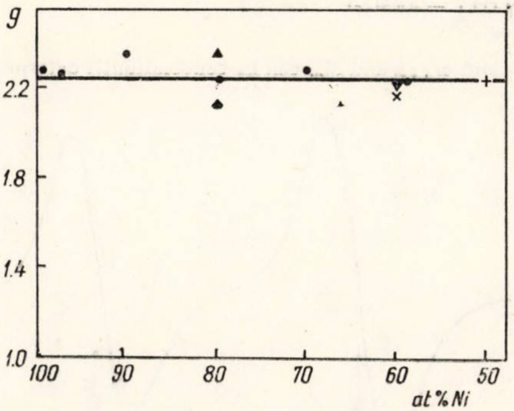

Fig. 2. — g-Factor for nickel catalyst samples on oxide supports (● : Ni — Cr_2O_3 sintered; ▲ : Ni — ZnO; ■ : Ni — MgO; ♦ : Ni — Al_2O_3; X : Ni SiO_2; + : Ni — C_eO_2)

The independence of g-factor, of the metallic nickel concentration in the nickel catalyst, and the size of the nickel grains and the type of the oxide support, is an expected result if we take into account the fact that the g-factor is conditioned by the spin-orbit interaction only. We think that the registering of some variation for g, function of the size of the metallic nickel grains from the catalyst is due not only to the fact that g has been determined on the basis of the resonance condition,

$$\omega = \gamma H \tag{3}$$

where the magnetocrystalline fields of the metallic nickel grains and of the demagnetization ones are neglected, but also to the perturbation which is determined by the catalyst probe in the resonance cavity. This perturbation (given by the eddy currents and the change in the cavity geometry) increases with the electrical conductivity of the catalyst. By using a catalyst layer in electric contact with the cavity wall, this drawback of the methods used until now [2] can be avoided.

The fact that the value of the resonance field at the perpendicular orientation ($H_{\perp}$) is greater than that corresponding to the parallel one ($H_{\parallel}$) for all the measured samples, urges us to allow the appearance of a demagnetization effective field $4 \# \pi M_{ef}$ directed perpendicularly to the plane of the catalyst layer. As it has been shown above, this field cannot be ascribed to the metallic nickel grains. Watching the M_{ef} variation upon the atomic chrome concentration of the catalyst (figure 3), we notice that a sudden decrease of it appears within the range 10—15% Cr.

[10] N. Bloembergen, *Phys. Rev.*, **78**, 572 (1950).

We should remark that such a decrease in the same concentration range can be obtained for the electric conductivity of the $Ni-Cr_2O_3$ catalyst [6], emphasizing its passing from a metallic behaviour to a semiconductor one.

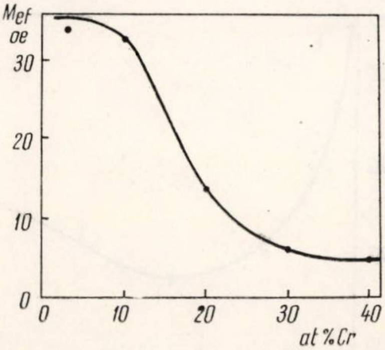

Fig. 3. — Dependence of effective magnetization of Cr — concentration in $Ni-Cr_2O_3$ catalysts.

Since the effective magnetization value M_{ef} is small in comparison with the value of the saturation catalyst,[11] we may consider that M_{ef} is created by the interactions from among the metallic nickel grains. Among these grains dipole-dipole interactions and exchange interactions by means of the oxide support can appear, given by the conductivity electrons. This type of interaction was suggested by Evdokimov. [12,13] The dipole-dipole interactions, being interactions with long range action, bring about an effective magnetic field whose intensity decreases gradually according to the "dilution" of the ferromagnetic metal in catalyst and therefore they cannot underlie the interpretation of the M_{ef} variation upon the nickel concentration in the catalyst.

The indirect exchange interactions have a small range action. They occur between the spins of some neighbouring grains, separated by an oxide layer, by means of the conductivity electrons. At a certain thickness of the oxide layer, for which the electric conductivity decreases at once [6] the number of the conductivity electrons will diminish determining a reduction of the exchange interactions through the support and therefore of the effective magnetization M_{ef}.

In figure 4 the dependence of the FMR width line ($\Delta H_{\parallel}$ and $\Delta H_{\perp}$) upon nickel concentration is graphically represented.

The presence of a minimum of this variation situated in the same concentration range (80–85% Ni) can be related to the disappearance of exchange interactions through the support. At great nickel concentrations the width of the resonance line increases markedly due to the intensifying of interactions from among the nickel crystals. The gradual

ORSZÁGOS MŰSZAKI KÖNYVTÁR DOKUMENTÁCIÓS KÖZPONT 1883

width increase of the line at concentrations less than 80% Ni, emphasizes the influence of the interactions from among the ferromagnetic metal and oxide grains (probably of ferro-antiferromagnetic type). In complex physical systems as the catalyst powders on oxide supports, the excitement of a uniform precession mode in FMR is out of question. In such substance lots of resonance modes, whose resonance frequency depends on the size and direction of the saturation magnetization vector of each grain, might probably appear. By dipole and exchange interactions their precession movements can be coupled, so that the width of the line diminishes.[14] As soon as the exchange interactions through the support disappear, the action of this effect diminishes and thus the line width will increase.

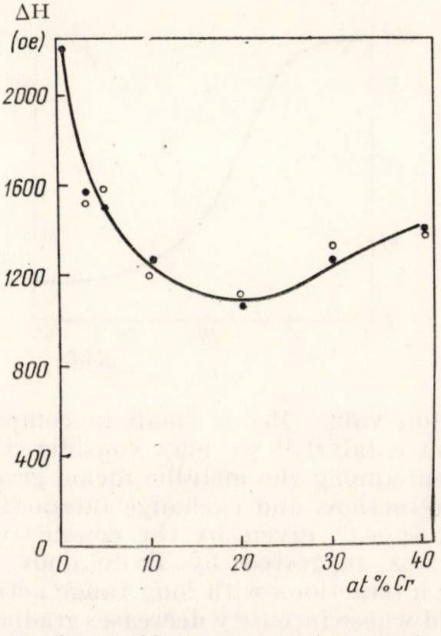

Fig. 4. — Dependence of the FMR line width on Cr-concentration in $Ni-Cr_2O_3$ catalysts (○ : $\Delta H_{\parallel}$; ● : $\Delta H_{\perp}$)

It is to be remarked that the catalytic activity of the $Ni-Cr_2O_3$ catalyst is maximum within the nickel concentration range for which the sudden variation of its electric conductivity and of the effective magnetization M_{ef} are obtained. This enables us to imagine the following mechanism which can contribute to the catalytic activity increase : for nickel concentrations, where M_{ef} decreases at once, the exchange interaction through the support, among metallic nickel grains, has maximum fluctuations and these amplify the Van der Waals forces, increasing, in this way the activity of the catalyst.

THE KINETICS OF REACTIONS BETWEEN BENZHYDRYL BROMIDE AND NORMAL ALCOHOLS

I. G. MURGULESCU and IOANA DEMETRESCU

Physical Chemistry Department, Bucharest University, Bd. Republicii 13, Romania

Received October 27, 1972

The kinetics of the reactions between benzhydryl bromide and the first four alcohols of the normal series was studied, in the temperature range 0–55°. The results were compared with those regarding the alcoholysis of the benzhydryl chloride.

INTRODUCTION

The solvolysis of benzhydryl bromide[1–4] was less studied than the solvolysis of the benzhydryl chloride. [5–12] We carried out this work in order to compare the kinetics of the alcoholysis reactions of the two halides of the same class.

EXPERIMENTAL

The benzhydryl bromide we used has been prepared in our laboratory according to known methods. [13–15] The methyl and ethyl alcohols have been anhydrized using 4 Å molecular sieves. The propyl and butyl alcohols were Merck anhydricum. The water in the alcohols has been determined by means of Karl Fisher's reagent and the following quantities were found: 0.025% in CH_3OH, 0.03% in C_2H_5OH, 0.19% in C_3H_7OH and 0.05% in C_4H_9OH.

The concentrations have been determined by a direct conductometric method, using both calibration curves given in a previous work [16] and calibrations made directly in the reaction medium. The measurements have been made by means of a CK Radiometer conductometer, with a relative errror of about 1 %. The concentrations have been checked titrimetrically with 0.032 m sodium methoxide in the presence of phenolphthalein.

RESULTS

The rate of the reaction

$$(C_6H_5)_2CHBr + ROH \rightarrow (C_6H_5)_2CHOR + HBr$$

is given by the well-known equation

$$dx/dt = k\,(a - x)\,(b - x), \tag{1}$$

were x is the diminution of concentration, while a and b are the initial concentrations of the reactants.

The alcohol being in excess, x is negligible with respect to b and equation (1) takes a simpler form, which, being integrated, gives

$$k = \frac{2.303}{bt} \log \frac{a}{a - x} \tag{2}$$

The equation (2) could be written as

$$\log\,(a - x) = -\,\frac{bk}{2.303}\,t - \log a, \tag{3}$$

which makes evident the possibility of determining the rate constant from the slope of the straight line : $\log\,(a - x) = f\,(t)$. The method is illustrated in figure 1 for the case of butyl alcohol at 40° ; k was found to be 0.11 $cm^3\ mol^{-1}\ sec^{-1}$.

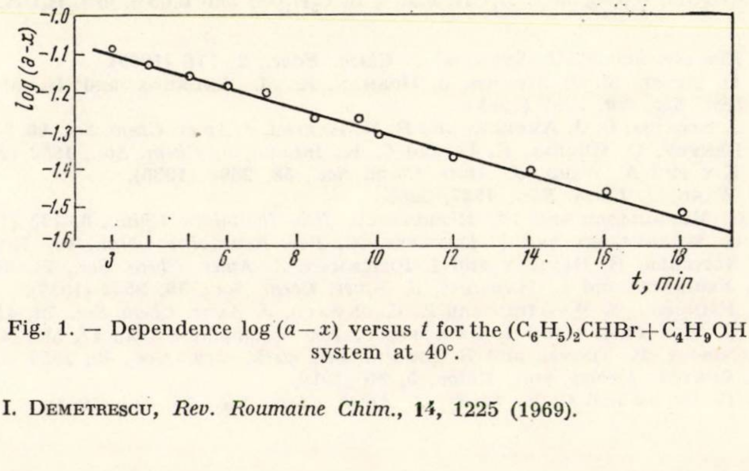

Fig. 1. — Dependence $\log\,(a-x)$ versus t for the $(C_6H_5)_2CHBr + C_4H_9OH$ system at 40°.

---

[16] I. Demetrescu, *Rev. Roumaine Chim.*, **14**, 1225 (1969).

We worked with two initial halide concentrations (0.1 n and 0.2 n) and no change in the value of the rate constants was noticed.

In table 1 we give the rate constants of the alcoholysis reactions between benzhydryl bromide and the first four alcohols of the normal series. It may be seen that the rate constants show a decrease as the chain of alcohol grows longer. The values are much larger than the rate constants of the reactions between benzhydryl chloride and alcohols, convincingly illustrating the reactivity scale of halides in protic solvents ($k_{I^-} > k_{Br^-} > k_{Cl^-}$).

Table 1

Rate constants for the $(C_6H_5)_2CHBr$ + ROH systems
k cm^3 mol^{-1} s^{-1}

Plotting log k *versus* $1/T$ (fig. 2) gave straight lines which enabled us to calculate the energy of activation and the preexponential factor, using the least squares method.

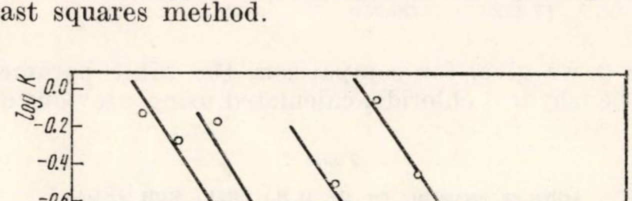

Fig. 2. — Dependence log k versus $1/T$ for the $(C_6H_5)_2CHBr$ + ROH system

1, R=CH_3; *2*, R=C_2H_5; *3*, R=C_3H_7; *4*, R=C_4H_9.

According to the well-known equations of the activated complex theory

$$\Delta^*H = E - RT \tag{4}$$

$$\Delta^*S = 2.303\left(R\log\frac{A}{T} - \log\frac{k}{h}\right) \tag{5}$$

$$\Delta^*G = \Delta H - T\Delta S^* \tag{6}$$

the other activation parameters were calculated. ΔH^* is the variation of the activation enthalpy. ΔS^* the variation of the activation entropy. ΔG^* the variation of the free activation energy, E the activation energy. A the preexponential factor, T the temperature. k, h and R are the Boltzmann's, Planck's and gas constants, respectively.

The activation parameters are listed in table 2.

Table 2

Activation parameters for $(C_6H_5)_2CHBr$ + ROH the systems

iC_3H_7OH	13.956	20210	+ 3.18	19570	18540
iC_4H_9OH	13.35	19410	+ 0.33	18770	18660
i$C_8H_{17}OH$	11.771	17870	− 6.84	17230	19440
sec C_3H_7OH	10.1702	17400	−14.17	16760	21340
sec C_4H_9OH	9.7916	17600	−15.91	16960	22100

As may be seen from the tables 2 and 3, the alcoholysis reactions of the benzhydryl bromide are characterized by much larger activation energies than the corresponding reactions of benzhydryl chloride, denoting that the reactions of bromide are much more influenced by temperature. We also notice differences in the activation entropy, this one being large and positive in the case of the reactions with benzhydryl bromide, and negative as a rule in the case of the reactions with benzhydryl chloride (except for the systems formed with secondary alcohols).

Like in the case of many other related reactions, which do not involve substantial changes in the structure or in the medium characteristics, it can be seen that the enthalpies and entropies of activation given in the tables 2 and 3 verify a linear relation of the form. [17,18]

$$\Delta H^* = \Delta H_0^* + \beta \Delta S^* \qquad (7)$$

where ΔH_0^* is the intercept of the straight line for $\Delta S^* = 0$ and β the slope, having dimensions of a temperature.

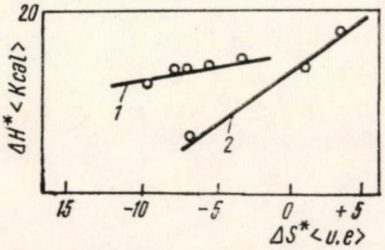

Fig. 3. — Dependence ΔS^* *versus* ΔH^* for the alcoholysis of benzhydryl chloride.

1, $(C_6H_5)_2CHCl + nROH$; *2*, $(C_6H_5)_2CHCl + i-ROH$.

The equation (7) is often called the isokinetic equation as $\Delta G^* = \Delta H^* =$ constant, when $T = \beta$ and the reactions satisfying it have the same speed.

In figure 3 the dependence of ΔS^* on ΔH^* is given for the alcoholysis reactions of benzhydryl chloride; the straight line (1) corresponds to the reactions with normal alcohols and the line (2) to the reactions with isoalcohols.

The results for the alcoholysis of benzhydryl bromide are not conclusive from this point of view.

The two straight lines in figure 3 are not parallel as we might expect for systems of reactions having the same mechanism. Assuming a mixed mechanism [10,19] for the alcoholysis reactions of benzhydryl halides, that difference in slope may be accounted for by the different weights of the unimolecular and bimolecular mechanisms. This mechanism might also explain the variation of the activation entropy, from marked negative values, characteristic for the slow bimolecular reactions between dipoles, to large positive values, contradicting the image of a dipolar activated complex.

The fact that the systems with benzhydryl bromide do not verify the Laidler-Eyring equation, [20] the plot of log k as a function of the

Kirkwood ratio $(D - 1)/(2D + 1)$ being not a straight line as it was in the case of systems with benzhydryl chloride, [8,21] may be accounted for, in the same way, accepting the mixed mechanism.

In conclusion, we can assert, taking also into account the data concerning, the solvolysis of benzhydryl halides, [1-11] the salt effects, and the mass law effect, that these solvolyses imply, besides the bimolecular mechanism, more or less pronounced characteristics of the monomolecular mechanism.

SOLVENT EFFECT ON THE ANHARMONICITY OF THE C=O VIBRATION OF ACETOPHENONE AND BENZOPHENONE

V. E. SAHINI and MARINA OLTENEANU

Centre of Physical Chemistry, Ministry of Education
Galaţi 31, Bucharest, Romania

Received October 10, 1972

We studied the effect of weak hydrogen bond formation on the mechanical and electrical anharmonicity of the C = O vibration. On passing from interaction such as collision complexes to interactions by means of weak hydrogen bonds the C = O vibration becomes more harmonic.

Many theoretical works consider that the modifications of the mechanical and electrical anharmonicity are responsible to some extent for the important perturbations of the stretching vibrations of polar vibrators. [1,2,3]

Earlier experimental results obtained by Lüttke, Mecke and Greinacher [4] for water in various organic bases show that the effect of hydrogen bond formation is to decrease the mechanical anharmonicity as compared to that of the gaseous monomer.

Bell and Barrow [5] assigned the splits of the bands corresponding to the overtones of the ν_{OH} of methanol and phenol to the existence of two minima of the potential surfaces, using an explanation given by Detoni and Hadži [6] and Blinc and Hadži. [7]

Sokolov [8] pointed out that the existence of two potential minima is hardly probable.

In a more recent work, Barrow [9] explained these splits by Fermi resonance between the overtones of ν_{OH} stretching vibrations and a combination which involves the OH deformation mode.

[9] G. M. Barrow, *Spectrochim. Acta*, **16**, 799 (1960).

Experimentally there is no doubt on the existence of these splits for strong hydrogen bonds. Possibly the low values obtained by different authors for the anharmonicity are due to the fact that they used for calculations the stronger high frequency band.

Barthomieu and Sandorfy,[10] Durocher and Sandorfy[11] and Foldes and Sandorfy[12] undertook a more sistematical study of the overtones of the ν_{OH} and ν_{NH} stretching vibrations.

By comparing the frequencies of the ν_{NH} fundamentals and of overtones of some secondary amines in pure liquids and in carbon tetrachloride solutions they found that the self-association leads to a decrease of the mechanical anharmonicity of the first overtone.

For stronger hydrogen bonds (alcohols, phenol) Durocher, Foldes and Sandorfy found for multimer that the mechanical anharmonicity is approximately twice that for the monomer vibration ν_{OH}.

Couzi and van Huong,[13] in a study concerning the change of the anharmonicity of ν_{OH} vibration of phenol, found that in nonpolar solvents the anharmonicity values are roughly the same as for the gas phase. For weak hydrogen bonds there is a decrease, while in strong accepter proton solvents the mechanical anharmonicity increases markedly.

Lüttke, Mecke, Barthomieu and Sandorfy[14] found an important decrease of the electrical anharmonicity for the ν_{OH} and ν_{NH} vibrations.

On the contrary, Couzi and van Huong[13] showed that the apparent absorption intensity of the band corresponding to the first overtone of the ν_{OH} vibration is markedly weaker as that of the fundamental and is in no way influenced by the molecular interactions.

We have considered interesting to follow the influence of some interactions through weak hydrogen bonds upon the overtones of the $C = O$ vibrator for benzophenone and acetophenone.

EXPERIMENTAL

The benzophenone p.a. was recrystallized several times from ethanol. The acetophenone p.a. was purified by successive recrystallizations and carefully dried.

The solvents, spectrochemical grade, were dried on molecular sieves (4 Å, Carlo Erba) and distilled under molecular sieves just before use.

The used concentrations were 0.05 M/L for the fundamentals and 0.5 M/L for the overtone region.

The spectra were recorded with a U.R. 10 C Zeiss-Jena spectrophotometer. The wavelength calibration was made with water vapours and the linearization was made electronically.

The apparent integrated intensities were calculated without wing corrections.

[14] W. Lüttke and R. Mecke, *Z. Electrochem.*, **53**, 241 (1949).

RESULTS AND DISCUSSION

The bands corresponding to $\nu_{C=O}$ stretching vibrations of benzophenone and acetophenone in carbon tetrachloride are symmetrical and become more asymmetrical by solving the compounds in dichloromethane, dibromomethane and chloroform.

The bands corresponding to the first overtone, $2\nu_{c=o}$, for both ketones are symmetrical, except if we use chloroform as a solvent.

Using mixed solvents for studying the shape of the bands corresponding to the first overtone we did not observe the appearance of submaxima, contrary to the facts observed by Josien and co-workers [15] and by us [16] for the fundamentals.

The absorption maxima of the fundamentals and overtones do not shift with solvent change in pure solvents.

Table 1 show the frequencies of the fundamentals and overtones and the mechanical anharmonicities calculated from these frequencies for both ketones in the considered solvents.

Table 1

Frequencies of the fundamentals and of the first overtones and the mechanical anharmonicity of the C = O vibration for benzophenone and acetophenone

	Acetophenone			Benzophenone		
solvent	$\nu_{01(cm^{-1})}$	$\nu_{02(cm^{-1})}$	$\omega_e x_e$	$\nu_{01(cm^{-1})}$	$\nu_{02(cm^{-1})}$	$\omega_e x_e$
CCl_4	1692	3359	14	1667	3308	13
CH_2Cl_2	1683	3349	9	1657	3298	8
CH_2Br_2	1681	3343	10	1656	3295	9
$CHCl_3$	1681	3347	8	1656	3297	8

It can be observed that by solving benzophenone and acetophenone in dichloromethane, dibromomethane and chloroform there is a decrease of the mechanical anharmonicity for the C = O vibrator relative to that calculated for both ketones in carbon tetrachloride.

To account for the behaviour of the electrical anharmonicity we study the shape of the absorption bands corresponding to the fundamentals $\nu_{C=O}$ and the overtones $2\nu_{C=O}$.

From tables 2 and 3 one can observe that the apparent integrated intensity of the fundamental vibrations rises by an order of magnitude at hydrogen bond formation in agreement with the results for other compounds containing C = O group. For the overtones there is no change on passing from the nonpolar solvent to the polar ones, in agreement

	ν_{01}			ν_{02}			A''_{02}/A''_{01}
solvent	$\varepsilon_1(1\cdot mol^{-1}cm^{-1})$	$A''_{01}(1\cdot mol^{-1}\ cm^{-2})$	$^1\Delta\nu_{1/2}(cm^{-1})$	$\varepsilon_2\,(1\cdot mol^{-1}\ cm^{-1})$	$A''_{02}\,(1\cdot mol^{-1}\,cm^{-1})$	$^2\Delta\nu_{1/2}\ (cm^{-1})$	
CCl_4	1321	1184	11.7	11.6	278	25	0.23
CH_2Cl_2	1162	12.612	14	9.7	265	27	0.02
CH_2Br_2	1142	13.119	14.6	9.6	295	34	0.02
$CHCl_3$	1009	17.886	18.6	8.3	280	42	0.01

with the results of van Huong and Couzi [13] for the first overtone of the ν_{OH} stretching vibration of phenol.

Thus for benzophenone the values of the apparent integrated intensities are approximately 280 L mol^{-1} cm^{-2} and for acetophenone, 300 L mol^{-1} cm^{-2}.

It is well konwn that the existence of an electrical anharmonicity in a diatomic molecule leads to a nonlinear dependence of the dipole moment variation on the internuclear distance and M can be expressed as :

$$M = M_0 + M_1 r + M_2 r^2 + M_3 r^3 + \dots$$

Neglecting the higher terms, Russel and Thomson [17] have showed that in the diatomic oscillator approximation we can write

$$(A_{02}/A_{01}) = X_e\, 1 - (2B/ar_e)^2$$

where $B = M_2/M_1$ and a is the Morse constant in the potential function. From the values of the ratios A_{02}/A_{01} we can see that there is an important decrease of the electrical anharmonicity of the $C = O$ group for both ketones in CH_2Cl_2, CH_2Br_2 and $CHCl_3$.

From tables 2 and 3 one can also observe a decrease of the molar extinction coefficients of the fundamentals, in agreement with earlier results.

For the corresponding overtones, there is an important decrease as compared with those of the fundamentals (by two orders of magnitude) but the values are of the same order of magnitude for carbon tetrachloride and for the polar solvents.

The small decrease observed on passing from carbon tetrachloride to chloroform follows the increase in the hydrogen bond strength. One can also see from tables 3 and 4 that the values of the half bandwidths of the overtones are twice those for the fundamentals, both for the nonpolar solvent and the polar one. Attempts to correlate these latter values to those of the apparent integrated intensities and molar extinction coefficients has not led to any significant results.

CONCLUSIONS

1. On passing from interactions such as collision complexes to interactions by means of weak hydrogen bonds, there is a decrease of the mechanical anharmonicity of the $C = O$ vibration for the ketones under consideration.

2. The molar extinction coefficients of the overtones and the ratios of the apparent integrated intensities of the overtones and fundamentals decrease with the increase of the hydrogen bonding strength.

Therefore, in the cases discussed above for the interactions, by means of weak hydrogen bonds, the $C = O$ vibration becomes more harmonic.

with the results of van Thong and [illegible] for the first overtone of the [illegible] stretching vibration of phenol.

For the fundamentals the values of the apparent integrated intensities are approximately 260 L mol^{-1} cm^{-2} and for the overtones [illegible] L mol^{-1} cm^{-2}.

It is well known that the intensity of an vibrational transition of a diatomic molecule leads to a nonlinear dependence of the dipole moment variation on the internuclear distance and M can be expressed as

$$M = M_0 + M_1 [illegible] + M_2 [illegible] \ldots$$

Neglecting the higher terms, Russell and Thompson[illegible] have shown that in the harmonic oscillator approximation one can write:

$$[illegible]$$

where $\beta = M_2/M_1$ and a is the Morse constant in the potential function. From the values of the ratios A_2/A_1 we can see that there is an important decrease of the electrical anharmonicity of the [illegible] group for both ketones in CH_2Cl_2, CH_2Br_2 and $CHCl_3$.

From tables 2 and 3 one can also observe a decrease of the molar extinction coefficients of the fundamentals, in agreement with earlier results.

For the corresponding overtones, there is an important decrease as compared with those of the fundamentals (by two orders of magnitude) but the values are of the same order of magnitude in carbon tetrachloride and for the polar solvents.

The small decrease observed on passing from carbon tetrachloride to chloroform follows the increase in the hydrogen bond strength. One can also see from tables 3 and 4 that the values of the half band-widths of the overtones are twice those for the fundamentals, both for the non-polar solvent and the polar one. Attempts to correlate these latter values to those of the apparent integrated intensities and molar extinction coefficients has not led to any significant results.

CONCLUSIONS

1. On passing from intermolecular [illegible] as collision complexes to [illegible] by means of weak hydrogen bonds, there is a decrease of the mechanical anharmonicity of the C=O vibration for the ketones under consideration.

2. The molar extinction coefficients of the overtones and the ratios of the apparent integrated intensities of the overtones and fundamentals decrease with the increase of the hydrogen bonding strength.

Therefore, in the cases discussed above for the interactions by means of weak hydrogen bonds, the C=O vibration becomes more harmonic.

SIMULTANEOUS DETERMINATION BY KNUDSEN EFFUSION-MICROCALORIMETRIC TECHNIQUE OF THE VAPOUR PRESSURE AND SUBLIMATION ENTHALPY OF ANTIMONY TRIFLUORIDE. VAPOUR PRESSURE OF BISMUTH TRIFLUORIDE

G. DE MARIA, L. MALASPINA, G. BARDI and R. GIGLI

Laboratorio di Chimica-Fisica ed Elettrochimica, Istituto Chimico, Università di Roma, Roma, Italy

Received September 22, 1972

The Knudsen vapour pressure and sublimation enthalpy of SbF_3 were simultaneously determined on the temperature range 375–455 K utilizing a Calvet microcalorimeter, with a method based on the differential calorimetry combined with the Knudsen effusion technique. The relative equations on the investigated temperature range are as follows:

$$\Delta H^0_{sub}(T) = (25987 \pm 36) - (5.28 \pm 0.09)\,T \text{ cal mole}^{-1}$$

$$\log_{10} p_{torr} = (11.48 \pm 0.06) - (5176 \pm 23)/T.$$

The sublimation enthalpy values at 298 K obtained from the microcalorimetric data and by second and third-law treatment of the vapour pressure data are: ΔH^0_{298} (calorimetric) = 24407 ± 71 cal mole^{-1}, ΔH^0_{298} (second-law) = 24385 ± 105 cal mole^{-1} and ΔH^0_{298}(third-law) = 24409 ± 54 cal mole^{-1}. The thermodynamic functions of $SbF_{3(g)}$ molecule were also evaluated on the temperature range 298–1000 K. The vapour pressure values of BiF_3 were determined on the temperature range 669–838 K utilizing a vacuum thermobalance. The data relative to the sublimation process are as follows:

$$\log_{10} p_{torr} = (11.79 \pm 0.09) - (9797 \pm 70)/T;$$

$$\Delta H^0_{298} \text{ (second-law)} = 47726 \pm 320 \text{ cal mole}^{-1};$$

$$\Delta H^0_{298} \text{ (third-law)} = 48077 \pm 233 \text{ cal mole}^{-1}.$$

INTRODUCTION

There is little information in the literature about the vapour pressure and the sublimation enthalpy of the antimony and bismuth trifluorides. These compounds have been investigated only by Cubicciotti [1,2] by means of a transpiration method. In the present work, the antimony trifluoride has been studied utilizing a method based on the combination

---

[1] D. Cubicciotti, *High Temp. Sci.*, **1**, 268 (1969).

[2] D. Cubicciotti, *J. Electrochem. Soc.*, **115**, 1138 (1968).

of the microcalorimetry with the classical Knudsen effusion technique. This method allows to obtain simultaneously, the values of vapour pressures and sublimation enthalpy of the compound investigated at well-known temperatures.

Using this procedure, already successfully applied to cadmium, [3] zinc and tellurium [4] and to benzoic acid and anthracene, [5] the sublimation enthalpy value, directly determined by microcalorimetry, can be compared with the values obtained by the second and third-law treatment of the vapour pressure data.

Due to a temperature range too high for the employment of the apparatus utilized for the antimony trifluoride, the vapour pressure of bismuth trifluoride was determined by measuring the rate of mass loss in Knudsen conditions, using a thermobalance.

EXPERIMENTAL

A. SbF_3

The microcalorimetric measurements were carried out utilizing a SETARAM Calvet differential microcalorimeter [6] described elsewhere. [7] The two twin microcalorimeter elements are placed symmetrically in a kanthal block, and the differential thermal flow is measured by means of two thermopiles in opposition, each one consisting of 396 Pt; Pt – 10% Rh thermocouples and connected with a galvanometer. The thermogram is recorded by means of a spot following recorder actuated by the same galvanometer. The assembly utilized for the evaporation experiment, consisting of two identical devices placed in the working and reference cells of the microcalorimeter, is described in detail in previous works. [3-5] The proportionality between thermal power and galvanometric deflection i.e. the instrument constant (P/Δ), was determined by Joule effect [3-5] at each experimental temperature.

The temperatures were measured by a previously calibrated Pt; Pt – 10% Rh thermocouple placed in the center of the calorimetric block.

B. BiF_3

The rate of mass loss in the Knudsen conditions of the samples was measured by means of a null Ugine-Eyraud mod. B. 60 SETARAM microbalance. The reaction chamber, a silica-glass tube, 60 cm high and 17 mm in diameter, was heated along its whole length by means of a cylindrical coaxial graphite resistance. The Knudsen cells were suspended to the balance beam and placed in the center of the isothermal zone of the reaction chamber (about 15 cm long) determined in a former experiment. The mass loss of the samples was recorded at temperatures maintained constant within $\pm 1°$ by means of an efficient thermoregulation device.

The temperatures of the samples were measured with a previously calibrated Pt; Pt – 10% Rh thermocuple inserted in an identical cell placed immediately beneath the effusion cell and recorded simultaneously with the sample loss. A differential pumping system for the reaction chamber, balance housing and for the furnace allowed to obtain a vacuum of not less than 1×10^{-5} torr. Both compounds 99.99% purity, Alfa Inorganics Co., were evaporated in platinum Knudsen cells, with effusion holes of different diameter (see Tables 3 and 4) drilled into platinum sheets 0.1 mm thick.

RESULTS

A. VAPOUR PRESSURE AND SUBLIMATION ENTHALPY OF $SbF_3(s)$

The simultaneous measurements of the sublimation enthalpy and of the vapour pressure were carried out by measuring the area of the thermogram relative to the quantitative evaporation in the Knudsen conditions of the sample with the same experimental procedure used in the previous works.[3-5] The investigated temperature range was 375 to 455 K. Use was made of the well-known expressions

$$\Delta H^0_{\text{sub}}(T) = 1/4.186 \, \frac{M}{m} \, (P/\Delta)\,(A/v) \tag{1}$$

$$p_{(\text{torr})} = \frac{2.256 \times 10^{-2} \times 760}{S} \, (\mathrm{d}m/\mathrm{d}t)\,(T/M)^{1/2}(1/K) \tag{2}$$

where

$\Delta H^0_{\text{sub}}(T)$ = the value of sublimation enthalpy at absolute temperature T (cal mole^{-1})
p = vapour pressure (torr)
m = mass of the sample evaporated (g)
P/Δ = microcalorimeter constant (watt mm^{-1})
A = area of the thermogram (mm^2)
v = recording speed of the thermogram (1/12 mm s^{-1})
S = effusion hole area (cm^2)
$(\mathrm{d}m/\mathrm{d}t)$ = rate of mass loss (g s^{-1})
K = Clausing correction factor[8]

According to the mass spectrometric investigation by Cubicciotti[1] we considered that within the investigated temperature range the vapour phase in equilibrium with the condensed SbF_3 consists only of SbF_3 molecules.

In order to check the reproducibility of the data, three vaporizations were carried out at each temperature. The values of the sublimation enthalpy so determined and the mean values are given in Table 1. The least square treatment of the experimental mean values of $\Delta H^0_{\text{sub}}(T)$ as function of T (plotted in Figure 1) gives the equation

$$\Delta H^0_{\text{sub}}(T) = (25987 \pm 36) - (5.28 \pm 0.09)\,T. \tag{3}$$

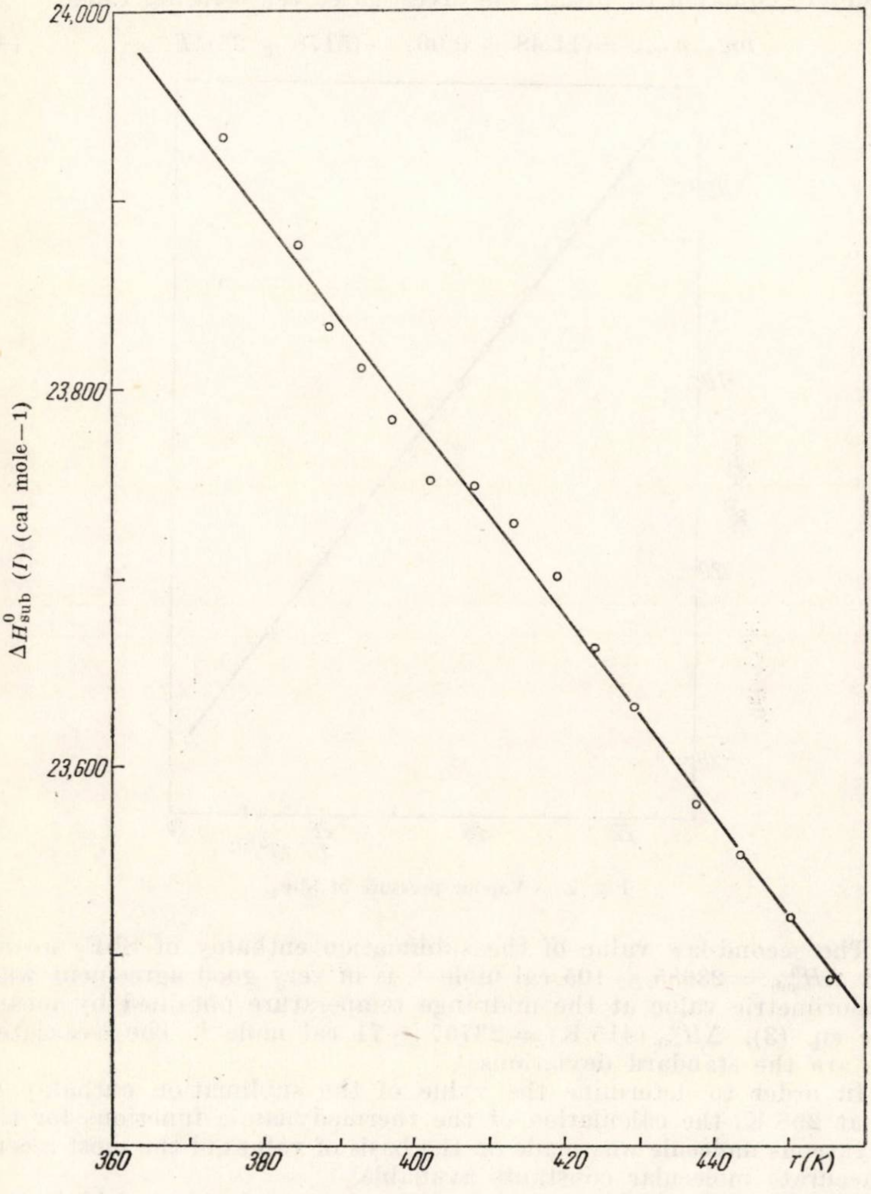

Fig. 1. — Sublimation enthalpy of SbF_3 determined by microcalorimetry.

The experimental average vapour pressure values of SbF_3 are listed in Table 3 and plotted as function of $1/T$ in Figure 2. The relative least square equation is, within the investigated temperature range

$$\log_{10} p_{(\mathrm{torr})} = (11.48 \pm 0.06) - (5176 \pm 23)/T. \qquad (4)$$

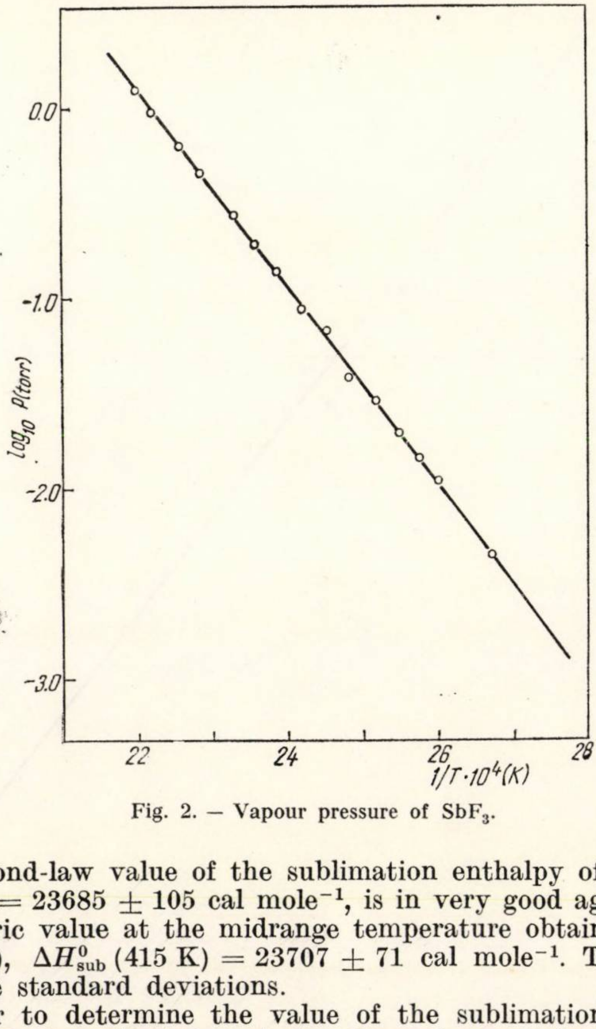

Fig. 2. — Vapour pressure of SbF_3.

The second-law value of the sublimation enthalpy of SbF_3 so obtained $\Delta H^0_{\mathrm{sub}} = 23685 \pm 105$ cal mole^{-1}, is in very good agreement with the calorimetric value at the midrange temperature obtained by means of the eq. (3), $\Delta H^0_{\mathrm{sub}}$ (415 K) $= 23707 \pm 71$ cal mole^{-1}. The associated errors are the standard deviations.

In order to determine the value of the sublimation enthalpy of SbF_3 at 298 K, the calculation of the thermodynamic functions for the SbF_3 gaseous molecule was made on the basis of values of the most recent and accurate molecular constants available.

A pyramidal structure and a symmetry number $\sigma = 3$ [1,9-11] was assumed for the SbF_3 molecule. The Sb-F values for internuclear $d_{\mathrm{Sb-F}} =$

1000	80.93	16586	93.93	19.409

The aforementioned second-law and calorimetric sublimation enthalpy of SbF_3 at the midrange temperature were thus reduced to 298 K utilizing the heat content values determined in this work for SbF_3 (g) and those reported by Cubicciotti [1] for the condensed phase. These values are ΔH^0_{sub} (298 K) (second-law) $= 24385 \pm 105$ cal $mole^{-1}$ and ΔH^0_{sub} (298 K) (calorimetric) $= 24407 \pm 71$ cal $mole^{-1}$.

The third-law treatment of the experimental vapour pressure data determined in this work is shown in Table 3. The $(G^0_T - H^0_{298})/T$ values calculated in this work for SbF_3 (*g*) and those reported in literature for solid SbF_3 were utilized. One obtains an average value of ΔH^0_{sub} (298 K) $=$ $= 24409 \pm 54$ cal $mole^{-1}$.

B. VAPOUR PRESSURE OF $BiF_3(s)$

The thermogravimetric measurement of the vapour pressure of BiF_3 (*s*) was carried out on the temperature range 669 to 838 K. The vapour phase in equilibrium with the solid trifluoride was also assumed to be composed only of BiF_3 molecules on the investigated temperature range.[2]

The vapour pressure values obtained by utilizing the eq. (2) are listed in the Table 4.

The $\log p$ vs $1/T$ plot is shown on Figure 3. The least-square treatment of the experimental data gives, within the investigated temperature range, the equation

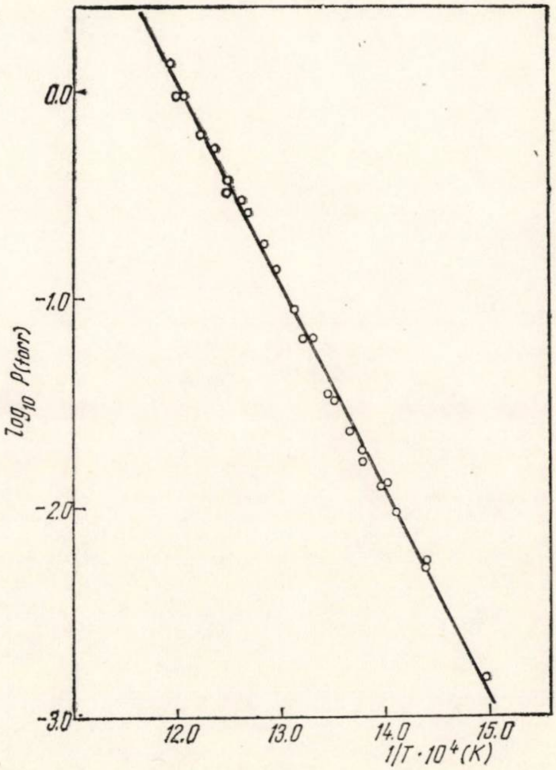

Fig. 3. — Vapour pressure of BiF_3.

$$\log_{10} p_{(\mathrm{torr})} = (11.79 \pm 0.09) - (9797 \pm 70)/T. \qquad (5)$$

The relative second-law value of the sublimation enthalpy of BiF_3 is $\Delta H^0_{\mathrm{sub}}(745\ \mathrm{K}) = (44832 \pm 320)$ cal mole^{-1}.

The corresponding value at 298 K, obtained utilizing the heat content data reported by Cubicciotti[2] for the condensed and vapour phases, is $\Delta H^0_{\mathrm{sub}}(298\ \mathrm{K}) = (47726 \pm 320)$ cal mole^{-1}. The third-law treatment of the experimental vapour pressure data, utilizing the free energy function values reported in the literature[2] is also given in Table 4. An average value of $\Delta H^0_{\mathrm{sub}}(298\ \mathrm{K}) = (48077 \pm 233)$ cal mole^{-1} for the bismuth trifluoride was obtained.

ISOTHERMAL EQUILIBRIUM AND CALCULATION OF EXCESS FUNCTIONS IN THE BENZENE-ISOBUTYL ALCOHOL SYSTEM

RODICA VÎLCU and ZOICA CENUȘE

Chair of Chemical Thermodynamics and Electrochemistry, Bucharest University,
Bd. Republicii 13, Romania

Received October 12, 1972

Isothermal vapour-liquid equilibria were measured in the benzene-isobutyl alcohol system at 45 and 55°. The measured data were employed to calculate the values of excess quantities.

Recently, a considerable effort has been made to formulate more general rules governing the behaviour of components of binary mixtures in the vapour – liquid phase equilibrium which could substitute the somewhat lengthy experimental procedures. This effort is based primarily on a detailed descriptive study of binary systems of suitably chosen homologous series. Attention is paid mainly to systems displaying considerable deviations from ideal behaviour, e.g. mixtures of polar substances with nonpolar ones.

The study of the benzene-butyl alcohols binary systems was started with the aim to contribute to this kind of description. The present work presents the results of the measurement of the isothermal vapour-liquid equilibria of the benzene-isobutyl alcohol system at 45 and 55°.

EXPERIMENTAL

PREPARATION OF PURE SUBSTANCES

Benzene of the reagent grade purity for cryoscopy (Belgium) was used; the water content with Karl-Fischer reagent was 0.00336%.

Isobutyl alcohol was a pure reagent (Austria) which was redistilled; only after this distillation the physical constants were in good agreement with the literature data; the water content with Karl-Fischer reagent was 0.00455%.

The physical properties of the reagents were indicated in table 1.

Table 1

Physical properties of the reagents

Substance	Refractive index (n_D^{25})		Boiling point (°C)		d (g/ml)		P_c (atm)	T_c (°C)
	experimental	liter.	experimental	liter.	experimental	liter.		
benzene	1.4975	1.49715[1]	80.1	80.07 [2]	0.8738	0.8740 [2]	50.1 [4]	290.5 [4]
isobutyl alcohol	1.3940	1.3938 [2]	107.8	108.01 [2]	0.7985	0.7979 [3]	42.39 [5]	276.7 [5]

ANALYSIS OF MIXTURES

Composition of the equilibrium mixture was determined by measuring the refractive index at 25° with an Abbé refractometer having a precision of about $\pm 2.10^{-4}$. In this case a calibration graph was necessary.

Results of the measurements are presented in table 2 and in figure 1.

APPARATUS

The apparatus which was set up for measurements was one of Swietoslawsky equilibrium type previously described in detail.[6]

The temperature was adjusted with a thermoregulator to ± 0.05°.

Two cylinders, one of 2 l and another of 60 l served as vacuum reservoires. Regulation of pressure was attained handly with a capilar stopcock by means of a manometer, allowing to read pressure with a precision of about 1 mm Hg, which was satisfactory with respect to the fact that heating system permitted to control the temperature with an accuracy of ± 0.05°.

EXPERIMENTAL RESULTS

The measurements in the benzene-isobutyl alcohol system rises no difficulty and the experimental data were indicated in the table 3 and in figures 2 and 3.

In the effort to introduce into the calculations a correction for the real behaviour of the vapour phase we calculated the activity coefficients with the relation:

$$\ln \gamma_i = \ln x_i^V P / x_i^L P_i^0 + (B_{ii} - V_i)(P - P_i^0)/RT + P\delta_{ij}(1 - x_i^V)^2/RT \quad (1)$$

where

$$\delta_{ij} = 2B_{ij} - B_{ii} - B_{jj}$$

For pure nonpolar gases an excellent correlation for the second virial coefficient B_{ii} has been given by Pitzer and Curl[9] based on the theorem of corresponding states. It has the form

$$P_{c_i} B_{ii} / RT_{c_i} = f_B^{(0)}(T_r) + \omega_i f_B^{(1)}(T_r) \quad (2)$$

where P_{c_i} is the critical pressure of i, T_{c_i} is the critical temperature of i, ω_i is the acentric factor of i and T_r is the reduced temperature, T/T_{c_i}. The acentric factor is defined by

$$\omega_i = -\log(P_i^s / P_{c_i}) - 1.000 \quad (3)$$

where P_i^s is the saturation vapour pressure of i at $T/T_{c_i} = 0.7$. The empirically determined functions $f_B^{(0)}(T_r)$ and $f_B^{(1)}(T_r)$ are

$$f_B^{(0)}(T_r) = 0.1445 - 0.330/T_r - 0.1385/T_r^2 - 0.0121/T_r^3 \quad (4)$$

$$f_B^{(1)}(T_r) = 0.073 + 0.46/T_r - 0.50/T_r^2 - 0.097/T_r^3 - 0.0073/T_r^8 \quad (5)$$

For pure polar gases O'Connell and Prausnitz[10] have developed a new empirical correlation on an extended corresponding states theorem of the form

$$P_{c_i} B_{ii} / RT_{c_i} = f_B^{(0)}(T_r) + \omega_{H_i} f_B^{(1)}(T_r) + f_\mu(\mu_R, T_r) + \eta_i f_a(T_r) \quad (6)$$

The symbol ω_{H_i} stands for the acentric factor of the polar component homomorph (a homomorph of a polar molecule is a nonpolar molecule having approximately the same size and shape as those of the polar molecule).

The empirical function $f_\mu(\mu_R, T_r)$ depends on the reduced temperature T_r and on the reduced dipole moment defined by

$$\mu_R = 10^2 \mu_i^2 P_{c_i} / T_{c_i}^2 \quad (7)$$

---

[9] K. S. Pitzer and R. F. Curl, *J. Amer. Chem. Soc.*, **79**, 2369 (1957).

[10] J. P. O'Connell and J. M. Prausnitz, *Ind. Eng. Chem. Proc. Design. and Development*, **6**, 245 (1967).

where μ_i is the dipole moment of component i in Debye units.

For $\mu_R > 4$ f_μ is given by

$$\begin{aligned} f_\mu(\mu_R, T_r) = &- 5.237220 + 5.665807 (\ln \mu_R) - 2.133816 (\ln \mu_R)^2 + \\ &+ 0.2525373 (\ln \mu_R)^3 + 1/T_r x [5.769770 - 6.181427 (\ln \mu_R) + \\ &+ 2.283270 (\ln \mu_R)^2 - 0.2649074 (\ln \mu_R)^3] \end{aligned} \tag{8}$$

Equation (8) is not applied for molecules of very low polarity ($\mu_R < 4$) because of the logaritmic terms and for such molecules one should use $f_\mu(\mu_R, T_r) = 0$, as in our case.

$$(\mu_{\text{isobutyl alcohol}} = 1.64).$$

The association constant η_i is an empirically determined quantity which reflects the tendency of a component, e.g. alcohols, to associate with itself. The association function is given by

$$f_a(T_r) = \exp [6.6 (0.7 - T_r)] \tag{9}$$

The values of η_i are determined by Prausnitz, from the difference between experimental data and results obtained from the equations (4), (5) and (6).

The form of equation (9) is governed by the behaviour of the most associating substances. Generally, the association function contributes with a significant quantity to the total second virial coefficient at a temperature near and below the normal boiling point.

In order to estimate cross coefficient, B_{ij}, the previously presented correlating equations for pure components, we used with suitable combinatory rules for the various parameters. When i is a polar substance and j is a nonpolar one, equations (4), (5) and (8) are used for B_{ij}, where for $T_{c_{ij}}$ is used equation

$$T_{c_{ij}} = (T_{c_i} \cdot T_{c_j})^{1/2} \tag{10}$$

For ω_{ij} Prausnitz used

$$\omega_{ij} = (\omega_{H_i} + \omega_j)/2 \tag{11}$$

Equation (12) is used for $P_{c_{ij}}$

$$P_{c_{ij}} = 4T_{c_{ij}}[P_{c_i} \cdot V_{c_i}/T_{c_i} + P_{c_j} \cdot V_{c_j}/T_{c_j}]/(V_{c_i}^{1/3} + V_{c_j}^{1/3})^3 \tag{12}$$

where V_c is the critical volume.

If reliable critical volume data are not available, they should be estimated with the relation

$$V_c = RT_c(0.293 - 0.08\ \omega)/P_c \tag{13}$$

The calculated values of the second virial coefficient of benzene, B_{11} and of isobutyl alcohol, B_{22}, are tabulated in tables 5 and 6.

Table 5

The values of the second virial coefficient B_{11} at 45 and 55°

Substance	Temperature (°C)	B_{11} (ml/mol)	ω	d (g/ml)	M(g)	V(ml/mol)
benzene	45	−1245.08	0.211	0.8575 [11]	78.114	93.13
	55	−1145.12	0.211	0.83870 [11]	78.114	98.82

Table 6

The values of the second virial coefficient B_{22} at 45 and 55°

Substance	Temp (°C)	B_{22} (ml/mol)	ω	d(g/ml)	M(g)	V(ml/mol)	$\mu_R^{(D)10}$	η_i^{10}
isobutyl	45	−194.19	0.215	0.78327 [3]	73.116	93.34	1.64	0.49

	Margules 3	8.761	−18.589

From the mentioned equilibrium data the excess quantities G^E (cal/mol) were estimated and the values are given in table 10 as well as in figure 5.

These data presented a maximal value for 45° at $x^L_{C_6H_6} = 0.24$ and $G^E = 517.44$ cal/mol and for 55° at $x^L_{C_6H_6} = 0.26$ and $G^E = 346.68$ cal/mol.

Table 10

The values of G^E cal/mol) for the benzene-isobutyl alcohol system at 5 and 55°

SIGNIFICANT STRUCTURES THEORY OF IONIC BINARY LIQUID MIXTURES: HEAT CAPACITIES, COMPRESSIBILITY COEFFICIENTS AND THERMAL-EXPANSION COEFFICIENTS

RODICA VÎLCU and C. MISDOLEA

Physico-Chemical Institute, str. Galaţi 31, Bucharest, Romania

Received October 2, 1972

The heat capacity at constant volume, as well as the compressibility and the thermal-expansion coefficient of the binary systems of molten salts K(Cl—Br), Na(Cl—Br) and Cl(Na—K) were calculated at 1073 K, 1173 K and 1273 K, by taking the theory of significant structures as a model of the liquid state. The computed data allow, by comparing them with the experimental data, to discuss some aspects of the theory.

INTRODUCTION

The heat capacity, the thermal-expansion coefficient and the compressibility coefficient can offer, for any model of the liquid state, conclusive verifications. By computing these quantities, the partition function, at which the considered model arrives, can be more thoroughly analysed because the expressions contain derivatives of the first and second order in respect to the temperature as well as to the volume. This permits to verify the hypothesis of the theory and the manner of expressing mathematically these hypotheses. In a previous paper, [1] we computed these quantities for the ionic liquids KCl, KBr, NaCl, and NaBr, the model under study being the theory of the significant structures. [2] When the theory is extended to binary systems [3,4] the computation of the heat capacity, of the thermal — expansion coefficient and of the compressibility constitutes a still more necessary verification.

The partition function of an ionic liquid, according to the theory of significant structures, is [2]

$$Z_i = \left\{ \frac{\exp\left[(E_{s_i}/2RT)(V_i/V_{s_i})^{1/3}\right]}{[1-\exp(-\theta_i/T)]^3} \left[1 + n_{h_i} \exp\left(-\frac{a_i E_{s_i} (V_i/V_{s_i})^{1/3}}{2n_{h_i} RT}\right)\right]\right\}^{2N\frac{V_{s_i}}{V_i}} \times \tag{1}$$

$$\times \left[\frac{(2\pi m_i kT)^{3/2}}{h^3} \frac{8\pi^2 I_i kT}{h^2} \frac{1}{1-\exp(-h\nu_i/kT)} \frac{\mathrm{e}V_i}{N}\right]^{N\frac{V_i - V_{s_i}}{V_i}}$$

In this formula, as well as in the following ones, index *i* takes the values 1 or 2, according to whether it concerns the liquid 1 or 2 as constituent of the binary system. The quantities appearing in the expression of the partition function are :

E_{s_i},	the sublimation energy at the melting point
θ_i,	the Einstein characteristic temperature of the solid at the melting point
V_i,	the molar volume of the liquid
V_{s_i},	the molar volume of the solid at the melting point
n_{h_i},	the supplementary number of accesible positions of a molecule, besides the equilibrium position

$$n_{h_i} = n_i \frac{V_i - V_{s_i}}{V_{s_i}}, \quad n_i = C_i \frac{V_{s_i}}{V_i}$$

where C_i is the coordination number

a_i,	a parameter related to the energy necessary to a molecule for occupying one of its accessible positions
m_i,	the mass of the molecule
I_i,	the moment of inertia of the diatomic gaseous salt molecule
ν_i,	the vibration frequency of the gaseous molecule in its fundamental state.

The Helmholtz free energy of a mole of liquid, $F_i = -RT \ln Z_i$ is expressed by

$$F_i = -RT\left[\frac{2}{x_i}(\sigma_1^{(i)} + \sigma_2^{(i)} - \eta_i) + \left(1 - \frac{1}{x_i}\right)\left(\gamma_i + \ln \frac{eV_{s_i}}{N} x_i\right)\right] \tag{2}$$

where $x_i = V_i/V_{s_i}$, with the notations

$$\sigma_1^{(i)} = \frac{E_{s_i}}{2RT} x_i^{1/3} \tag{3}$$

$$\sigma_2^{(i)} = \ln\left[1 + n_i(x_i - 1)\exp\left(-\frac{a_i E_{s_i}}{2n_i RT}\,\frac{x_i^{1/3}}{x_i - 1}\right)\right] \tag{4}$$

$$\eta_i = 3\ln\left[1 - \exp\left(-\theta_i/T\right)\right] \tag{5}$$

$$\gamma_i = \ln\left[\frac{(2\pi m_i kT)^{3/2}}{h^3}\,\frac{8\pi^2 I_i kT}{h^2}\,\frac{1}{1 - \exp(-h\nu_i/kT)}\right] \tag{6}$$

Since the heat capacity at constant volume is equal to the internal energy variation, with regard to the temperature, whose expression is

$$U_i = RT^2\,(\partial \ln Z_i/\partial T)v \tag{7}$$

we shall obtain

$$C_{v_i} = \frac{RT}{x_i}\left[4\left(\frac{\partial\sigma_1^{(i)}}{\partial T} + \frac{\partial\sigma_2^{(i)}}{\partial T} - \frac{\partial\eta_i}{\partial T}\right) + 2T\left(\frac{\partial^2\sigma_1^{(i)}}{\partial T^2} + \frac{\partial^2\sigma_2^{(i)}}{\partial T^2} - \frac{\partial^2\eta_i}{\partial T^2}\right) + (x_i - 1)\left(2\frac{\partial\gamma_i}{\partial T} + T\frac{\partial^2\gamma_i}{\partial T^2}\right)\right] \tag{8}$$

The coefficients of thermal expansion and of isothermal compressibility for the components 1 and 2 are deduced from the equations of definition

$$\alpha_i = \frac{(\partial V_i/\partial T)_P}{V_i} \tag{9}$$

$$\beta_{T_i} = -\frac{(\partial V_i/\partial P)_T}{V_i} \tag{10}$$

The derivatives occurring in the above relations are deduced from the pressure formula, i.e. from the state equation according to the significant structures theory. Starting from the formula $P = -(\partial F_i/\partial V_i)_T$ and taking into account that $x_i = V_i/V_{s_i}$, we obtain

$$P = \frac{RT}{V_{s_i} x_i^2}\left[-2(\sigma_1^{(i)} + \sigma_2^{(i)} - \eta_i) + 2x_i\left(\frac{\partial\sigma_1^{(i)}}{\partial x_i} + \frac{\partial\sigma_2^{(i)}}{\partial x_i}\right) + \gamma_i + \ln\frac{V_{s_i}}{N}\,x_i + x_i\right]. \tag{11}$$

According to whether i is equal to 1 or to 2, two expressions will be obtained, identical as to their form, one of which corresponding to component 1, used in the computations of this component, and another to component 2, necessary in the calculations of component 2. The derivative $(\partial V_i/\partial T)_P$ is calculated indirectly by the relation

$$\left(\frac{\partial V_i}{\partial T}\right)_P = -\left(\frac{\partial P}{\partial T}\right)_{V_i} \Big/ \left(\frac{\partial P}{\partial V_i}\right)_T \tag{12}$$

The previously presented relations, as well as the manner of deducing them, were given in the preceding paper, [1] where we computed the heat capacity, the thermal-expansion coefficient and the isothermal compressibility coefficient of the pure ionic liquids NaCl, NaBr, KCl, KBr. They were resumed here, on the one hand, so as to make unitary the present paper that deals with binary mixtures and, on the other hand, because some changes have intervened in the notations. The necessary parameters for these computations were equally given in the above mentioned paper. [1]

Following the general method for establishing the partition function of a binary system [3,4] we deduce the following expression [5] for the ionic liquids

$$\begin{aligned} Z_{12} = \Bigg\{ & \frac{(X_1+X_2)!}{X_1!\,X_2!} \left(\frac{\exp[(E_s/2RT)\,(V/V_s)^{1/3}}{[1-\exp(-\theta_1/T)]^3} \Bigg\{ 1 + n_h \exp \times \right. \\ & \left. \times \left[- \frac{aE_s\,(V/V_s)^{1/3}}{2n_h\,RT} \right] \Bigg\} \right)^{2X_1 \frac{V_s}{V}} \times \left[\frac{(2\pi\, m_1\, kT)^{3/2}}{h^3}\, \frac{8\pi^2 I_1 kT}{h^2} \times \right. \\ & \left. \times \frac{1}{1-\exp(-h\nu_1/kT)}\, \frac{eV}{N} \right]^{X_1 \frac{V-V_s}{V}} \times \\ & \times \left(\frac{\exp[(E_s/2\,RT)\,(V/V_s)^{1/3}}{[1-\exp(-\theta_2/T)]^3} \Bigg\{ 1 + n_h \exp\left[- \frac{a\,E_s\,(V/V_s)^{1/3}}{2n_h\,RT} \right] \Bigg\} \right)^{2X_2 \frac{V_s}{V}} \times \\ & \times \left[\frac{(2\pi\, m_2\, kT)^{3/2}}{h^3}\, \frac{8\,\pi^2 I_2\, kT}{h^2}\, \frac{1}{1-\exp(-h\nu_2/kT)}\, \frac{eV}{N} \right]^{X_2 \frac{V-V_s}{V}} \end{aligned} \tag{13}$$

where $n_h = n\,\dfrac{V-V_s}{V}$, while X_1 and X_2 are the molar-fractions of the two components.

The expression of the binary partition function contains the parameters of the two component liquids, as well as the characteristic parameters of the mixture. They are E_s, V_s, V, a and n. The volume V is calculated with density data of the mixture, while the other parameters are calculated with the aid of the following formula

---

[5] R. Vîlcu and C. Misdolea, *J. Chem. Phys.*, **45**, 3414 (1966).

$$E_s = (X_1 \sqrt{E_{s_1}} + X_2 \sqrt{E_{s_2}})^2$$

$$V_s = (X_1 \sqrt[3]{V_{s_1}} + X_2 \sqrt[3]{V_{s_2}})^3$$

$$a = X_1 a_1 + X_2 a_2$$

$$n = X_1 n_1 + X_2 n_2$$

From the partition function (13) we deduce the Helmholtz free energy of the binary system

$$F_{12} = - RT \ln Z_{12} = - RT \left[\ln \frac{(X_1 + X_2)!}{X_1 !\, X_2 !} + \frac{2}{x} (\sigma_1 + \sigma_2) - \right.$$

$$\left. - \frac{2}{x} (X_1 \eta_1 + X_2 \eta_2) + \left(1 - \frac{1}{x}\right) \left(X_1 \gamma_1 + X_2 \gamma_2 + \ln \frac{V_s}{N} x + 1\right)\right] \tag{14}$$

where $x = V/V_s$.

The following notations were adopted

$$\sigma_1 = \frac{E_s}{2RT} x^{1/3} \tag{15}$$

$$\sigma_2 = \ln \left[1 + n(x-1) \exp\left(- \frac{aE_s}{2n\,RT} \frac{x^{1/3}}{x-1}\right)\right] \tag{16}$$

Quantities σ_1 and σ_2 are characteristic of the mixtures while the other quantities γ_1, γ_2, η_1 and η_2 are characteristic of the components.

The heat capacity at constant volume is obtained by the same method as in the case of the components, from internal energy

$$U = RT^2 \left(\frac{\partial \ln Z_{12}}{\partial T}\right)_V$$

which has to be derived with regard to the temperature. We obtain

$$C_V = \frac{RT}{x}\left\{4\left[\frac{\partial\sigma_1}{\partial T}+\frac{\partial\sigma_2}{\partial T}-\left(X_1\frac{\partial\eta_1}{\partial T}+X_2\frac{\partial\eta_2}{\partial T}\right)\right]+\right.$$

$$+\,2T\left[\frac{\partial^2\sigma_1}{\partial T^2}+\frac{\partial^2\sigma_2}{\partial T^2}-\left(X_1\frac{\partial^2\eta_1}{\partial T^2}+X_2\frac{\partial^2\eta_2}{\partial T^2}\right)\right]+ \tag{17}$$

$$\left.+\,(x-1)\left[2\left(X_1\frac{\partial\gamma_1}{\partial T}+X_2\frac{\partial\gamma_2}{\partial T}\right)+T\left(X_1\frac{\partial^2\gamma_1}{\partial T^2}+X_2\frac{\partial^2\gamma_2}{\partial T^2}\right)\right]\right\}$$

The thermal-expansion coefficient and the isothermal compressibility are deduced from the following relations

$$\alpha = \frac{(\partial V/\partial T)\;P}{V} \tag{18}$$

$$\beta_T = -\,\frac{(\partial V/\partial P)_T}{V} \tag{19}$$

As in the case of the components, the derivatives from relations (18) and (19) shall be obtained by means of the pressure formula

$$P = -\,(\partial F_{12}/\partial V)_T = \frac{RT}{V_s\,x^2}\left[-\,2\,(\sigma_1+\sigma_2)+2x\left(\frac{\partial\sigma_1}{\partial x}+\frac{\partial\sigma_2}{\partial x}\right)+\right. \tag{20}$$

$$\left.+\,2\,(X_1\,\eta_1+X_2\,\eta_2)+(X_1\gamma_1+X_2\gamma_2)+\ln\frac{V_s}{N}\,x+x\right]$$

The derivative $(\partial V/\partial T)_P$ is obtained in the same way as (12)

$$\left(\frac{\partial V}{\partial T}\right)_P = -\left(\frac{\partial P}{\partial T}\right)_V \Bigg/ \left(\frac{\partial P}{\partial V}\right)_T \tag{21}$$

RESULTS

Computations were made for systems with a common cation K(Cl—Br) and Na(Cl—Br) as well as for the system with a common anion Cl(Na—K). In order to follow the variation with the temperature of the computed quantities, three temperatures were considered, namely 1073 K, 1173 K and 1273 K. The molar fractions, with which the computations were made, were determined with the aid of the data available for the densities.[6-8]

Formula (17) gave the heat capacities at a constant volume. For the Na(Cl—Br) system they are to be found in table 1. In this table, as in those for other systems, there are equal data concerning the components so as to make the comparations possible. No experimental data concerning C_v are available for the mixtures of ionic liquids. The heat capacities at constant volume are given in table 2 for the K(Cl—Br) system and in table 3 for the Cl(Na—K) system.

The thermal-expansion coefficient was computed with the aid of formulae (18) and (21). From the density variation with temperature, that is known for all three systems, [6–8] the experimental values of this coefficient can be deduced

$$\alpha = -\frac{1}{\rho}\left(\frac{\partial \rho}{\partial T}\right)_P$$

The excess thermal-expansion coefficient was computed with formula

$$\alpha^E = \alpha - (\ \Phi_1\alpha_1 + \ \Phi_2\alpha_2)$$

where Φ_1 and Φ_2 indicate the volumetric fractions of the two components The results are to be found in tables 4, 5, and 6.

No experimental data are available for the isothermal compressibility. The speed of the ultrasounds in the component liquids as well as in their binary mixtures allows to compute the adiabatic compressibility.[10,11] The theoretical data concerning this coefficient are computed with the formula

$$\beta_s = \frac{\beta_T}{\gamma} \tag{22}$$

where $\gamma = C_p/C_v$, while for C_p we have the relation

$$C_p = C_v + \frac{\alpha^2 VT}{\beta_T} \tag{23}$$

The excess adiabatic compressibility is

$$\beta_s^E = \beta_s - (\Phi_1 \beta_{s_1} + \Phi_2 \beta_{s_2})$$

The results concerning K(Cl—Br) and Cl(Na—K) systems are registered in tables 7 and 8.

No experimental data concerning the Na(Cl—Br) system are available for β_T nor for β_s. The theoretical results are registered in table 9.

DISCUSSIONS

The examination of the computation results for the heat capacities at constant volume shows that the significant structures theory leads to results in good concordance with the experimental data. The variation

with temperature is also correctly represented : the computations show, moreover, a diminution with the temperature as is also observed experimentally. In all three systems, however, at all temperatures, the computed C_v increases for the component for which the experimental data indicate a diminution. No experimental data of the heat capacities are yet available for the binary systems of ionic liquids. The thermal expansion coefficient does not offer such a good concordance as that of the heat capacities, particularly at 1073 K temperature. It is though satisfactory, especially at higher temperature; so, at 1273 K, the concordance is good and sometimes even quite good. But this good concordance is due to the fact that the initial computed values, higher than the experimental ones, diminish with temperature, while the experimental values increase with temperature, so that at 1273 K they are near enough to one another. For α^E, the concordance is no more good even at 1273 K. But in this case, the magnitude order being 10^{-6} against 10^{-4} for α, the experimental values can be strongly influenced by the errors appearing at the determination of the density. Isothermal as well as adiabatic compressibility show a distinct non-concordance with the experimental data. For the isothermal compressibility, the computed data are hardly higher

than the half of the experimental data, while for the adiabatic compressibility, the non-concordance is still greater. The variation with temperature is however correctly represented. The computed data indicate an increase with the temperature and the experimental ones confirm it. In the computation of the heat capacity at constant volume, only the derivatives of the various parts of the partition function with regard to the temperature appear. The good concordance between the theoretical data and the experimental ones indicate that the intervention of the temperature in the expression of the partition function is correct. The disagreement between the theoretical values of the isothermal and adiabatic compressibility – in the expressions of which appears the derivative of the partition function with regard to the volume – and the experimental values, shows that the partition function has no formulation able to reflect correctly enough the structure of the liquid.

INFLUENCE OF ALKALINE CATIONS ON THE SENSITIVITY OF THE PHOTOTROPIC GLASSES WITH AgCl

P. BALTĂ * and L. DOLLINGHER **

* Polytechnic Institute, Str. Polizu 1, Bucharest
** Centre of Physical Chemistry, Str. Galaţi 31, Bucharest, Romania

Received September 2, 1972

Continuing the previous investigations, phototropic glasses on B_2O_3 basis have been studied, to which small quantities of alkaline oxides were added. It was established that the sensitivity of the simple phototropic glasses changes inversely proportional with the coordination number of the alkaline cation met in the composition. The phenomenon has been correlated with the influence of the alkaline cations on the separation process of the vitrous microphases. The study of the X-ray fluorescence of silver confirms the hypothesis presented in one of our previous papers, according to which silver chloride and complexes including boron and alkaline cation are met in these glasses under the form of metallic silver.

1. INTRODUCTION

In one of our previous works [1] we have revealed the possibility of outlining the specific influence of the cation in a phototropic glass with maximum simplified composition, when introduced together with the network formator and silver chloride, having in view the possibility of obtaining new data in connection with the mechanism of the process that takes place in the phototropic glasses with AgCl.

We report hereby a new series of results obtained on the same simple B_2O_3 glass following the investigations carried on in this field.

2. EXPERIMENTAL

We have synthetized phototropic glasses having compositions presented in table 1. The mixture of raw material was melted and maintained at 850° for one hour. After that, plates with a thickness of 2 mm have been obtained. The glasses were thermically treated at 250°, 275° and 300° for 15, 30 and 60 minutes to lend them phototropic properties.

---

[1] P. Baltă, L. Dollingher and M. Cîrstea, *Rev. Roumaine Chim.*, **17**, 25 (1972).

Transmission measurements were performed on these samples, in the same way as reported in our previous papers, [2,3] depending on the duration of ultraviolet irradiation, also recording the X-ray fluorescence spectra of silver.

Table 1

Synthesized glasses of (% molar) composition: M_2O = 2.28%; AgCl = 0.675%; B_2O_3 = 97.045%

Composition of raw material mixture (g)	Glass

B_2O_3	—	98	95.59	93.28	90.14
$AgNO_3$	1.7	1.66	1.62	1.59	1.53
HCl (conc)	10 cc	—	—	—	—
NaCl	—	3.82	—	—	—
KCl	—	—	4.81	—	—
RbCl	—	—	—	7.66	—
CsCl	—	—	—	—	9.64

3. RESULTS AND DISCUSSIONS

As the sensitivity of these glasses to ultraviolet radiations, as well as the thermal fading rate, are influenced by previous thermal treatments, as can be seen in figure 1 for the case of glass containing Na_2O, all samples were submitted to the same thermal treatment: 30 minutes at 275°.

The measurement results of the transmission changes, depending on the duration of the ultraviolet irradiation of constant intensity, are presented in figure 2.

An order of the obtained curves according to the alkaline cation contained is noticed. The most sensitive is the glass not containing alkaline cations (glass 19, table 1) but which, owing to the mixture of raw materials and to the melting conditions, contains hydrogen. After 420 seconds of irradiation, the transmission of this glass decreases to about 42%, as compared with the initial one considered 100%. The cesium glass has the lowest sensitivity, its transmission decreasing to about 70%, after the same period of irradiation.

A very interesting fact, namely that the variation of the equilibrium transmission (after 420 seconds of irradiation) is directly proportional to the coordination number of the contained cations is presented in figure 3.

The sensitivity of the respective glass decreases depending on the increase of the coordination number. This correlation suggests the idea that the sensitivity decrease could be determined by a separation tendency

[3] P. BALTĂ and E. BALTĂ, "Introducere în chimia fizică a stării vitroase", Ed. Acad., București, 1971.

of the vitrous microphases. Concurrently with the rise of the coordination number, it is possible that the Cl⁻ ion contained in the alkaline chloride should be kept to a greater extent in the coordination sphere of the respective cation, and, consequently, the silver halide should hardly separate as big enough grains.

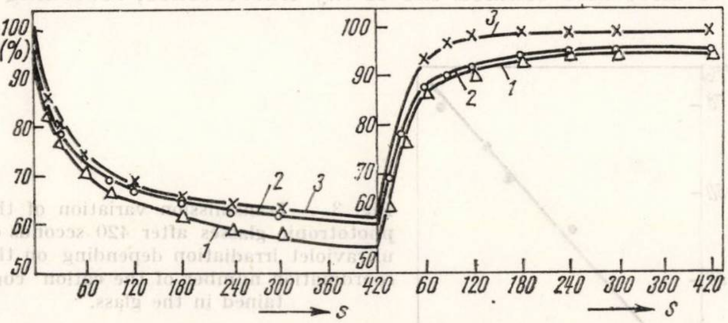

Fig. 1. — Colouring curves at irradiation with UV rays (a) and fading when heating at 200° (b) of phototropic glass No. 20 (Table 1) containing Na⁺ ions, thermically treated before irradiation, in the following conditions :
1) 15 min at 275°; 2) 30 min at 275°; 3) 60 min at 275°.

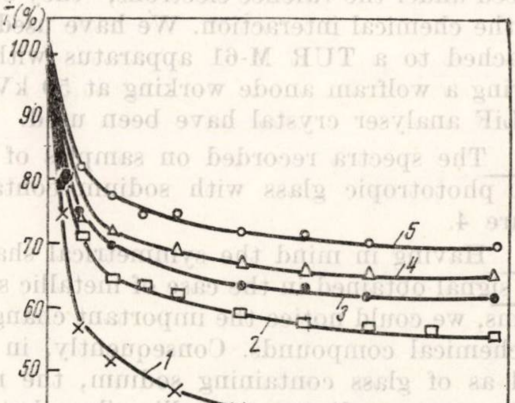

Fig. 2. — Transmission variation of the phototropic glass samples with different cations, when irradiated with ultraviolet rays :
1) glass 19; 2) glass 20; 3) glass 15; 4) glass 16; 5) glass 17, from Table 1.

Taking into account the fact that the number of alkaline cations is the same for all glasses, it is natural that this tendency should grow concurrently with the coordination number.

As a matter of fact it is known that the separation tendency of the vitrous microphases decreases from the glasses containing Na_2O to those containing K_2O, Rb_2O and Cs_2O. If the electromicroscopical pictures confirm this theory, it will allow to prove scientifically the mechanism by which the network modifier cations affect the properties of the phototropic glasses containing AgCl.

For obtaining information regarding the existence of silver in these glasses, we have also studied the X-ray fluorescence, recording the $K_3\beta_2$ peak of silver from $\lambda = 1458$ Å representing the behaviour of the electrons placed under the valence electrons,[4] they being strongly enough influenced by the chemical interaction. We have used a HZG 1 RFA 1 spectrometer attached to a TUR M-61 apparatus with a FS 35 Ö fluorescence tube having a wolfram anode working at 50 kV tension and 20 mA intensity. A LiF analyser crystal have been used.

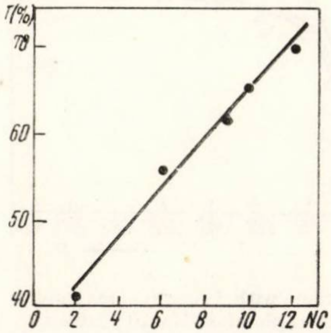

Fig. 3. — Transmission variation of the phototropic glasses after 420 seconds of ultraviolet irradiation depending on the coordination number of the cation contained in the glass.

The spectra recorded on samples of metallic silver, silver chloride and phototropic glass with sodium containing silver are presented in figure 4.

Having in mind the symmetrical shape and the high amplitude of the signal obtained in the case of metallic silver, not influenced by foreign atoms, we could notice the important changes appeared in silver occurring in chemical compounds. Consequently, in the case of silver chloride as well as of glass containing sodium, the maximum of 21°15′ is noticed again corresponding to metallic silver but it is also noticed a widening of the band to the angles with higher values.

Ligand field greatly influences the properties of the transitional ions.

The fluorescence emission is therefore expected to differ from that of the pure metal in case of Ag^+ ion surrounded by Cl^- ions. Consequently, the second emission maximum of AgCl occurred at 21°30′ can be supposed to correspond to silver bound as AgCl. The occurrence of metallic silver in AgCl is not suprising, taking into account the fact that it decomposes easily in the presence of light, and it has been exposed to X-rays during the experimental.

---

[4] K. SAGEL, "Tabellen zur Röntgen Emision und Absorbtion Analyse", Springer Verlag, Berlin, 1959.

In the spectrum recorded on the phototropic glass we could notice a prominent peak corresponding to metallic silver, a lower peak in the position of AgCl and a third one at 21°45′ that could be assigned to Ag partially or totally surrounded by oxygen ions, namely occurred under the form of silver borate or as sodium and silver borate or chloroborate, as reported in one of our previous papers.[1]

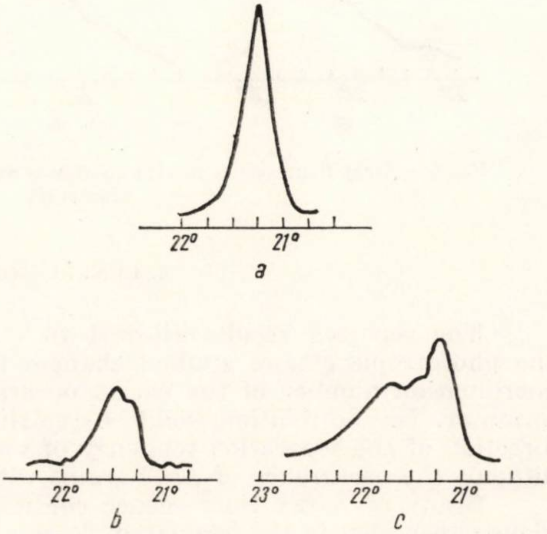

Fig. 4. — Line $K_3\beta_2$ met in the X-ray fluorescence spectrum of metallic silver (a), of silver contained in silver chloride (b), and in the phototropic glass with-sodium(c).

The widening of this band exceeding 22° seems to confirm the presence of a series of complexes in which the ligand properties influenced by boron and sodium change to a sufficient extent for justifying the widening of the emitted band.

It can be noticed the fact that the direction of the ligand field influence is the same as in the case of charge transfer.[3]

The intensity rise of the ligand field from chlorine to oxygen brings about a shifting of the emission maximum to lower energies.

The presence in the second coordination sphere of alkaline ions (in the case of complexes) brings about a new rise of the ligand field because of a rise of their polarizability and, consequently, the widening of the emitted band to longer wavelengths.

In figure 5 it is ascertained that the general aspect of the recorded spectra remains the same in the case of all glasses containing alkaline ions. It is nevertheless noticed a general decrease of intensity from the glass containing sodium to that with cesium.

It is possible that this effect should be correlated with the decrease of the concentration of fluorescence centres because of silver dispersion, that, as we have previously reported, increases in the same direction.

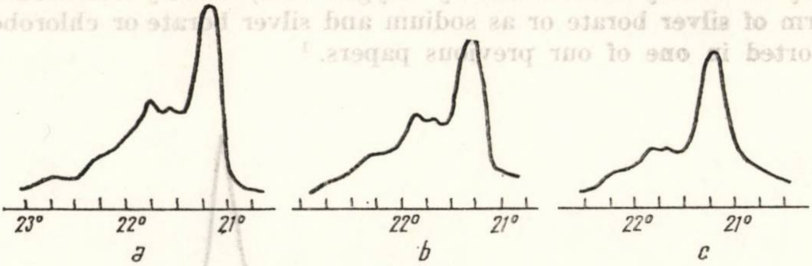

Fig. 5. — X-ray fluorescence spectra on glasses with sodium (a), potassium (b), and cesium (c).

4. CONCLUSIONS

The reported results allowed to establish that the sensitivity of the phototropic glasses studied changes inversely proportional with the coordination number of the cation occurring together with the network formator. This correlation could be explained by the decrease in the same direction of the separation tendency of vitrous microphases, making more difficult the occurrence of AgCl grains with big enough dimensions.

Study of X-ray fluorescence confirms the idea, reported in a previous paper, that in the irradiated glasses, silver occurs, from the chemical point of view, in three states : as metallic silver, silver chloride and under the form of complexes as silver borates or chloroborates, or double borates of silver and sodium.

The above data represent a contribution to a more profound and accurate understanding of the phototropic glasses structure and of the mechanism of the occurring processes.

NEW COMPOUNDS OF YTTRIUM AND LANTHANIDES WITH DERIVATIVES OF ANTHRANILIC ACID. I

THE N,N BIS (CARBOXY METHYL) ANTHRANILIC ACID (ANDA)

P. SPACU and EUGENIA IVAN

Research Center of Physical Chemistry
Str. Dumbrava Roşie, 23, Bucharest, Romania

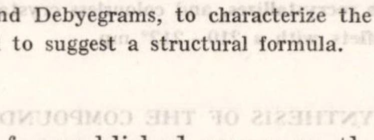
Received October 2, 1972

New compounds of yttrium and lanthanides were synthetized with N,N bis (carboxy methyl) anthranilic acid (ANDA) having the general formula : [Ln ANDA] · $3H_2O$; Ln = La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Yb and Y. They are also chemically characterized by electronic spectra in ultraviolet and visible ranges, IR spectra and Debyegrams, to characterize the chemical bonding of these compounds and to suggest a structural formula.

There are rather few published papers on the synthesis of the compounds with carboxy methyl derivatives of anthranilic acid.

Young *et al*[1] giving a series of values for the stability of the complexes of bivalent metals with anthranilic acid and its derivatives, shows the attaching effect of acetic groups to amino nitrogen on the stability, as reflected in the sequence : anthranilic acid < anthranilic monochloroacetic acid < anthranilic diacetic acid. This may be due to the fact that the number of chelate rings increases as the carboxy methyl groups are introduced step by step to anthranilic acid.

The N,N bis (carboxy methyl) anthranilic acid (ANDA) belongs to the class of complexons derivated from monoamine, having a betainic structure in solution :



(1)

---

[1] A. Young and T. R. Sweet, *J. Am. Chem. Soc.*, **80**, 800 (1958).

According to the kind of metallic ions, ANDA may behave as a tridentate ligand, as well as a quadridentate one. [2-8]

In the present paper we have studied the compounds formed by ANDA with trivalent ions of yttrium and lanthanides.

A compound of lanthanum with ANDA corresponding to the formula : La ANDA.4 H_2O was isolated from 95% Et OH, [4] but appears as a very hygroscopic compound.

EXPERIMENTAL

MATERIALS

The chlorides and nitrates of yttrium and the lanthanides were obtained from the respective oxides Johnson-Mathey of 99.9% purity, excepting Eu_2O_3 — of 98% purity, by processing with diluted 1 : 1 chlorhydric acids, respectively nitric acid, Merck.

The N,N bis (carboxy methyl) anthranilic acid or anthranil diacetic acid (ANDA), $C_{11}H_{11}NO_6$, was synthetized making use of the directives found in literature [1,8] in the following way : the mixture of anthranilic and monochloracetic acids, in a 1 : 3 ratio is passed into a neutral solution of NaOH—2n and anhydrous Na_2CO_3 is refluxed for 3 hours, continuously correcting the pH at 7. By acidulation and boiling with HCl (at pH = 2) it precipitates the anthranil diacetic acid, which recrystallizes, and colourless crystalls are obtained in the form of unfluorescent brilliant leaflets with a 210—212° mp.

SYNTHESIS OF THE COMPOUNDS

The lanthanide compounds with ANDA were obtained in two ways :

1) To a solution (0.04 M) lanthanide or yttrium chloride 50 ml with a pH = 4.5—5.5 (according to the lanthanide) is added 50 ml of the reactive obtained in the following way : 5 g of ANDA are dissolved in NH_4OH—2n, and heated to remove the excess of ammonia. The solution is filtered, 20 ml of ethanol are added and one completes with water in a calibrated flask of 500 ml (pH = 4.5). The pH of the solutions mixture falls to 3, and the precipitation takes place in time. The alcohol favours the apparition and agglomeration of the precipitate, but the precipitates obtained are gelatinous and the yield in the compound is low.

2) 0.5 g of ANDA are solved (heated) in 25 ml of water (pH = 2) and the lanthanide chloride solution is added (0.3 g $LnCl_3$ aq in 25 ml water). The ratio ANDA : Ln = 1 : 1. After 15 minutes of heating on a water bath, by stirring there appears a crystalline precipitate which during one hour is enriched and deposited.

[5] C. Drăgulescu, R. Pomoje and I. Menessy, "Omagiu Raluca Ripan", 225 (1966).

[6] C. Drăgulescu, S. Policec and T. Simonescu, *Talanta*, **13**, 1451, 1543 (1966); **17**, 557 (1970).

[7] C. Drăgulescu, I. Menessy, M. Pîrlea and A. Ferencz, *Bull. Soc. Chim. Fr.* **(1967)**,4740.

[8] C. Drăgulescu, R. Pomoje, I. Menessy and M. Pîrlea, *Rev. Roumaine Chim.*, **15**, 1029, 1543 (1970).

If the ANDA solution is neutralized at pH = 6 – 7 with NH_4OH-2n, the precipitation takes place immediately and quantitatively. The deposited precipitate is filtered, washed with warm water and then with anhydrous ethanol to remove the unreacted ANDA excess.

The substances are dried in free air, at room temperature.

The whole series of compounds with yttrium and the following lanthanides : La, Ce, Pr, Sm, Eu, Gd, Tb, Dy, Ho, Er, Yb were obtained by the second method ; correcting the pH with NH_4OH-2n.

CHEMICAL ANALYSIS

The lanthanide was determined by direct combustion at the respective oxide. N, C, H were determined by microanalysis.

The absorption spectra in ultraviolet for ANDA were carried out for the 10^{-4} M methanol and dioxan solutions (pH = 4) and for aqueous 2.10^{-3} M solutions with pH : 4.5 , 8.2 and 9.3 (in the presence of NH_4OH).

The reflexion spectrum ($\lambda = 250-400$ mm) was measured for the solid ligand in 1 : 4 and 1 : 5 dilutions with MgO.

For all the synthetized compounds we have only measured the reflexion spectra in ultraviolet, in 1 : 5 dilution, and in visible range ($\lambda = 360-1100$ mm) on the substance itself, using MgO for reference.

The reflexion spectra of Pr, Nd, Dy, Ho and Er nitrates were also determined, considered as reference aquo ions.

The measurements on solutions were carried out at a spectrophotometer Carl Zeiss VSU-2 and those on tablets on a spectrophotometer Carl Zeiss VSU-1, having the reflexion device attached.

IR spectra were achieved at a UR-10 spectrophotometer on KBr, tablets in the 400–4000 cm^{-1} field for ANDA and the compound of neodymium with water [Nd ANDA].3 H_2O and without water (heated to 230° – the minimal point on the curve DTA).

The X rays diffraction spectra were achieved at a TUR M-60 apparatus for ANDA and all the compounds by the method of Debye-Scherrer powders. The following radiations were used according to the absorption of lanthanides.

Table 1

Selection of X diffraction conditions for lanthanides

Lanthanide	Radiation	[A°]	Filter
La, Ce, Pr, Nd	Cr K_{α_1}	2.28962	V
Sm	Fe K_{α_1}	1.93597	Mn
Eu, Gd	Co K_{α_1}	1.78892	Fe
Tb, Dy	Ni K_{α_1}	1.65784	Co
Y, Ho, Er, Yb	Cu K_{α_1}*	1.54051	Ni

* Radiation CuK_{α_1} was used for ANDA.

The recording of the films was carried out at a Carl Zeiss microphotometer with a recorder.

For ANDA and the compounds Y, Er and Yb the diffraction spectra were also recorded at a diffractometer HZG-1 (RDG) using the radiation $CuK_{\alpha 1}$.

The conversion of the θ angles into d [A°] was made by means of the tables of A. J. Rose.

RESULTS AND DISCUSSIONS

The results of the chemical analysis are given in table 2.

Table 2

Analytical data

Found	La = 31.85 %	C = 29.69 %	H = 3.60 %	N = 3.17 %

Calculated $YC_{11}H_8NO_6.3H_2O$	Y = 22.61 %	C = 33.61 %	H = 3.59 %	N = 3.56 %

Based on the chemical data it was established that the chemical formula for the synthetized compounds corresponds to the ratio 1:1 Ln/ANDA with $3H_2O$($C_{11}H_8O_6N$ Ln.$3H_2O$). Only in the case of the lanthan compound, synthetized by the first method there is the chemical formula La ANDA.$4H_2O$.

Found: La = 30.60; C = 28.60; H = 3.90%, N = 3.09%

Calculated for $LaC_{11}H_8O_6N$ La = 30.12; C = 28.65; H = 3.49% N = 3.04%.

The compounds obtained are not hygroscopic, are stable in time, and do not melt up to 250—280°.

Regarding the colour, this is in the shade of lanthanides, respectively: white for Y, La, Eu, Gd, Tb, Dy and Yb; cream for Ce, Sm, Ho; light green for Pr; light lavender for Nd and pink for Er.

The solubility of the compounds obtained is very low, less than 10^{-3} M, in the majority of organic solvents. This fact has limited the spectrophotometric study only to measurements on solid substance.

The reflexion spectra of the ligand and their synthetized compounds present 2 maxima each in ultraviolet at:

$\lambda_1 = 355 - 365$ nm
$\lambda_2 = 265 - 268$ nm for ANDA

and

$\lambda_1 = 302 - 306$ nm
$\lambda_2 = 255 - 258$ nm for [Ln ANDA].$3H_2O$

In figure 1 are represented the reflexion spectra in ultraviolet, in 1 : 5 dilution with MgO for ANDA and compounds with Y, La and Ce. The other compounds with lanthanides present similar spectra and the plotting of all the curves on the same figure was impossible.

In the absorption spectra of the ligand in methanol or dioxan, absorption bands are not precisely outlined, and among the absorption spectra in aqueous solutions at different pH 4.5, 8.2, 9.3, figure 1 represents (the dotted line) the spectrum presenting the band at 302 nm.

Between the reflexion spectrum of the ligand and the compounds one notices a difference of 50 nm at the λ_1 band. The band at 302—306 nm appears only in the absorption spectrum of the ligand in solutions with pH > 7. This was interpreted [4] as the possibility of a betanic structure, in which the nitrogen becomes tetracoordinated.

The presence of this band also in the spectra of the studied compounds, is an indication that in the compounds, the nitrogen is tetracoordinated by coordination to the lanthanid ion, and ANDA can then behave as a quadridentate ligand. This fact is fully confirmed by the IR spectra.

In the reflexion spectra in visible range ($\lambda = 360-1100$ nm) shifts were located for certain bands of the compounds with Pr, Nd, Dy, Ho and Er, given the respective aquo ions, towards higher wave lengths.

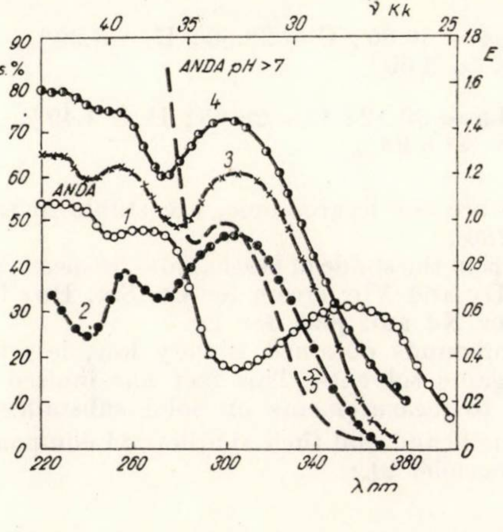

Fig. 1. — Reflexion spectra in ultraviolet in 1/5 dilution with MgO for : *1.* ANDA ; *2.* [Y ANDA]$.3H_2O$; *3.* [La ANDA]$.3H_2O$; *4.* [Ce ANDA]$.3H_2O$ and absorption spectra for *5.* ANDA in aqueous solution, with a pH = 9.3.

From these shifts, the average covalence degrees of the chemical bond were calculated, according to the formula [9] :

$$\delta' = \frac{1-\beta'}{\beta'} . 100 \text{ where}$$

β' = nephelauxetic ratio, and is given by the ratios :

$\beta' = \frac{\beta_{\text{complex}}}{\beta_{\text{aquoion}}} = \frac{\tilde{\nu}_{\text{complex}}}{\tilde{\nu}_{\text{aquoion}}}$ where $\tilde{\nu}_c$ and $\tilde{\nu}_{aq}$ are the wave numbers of the same transitions in the complex and respectively in the aquo ion.

As may be noticed from tables 3—7, the parameter δ′ takes still higher positive values in the case of compounds with Pr and Nd and positive values, but smaller, and even equal to zero for compounds with Dy, Ho and Er. This shows a more marked covalence of the chemical bond in the compounds having for central ion the lanthanide with f^2 (Pr) and f^3 (Nd) then the respective aquo ions, and this covalence decreases, becoming smaller, or even equal for those compounds in which the lanthanide ion has the lager f more completely occupied with electrons.

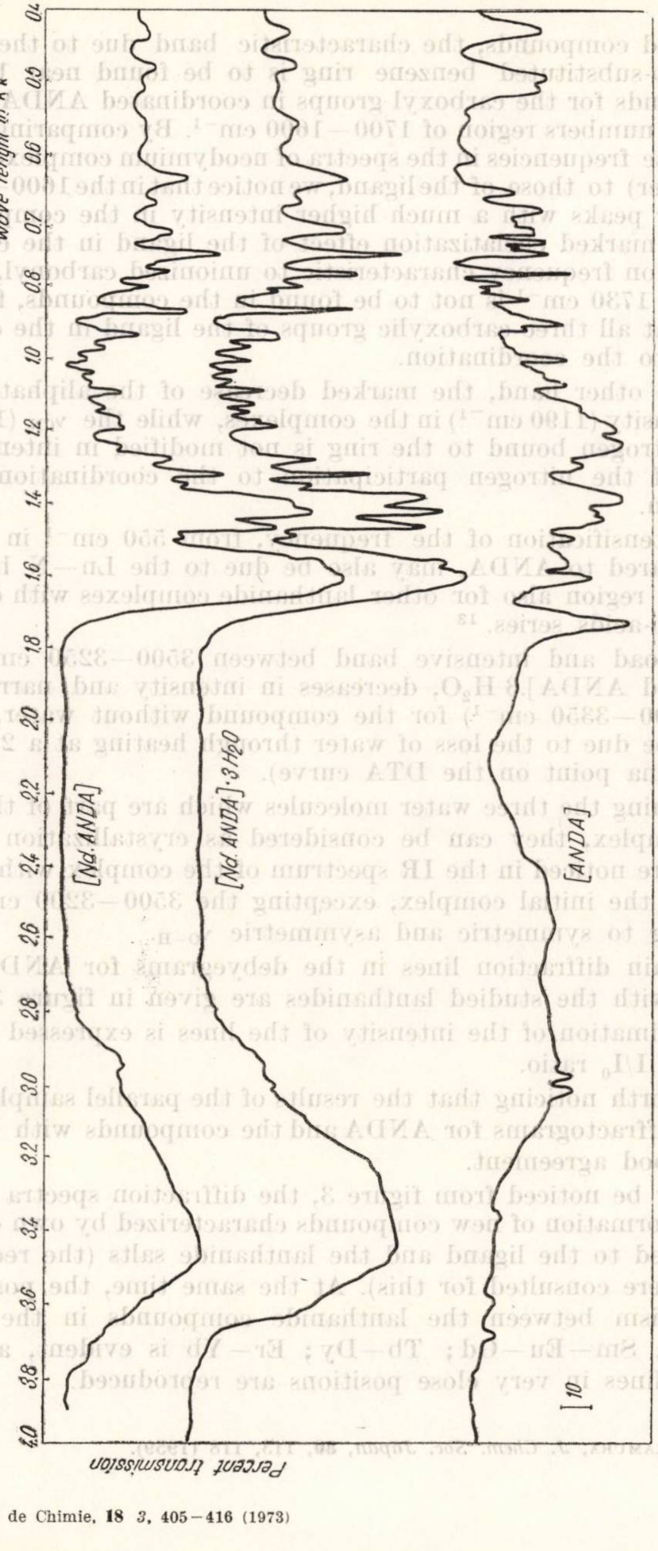

Fig. 2.— IR spectra for ANDA and compounds [Nd ANDA].$3H_2O$ and [Nd ANDA].

In all studied compounds, the characteristic band due to the stretching $\nu_{C=C}$ in *ortho*-substituted benzene ring is to be found near 1600 cm^{-1}, while the bands for the carboxyl groups in coordinated ANDA are shown within wave numbers region of 1700—1600 cm^{-1}. By comparing the intensities of these frequencies in the spectra of neodymium complexes (with, or without water) to those of the ligand, we notice that in the 1600–1700 cm^{-1} there appear peaks with a much higher intensity in the complexes, thus proving the marked chelatization effect of the ligand in the compounds. The absorption frequency characteristic to unionized carbonyl, appearing in ANDA at 1730 cm^{-1} is not to be found in the compounds, from where it results that all three carboxylic groups of the ligand in the compounds participate to the coordination.

On the other hand, the marked decrease of the aliphatic ν_{CN} frequency intensity (1190 cm^{-1}) in the complexes, while the ν_{CN} (1380—1375 cm^{-1}) for nitrogen bound to the ring is not modified in intensity, is an indication of the nitrogen participation to the coordination with the lanthanid ion.

The intensification of the frequency, from 550 cm^{-1} in the complexes compared to ANDA, may also be due to the Ln—N bond, identified in this region also for other lanthanide complexes with derivatives of the amino-acids series. [13]

The broad and intensive band between 3500—3250 cm^{-1} of the spectrum [Nd ANDA].3 H_2O, decreases in intensity and narrows down its field (3500—3350 cm^{-1}) for the compound without water, an effect which may be due to the loss of water through heating at a 230° temperature (minima point on the DTA curve).

Concerning the three water molecules which are part of the initially prepared complex, they can be considered as crystallization water, as no changes are noticed in the IR spectrum of the complex without water, compared to the initial complex, excepting the 3500—3200 cm^{-1} region corresponding to symmetric and asymmetric ν_{O-H}.

The main diffraction lines in the debyegrams for ANDA and its compounds with the studied lanthanides are given in figure 3.

The estimation of the intensity of the lines is expressed in percentages by the I/I_0 ratio.

It is worth noticing that the results of the parallel samples, debyegrams and diffractograms for ANDA and the compounds with Y, Er and Yb are in good agreement.

As may be noticed from figure 3, the diffraction spectra of X rays confirm the formation of new compounds characterized by own diffraction lines compared to the ligand and the lanthanide salts (the record cards of JCPDS were consulted for this). At the same time, the possibility of an isomorphism between the lanthanide compounds in the sequence Ce—Pr—Nd; Sm—Eu—Gd; Tb—Dy; Er—Yb is evident, as a series of intensive lines in very close positions are reproduced.

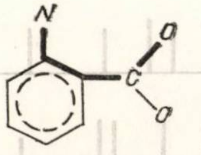
DISCUSSIONS ON THE STRUCTURE

As it results from electronic spectra in ultraviolet and the IR spectra, ANDA behaves, in the compounds obtained with Y and lanthanides, as a tetracoordinated ligand, using all four terminal atoms of its molecule, which can act as donors of a pair of electrons, namely: 3 oxygen atoms of the carboxyl group, 2 aliphatic groups and one aromatic plus a tertiary aminic nitrogen atom.

A convenient resonance interaction among the three carboxyls and the tertiary nitrogen atom through the benzene ring, may result in the shortening of the bond distances (shown by the thickened lines — formula 2) with a certain extrastabilization energy, and hence a higher chelating of the compounds may be achieved.[14]



(2)

The calorimetric and the ΔH and ΔS values[15] equilibrium measurements of the reaction the imino diacetic acids derivated from carboxyphenyl (H_3A) and carboxyethyl (H_3B) and alkaline-earth bivalent metals, have shown the possibility in the change of the character of the metal-nitrogen bond, connected to the presence or absence of a mesomeric interaction between the nitrogen and the benzenic nucleus in the case of the chelates of the ligand A^{3-}.

It is thus to be expected that ANDA should always behave as a quadridentate ligand.

Consequently, based on all the data obtained by the physico-chemical methods used, the following structural formula is possible for the compounds studied in the present paper:

KINETICS AND MECHANISM OF SUBSTITUTION REACTIONS OF COMPLEXES. XLIII*

BASIC HYDROLYSIS OF $[Co(DH)_2(H_2O)(NCS)]$

Z. FINTA, CS. VÁRHELYI and J. ZSAKÓ

Faculty of Chemistry, Chair of Physical Chemistry, Babeş-Bolyai University,
str. Arany János 11, Cluj, Romania

Received August 2, 1972

Synthesis and IR spectrum of $[Co(DH)_2(H_2O)(NCS)] \cdot 2\ H_2O$ are described. In basic solutions a protolytic equilibrium takes place. The acid form undergoes an aquation with $\Delta H_1^{\neq} = 32.4$ *k*cal/mole, presumably by an S_N1 pathway. The basic form participates to an olation reaction with $\Delta H_2^{\neq} = 22.5$ *k*cal/mole presumably on an $S_N^{\neq}2$ pathway. Results are compared with those obtained with the analogous dinitro- and nitro-aquo derivatives.

The aquo-acido-bis-dioximato-cobalt (III) non electrolytic complexes are formed as intermediates during the aquation of $(Co\ (Diox.H)_2X_2]^-$ type complex anions in acid solutions (where Diox. H_2 stands for a molecule of an α-dione-dioxime). Thus, aquation of $(Co\ (DH)_2\ Cl_2]^-$, $[Co(DH)_2Br_2]^-$, $Co(DH)_2I_2]^-$ (DH_2 = dimethylglyoxime) in dilute solutions leads in the first stage to the formation of $(Co(DH)_2(H_2O)Cl]$, $[Co(DH)_2(H_2O)Br]$ and $[Co(DH)_2(H_2O)I]$, respectively. [1–4] These compounds are known also in crystalline state, obtained by heating of aqueous suspensions of the $H[Co(DH)_2X_2]$ type complex acids. [5–6]

Some of the sparingly soluble halogeno-aquo-non-electrolytes are formed as the main product of the oxydation of a mixture of CoX_2, NaX and Diox. H_2, e.g. the following complexes : [Co(Niox. $H)_2(H_2O)Cl]$,[Co(Niox. $H)_2(H_2O)Br]$, [Co(Niox. $H)_2(H_2O)I]$. [7] (Niox. H_2 = cyclohexane diondioxime).

The analogous α-benzyldioximato derivatives [Co (Diph. H)$_2$–(H$_2$O)Cl], [Co(Diph. H)$_2$(H$_2$O)Br] which are also very sparingly soluble, have been obtained from [Co(Diph. H)$_2$Cl$_2$]$^-$ and [Co(Diph. H)$_2$Br$_2$]$^-$, by treating them with water.[8]

In the case of the [Co(DH)$_2$(H$_2$O)(NCS)] and [Co(DH)$_2$(H$_2$O)(NCSe)] type derivatives of the pseudohalogens, treatment with ammonia of the corresponding bis-dioximato-diacido complexes is necessary.

Thus the above mentioned thiocyanato-non-electrolyte has been obtained by Ablov and co-workers by means of aquation of [Co(DH)$_2$(NO$_2$)(NCS)]$^-$ in dilute ammoniacal solution.[9]

In the present paper [Co(DH)$_2$(H$_2$O)(NCS)]·2 H$_2$O has been synthesized as described in the experimental part. IR spectrum of the complex obtained is given in fig. 1.

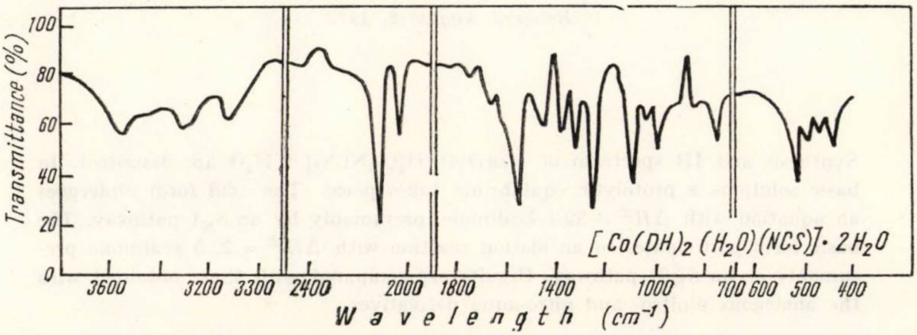

Fig. 1. – IR spectrum of [Co(DH)$_2$(H$_2$O)(NCS)]·2 H$_2$O.

The weak bands characteristic for the short O–H...O hydrogen bridges, observed in the case of [Co(DH)$_2$(amine)$_2$]X[10] and H[Co(DH)$_2$X$_2$][11] type complexes, too, appear at 2360 cm^{-1} (weak) and at 1720–1740 cm^{-1} (weak). These bands plead also in this case for a *trans* geometric configuration. The stretching vibration frequencies $\nu_{C=N}$ and ν_{C-S} characteristic for the coordinated NCS group appear at 2114 (very strong) and 820–830 cm^{-1} (medium), respectively. Their position and intensity is almost the same as in the case of [Co(DH)$_2$(NCS)$_2$]$^-$, i.e. the complex studied is also an isothiocyanato derivative, NCS is linked to Co through the N atom,[11–13] contrary to the thiocyanato complexes of Pt, Pd and Hg.

In acid solutions of [Co(DH)$_2$(H$_2$O)(NCS)] no aquation reaction occurs. In the case of the [Co(DH)$_2$(NCS)$_2$]$^-$ ion only the first NCS$^-$ can be exchanged for water molecules. Even this reaction affords a considerably high activation enthalpy of 32.2 Kcal/mole and leads to an equilibrium shifted towards the dithiocyanatocomplex. The equilibrium constant of reaction

$$[Co(DH)_2(NCS)_2]^- + H_2O \rightleftarrows [Co(DH)_2(H_2O)(NCS)] + NCS^- \quad (1)$$

is of the order of magnitude of 10^{-5}. [14]

In basic solutions the situation may be fundamentally changed. The aquo-non-electrolytic type complexes $[Co(DH)_2(H_2O)X]$ show the behaviour of weak acids with an acidity constant of about 10^{-7}—10^{-8}. [15-17]

In basic solutions, due to the equilibrium

$$[Co(DH)_2(H_2O)(NCS)] \rightleftarrows [Co(DH)_2(OH)(NCS)]^- + H^+ \quad (2)$$

a complex anion, similar to $[Co(DH)_2(NCS)_2]^-$, appears, which may suffer an aquation. On the other hand, in strongly basic media another protolytic equilibrium takes place, implying the break up of a O—H..O hydrogen bridge, [18] the corresponding acidity constant being of the order of magnitude of 10^{-12}. [16 19]

Presumably, the equilibrium :

$$[Co(DH)_2(OH)(NCS)]^- \rightleftarrows [Co(DH)(D)(OH)(NCS)]^{-2} + H^+ \quad (3)$$

makes easier the liberation of NCS^- ions.

On the basis of the above considerations one can expect the aquation of the complex studied to take place with a measurable rate. Our experiments were consistent with this presumption. By measuring the concentration of the liberated NCS^- ions as function of time, OH^- concentration and temperature, reaction has been observed to be apparently of first order. Logarithmic plot of c_0/c versus time showed a good linearity, as seen from several examples given in fig. 2.

From the slope of the straight lines obtained, apparent first order rate constants k_{exp} have been derived. Results are presented in table 1.

Influence of OH^- concentration on k_{exp} values is completely different from that observed in the case of $[Co(DH)_2(H_2O)(NO_2)]$, where a protolytic equilibrium of the type (3) and the aquation of both forms have been observed. [17] Rate constants k_{exp} presented in table 1 show a nearly linear increase at higher OH^- concentration, and at lower ones they approach a limiting value. This suggests the idea, that reaction (3) plays the part of a pre-equilibrium and the exchange of NCS^- for OH^- takes place with both species I and II, but the pathway of the reaction is different. Species I undergoes an aquation

0.875	3.82	5.62	8.51	—	—	—	—	—	—

followed by a rapid deprotonation

$$[Co(DH)_2(OH)(H_2O)] = [Co(DH)_2(OH)_2]^- + H^+ \quad (5)$$

due to the alcalinity of solution. In the case of species II a second order olation reaction may be presumed, according to the equation

$$[Co(DH)(D)(OH)(NCS)]^{2-} + OH^- = [Co(DH)(D)(OH)_2]^{2-} + NCS^- \quad (6)$$

On the basis of this scheme the following relation can be derived

$$k_{\text{exp}} = -\frac{K}{K_w}(k_{\text{exp}} - k_2\,[OH^-])\,[OH^-] + k_1 \quad (7)$$

where K stands for the equilibrium constant of reaction (3), k_1 and k_2 for the rate constants of reactions (4) and (6), respectively, and K_w for the ionic product of water.

Since at high OH^- concentration equilibrium (3) must be shifted towards the formation of species II and the activation energy required for reaction (4) is presumably rather high, one may assume reaction (6) to be practically the only reaction taking place at low temperatures and high OH^- concentrations.

At temperatures between 18 and 27° a large excess of OH^- has been used and second order rate constants of reaction (6) may be derived simply by deviding k_{exp} by $[OH^-]$. Values are presented in table 2.

Table 2

Second order rate constants for reaction (6) ($k_2 \times 10^5$, $M^{-1}\ s^{-1}$)

$[OH^-]$ mole/l	18°	21°	24°	25°	27°
0.505	—	—	—	11.2	—
0.523	4.51	6.56	9.67	—	14.3
0.611	—	—	9.79	—	14.4
0.675	—	—	—	11.0	—
0.699	4.15	6.22	9.60	—	14.2
0.787	—	—	9.50	—	—
0.845	—	—	—	10.9	—
0.875	4.37	6.42	9.72	—	—

The rather good constancy of the k_2 values obtained for different OH^- concentrations are consistent with the scheme presumed. The graphical plot of log k_2/T versus $1/T$ (fig. 3) enabled us to derive the following activation enthalpy and entropy values:

$$\Delta H_2^{\neq} = 22.5 \pm 0.4 \text{ kcal/mole}; \quad \Delta S_2^{\neq} = -1.2 \pm 1.1 \text{ Cl.}$$

By using these parameters, the following k_2 values can be calculated:

t°	18	21	24	25	27	30	35	38	40
$k_2 \times 10^5$, $M^{-1}s^{-1}$	4.28	6.45	9.61	10.9	14.2	20.7	38.8	55.8	70.9

which enabled us to derive K and k_1 values according to eq. (7). The graphical plot of $k_{\exp}$ versus $(k_{\exp} - k_2[OH^-])[OH^-]$ gave the straight lines represented in fig. 4.

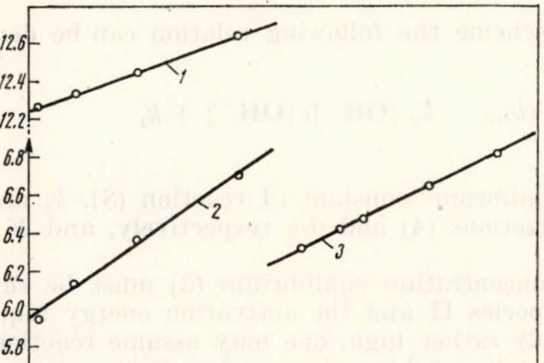

Fig. 3. — Determination of thermodynamic and kinetic parameters of the reactions (3)—1, (4)—2and (6)—3.

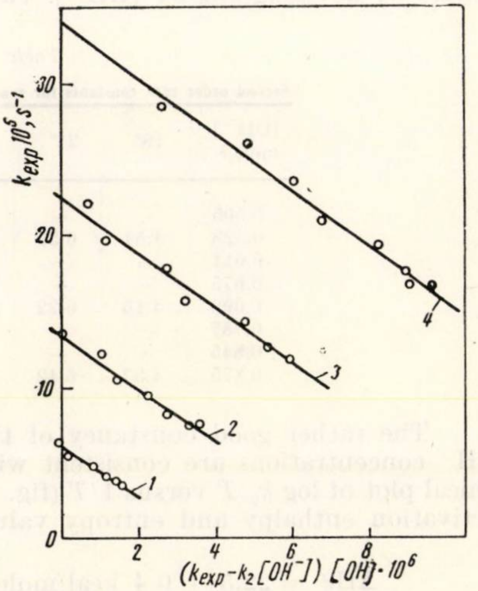

Fig. 4. — Graphical determination of k_1 and K on the basis of equation (7), 1—30°, 2—35°, 3—38°, 4—40°.

From the zero concentration ordinate and from the slope of the straight lines obtained, k_1 and K values given in table 3 have been derived. For K_w literature data [20] have been used.

---

[20] K. P. MISCHENKO and A. A. RAVDEL, "Kratkii spravochnik fizikokhimicheskikh velicin", Izd. Khimia, Moscow, 1965, p. 106.

Activation enthalpy and entropy values for reaction (4) have been derived by using the linear relationship between $\log k_1/T$ and $1/T$ and reaction enthalpy and entropy for reaction (3) in a similar way, by performing the graphical plot of $\log K$ versus $1/T$ (see fig. 3).

Table 3

Rate constants of reaction (4) and equilibrium constants of reaction (3)

$t°$	$k_1 \times 10^5, s^{-1}$	$K \times 10^{13}$
30	5.86	2.30
35	13.3	3.54
38	22.5	4.67
40	34.0	5.32

Results obtained are the followin :

$$\Delta H_1^{\neq} = 32.2 \pm 0.5 \text{ kcal/mole}; \quad \Delta S_1^{\neq} = 28.4 \pm 1.3 \text{ Cl}$$

$$\Delta H = 16.1 \pm 0.3 \text{ kcal/mole}; \Delta S = -4.8 \pm 1.0 \text{ Cl}$$

DISCUSSION

Data derived from kinetic measurements plead for the correctness of our scheme presumed, i.e. there is a protolytic pre-equilibrium, which involves the break up of one of the O–H..O hydrogen bridges. Due to this equilibrium the complex studied showed the behaviour of a weak acid, viz. it is a weaker acid than the analogous dinitro- and nitro-hydroxo complexes. [17] It is apparent the coordinated nitro and thiocyanato group to have a considerable *cis*-effect. Meanwhile, the smaller the acidity constant, the larger the reaction enthalpy of the acid dissociation.

The species $[Co(DH)_2(OH)(NCS)]^-$ undergoes an aquation according to equation (4).

The activation enthalpy has nearly the same value as for the aquation of the species $[Co(DH_2)(DH)(NCS)_2]$.

This is not surprising, since the electrostatic effect compensates the difference between the *trans* effect of the OH and NCS groups. The negative charge of species I makes easier the break up of the Co–NCS bond as compared to neutral molecules, but in the case of the species $[Co(DH_2)(DH)(NCS)_2]$ the presence of another NCS group in *trans* position has nearly the same effect.

The species $[Co(DH)(D)(OH)(NCS)]^{2-}$ undergoes an olation reaction described by equation (6).

The activation enthalpy required is with 10 kcal less, than for species I. The higher negative charge alone cannot explain such a large difference and one may presume also a difference in mechanism. The very low activation enthalpy value and the partial reaction order with regard to OH^- ions suggests the idea the mechanism of reaction (6) to be S_N2, and that of reaction (4) S_N1.

In the case of the analogous dinitro- and nitro-hydroxocomplexes instead of the olation a very aquation reaction has been observed. One can presume the different behaviour to be the result of steric hindrance, which makes impossible the S_N2 olation pathway in the case of coordinated nitro-groups.

EXPERIMENTAL

Synthesis of $[Co(DH)_2(H_2O)(NCS)] \cdot 2\,H_2O$. 0.1 moles of cobalt acetate (25 g) and 0.3 moles of KCNS (30 g) are solved in 500 ml water, the hot solution of 0.2 moles of dimethylglyoxime (23 g) in about 0.8 l ethanol is added and the mixture is oxidized by bubbling air for 5–6 hours. The precipitate of $Co^{II}[Co(DH)_2(NCS)_2]_2$, formed as by-product, is filtered and the brown solution is treated, under continuous stirring with 50–60 ml 10 p.c. ammonia, added drop by drop.

Light brown crystalline product is formed. It is filtered, washed several times with water and dried on air. Yield : 70 %.

Anal. Found : Co = 15.15 ; S = 8.10 ; H_2O (cryst. water) = 8.60. *Calc.* for $Co(C_4H_7\,N_2O_2)_2$ H_2O (NCS)$\cdot 2\,H_2O$; Co = 15.03 ; S = 7.99 ; H_2O (cryst. water) = 8.98.

IR spectrum has been recorded in KBr pellets, by means of a UR 10 Carl Zeiss Jena spectrophotometer, from 400–4000 cm^{-1}.

Kinetic measurements. Samples weighed have been solved in distilled water preheated to the working temperature. Standard NaOH solution has been added in order to ensure the needed OH^- concentration (taking into account the base necessary for the aquo-hydroxo transformation) and standard $NaNO_3$ solution, necessary for the ionic strength of 1 M. Samples of the complex of about 5×10^{-3} M were kept in ultrathermostat at working temperature, with an accuracy of $\pm$ 0.1°. 9 different working temperatures were used between 18 and 40°. Samples of 5 ml were taken out at different intervals, acidified with HNO_3, and the concentration of the NCS^- ions liberated was determined by means of potentiometric titrations. In the titrations 10^{-2} M $AgNO_3$ solution has been used. Indicatory electrode : silver wire.

Revue Roumaine de Chimie, **18**, *3*, 425–430 (1973)

NEW THORIUM COMPLEXES WITH PYRIMIDINE DERIVATIVES

FLORICA POPEA and CRISTINETA MĂRCULESCU

Centre of Physical Chemistry,
Str. Dumbrava Roşie, 23 Bucharest

Received August 17, 1972

In the present note, the new thorium compounds of the $ML_4 \cdot nH_2O$ type (M= Th ; L =barbituric or thiobarbituric acid), their chemical analyses, thermal behaviour, X-ray diffraction data, reflectance and i.r. spectra, are reported.

Following the researches concerning the reactivity of pyrimidine derivatives with 5f elements, in a previous work, the thorium nitrate-water-violuric (isonitrosobarbituric) acid system was studied spectrophotometrically [1].

Recently, [2] based on the reactivity of the 5-position and on the tautomery of the hydrogen atoms in the 1,3—positions of the pyrimidine ring, there has been interest to obtain solid compounds in the reaction of the uranyl ion with pyrimidine derivatives.

The present article describes the results on the investigations aimed to obtain new solid thorium compounds in the reaction with barbituric, thiobarbituric, monosubstituted at the C_5 barbituric acids (5-aminobarbituric and 5-ethylbarbituric acids), and with nonsubstituted at the C_5 (1-phenyl and 1,3-biphenyl)-barbituric acids.

The only unitary products obtained, are of the general formula $ML_4 \cdot nH_2O$ (M = Th ; L = AB or ATB). They resulted from the direct reaction, in aqueous solution, in stoichiometric amounts of thorium nitrate pentahydrate and barbituric (AB) or thiobarbituric acid (ATB) maintaining strictly the conditions indicated.

EXPERIMENTAL

Reagents. Thiobarbituric acid, 5-ethylbarbituric acid, 1-phenyl and 1,3-biphenylbarbituric acid were synthesized and purified, using the classical methods.

The following reagents (reagent grade), were used without additional purification : $Th(NO_3)_4 \cdot 5H_2O$ E. Merck, $AB \cdot 2H_2O$ — Carlo Erba and 5-aminobarbituric acid — Fluka.

Syntheses of Th[AB]$_4$·2H$_2$O *and* Th[ATB]$_4$·9H$_2$O

The two compounds were prepared by the same procedure. A 20 ml. aqueous suspension of 0.002 M AB·2H$_2$O or ATB was heated on boiling. The clear solution obtained (yellow with ATB) was treated with 0.0005 M thorium nitrate pentahydrate, stirring vigorously and keeping the same temperature for 5′ more. The solution became turbid and on cooling at room temperature, the compound I separated after 2 hours and II after only 60′. They were filterd, washed with 10 ml water, ethanol, ethilic ether and air dried.

The composition of the 2 compounds was determined based on the chemical analysis and namely : the metal by ignition as oxide (ThO$_2$), nitrogen, carbon and hydrogen by microcombustion.

Anal.		Th%	C%	H%	N%	H$_2$O%
I —	*calcd.*	29.88	24.74	2.08	14,43	4.28
	found	29.83	24,71	2.38	14.39	—
II —	*calcd.*	24.00	19.87	3.13	11.59	16,77
	found.	24.07	20.04	3.31	11.95	16.47

The white shining compound I microcrystals are stable at room temperature for a long time, but the II white-yellowish ones decompose on heating ; they are practically insoluble in the common solvents (ethanol, methanol, acetone, ethylic ether, T.H.F., D.M.F. and DMSO) and insoluble even in warm water.

The thermal behaviour, X-ray diffraction data, u.v. and visible reflectance spectra as well as the vibration i.r. spectra of the compounds were also studied.

RESULTS AND DISCUSSIONS

THERMAL BEHAVIOUR

The thermal curves were recorded on a MOM E. Paulik, J. Paulik—L. Erdey Derivatograph in the 30°—300° thermal range, in air atmosphere, with a 5°/min rate, using Al$_2$O$_3$ as standard and an amount of 0.4—0.5 g. for each sample.

For the compound II, the TG and DTG curves (fig. 1) reveal a continuous loss of weight between 50° and 200° ; the 16.47% value in agreement with the 16.77% one, calculated based on the analytical data corresponds to 9 water molecules for a molecule of anhydrous compound. Starting with this temperature, till 280° a horizontal level follows, characteristic for the anhydrous substance, and then a more abrupt loss of weight due to its decomposition. The DTA curve indicates an endothermic effect, with a maximum at 170°, and at 285° begins the decomposition with exothermic effect.

The thermal analysis was not conclusive for the II compound. The TG curve evidences a continuous loss of weight between 205° and 300°, but does not allow to recognize the end of the water removal, due probably to the simultaneous decomposition of the compound.

The thermal behaviour of the compounds was followed also with a Boetius heating plate.

On heating, at about 100°, Th[AB]$_4$·2H$_2$O begins to expel water and appear modifications, emphasized with the rise of the temperature. At 250° changes of the colour are observed, as a consequence of the

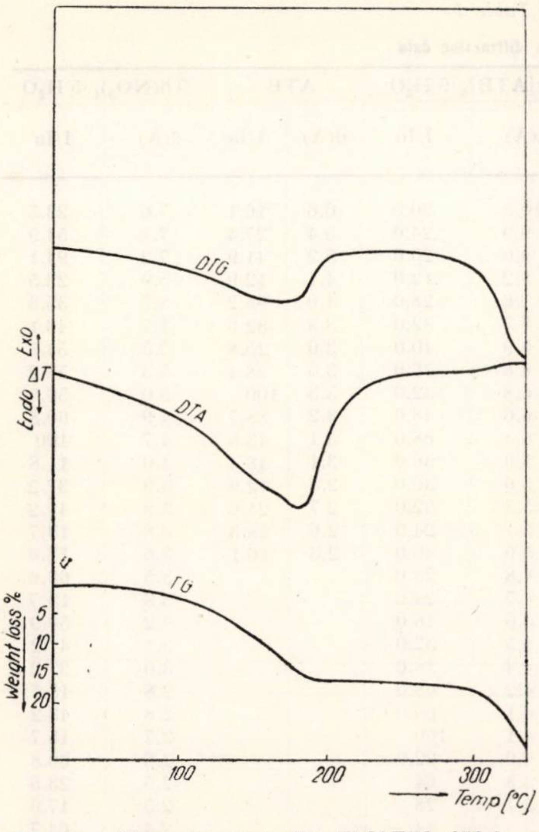

Fig. 1. — Thermal curves for Th[ATB]$_4$·9H$_2$O.

decomposition undergone by the whole mass, till 320°, but no net melting point can be observed.

As soon as 75°, Th[ATB]$_4$·9H$_2$O exhibits variations of the volume and a movement in the whole mass, till 235°, the beginning of the decomposition. The effect reaches a maximum at 285° and a sulfur odour is perceived, although till 320°, a sharp melting point can not be observed. As to be seen, the observations on heating the compounds by means of a Boetius heating table agree with those obtained by the thermal curves.

X-RAY DIFFRACTION STUDIES

The X-ray diffraction spectra were recorded on a URS. 50. IM equipment and the intensity data were collected on a diffractometer with Geiger-Müller counter. The Cu$_{K\alpha1}$ radiation ($\lambda = 1.5418$ Å and nickel filter) was used; no correction was made for the absorption.

As to be seen (table 1) the compounds are unitary and pure, free of thorium nitrate and of ligand. On the other hand, the diffractograms exhibit well defined lines in the region of small Bragg θ° angles. This observation substantiates a low symmetry and a large elementary cell. The different number of crystallization water molecules in these compounds, indicates their lack of symmetry.

ELECTRONIC SPECTRA

The reflectance spectra were recorded with a VSU-1 Jena spectrophotometer, at room temperature from 260 nm (38,461 cm^{-1} to 1200 nm (8.333 cm^{-1}) using MgO as a standard.

Thorium [3] does not exhibit a proper absorption in the visible range and the absorption curves of I and II have only the general shape of those of the ligands, with some shifts and changes in the intensity.

As may be seen, in figs. 2 and 3, the absorption maxima present in the ligands at about 300 nm (30.303 cm^{-1}) reappear in I at 285 nm (3.588 cm^{-1}) and at 330 nm (3.333 cm^{-1}) and in II at 315 nm (3.174 cm^{-1}) and the absorption maxima in the 420 nm (2.325 cm^{-1}) — 450 nm (2.222 cm^{-1})

---

[3] CL. DUVAL, "Traité de micro-analyse minérale", vol. 2, Presses scientifiques internationales, Paris, 1955, p. 70, p. 95.

range reappear in I at 395—405 nm (2.531—2.469 cm^{-1}) and in II at 455 nm (2.197 cm^{-1}).

Generally, as for the corresponding uranyl compounds, the characteristic absorption maxima of the ligands appear much weakened or as simple inflexions in the two compounds.

INFRARED SPECTRA

The vibration spectra, in the infrared were recorded on a UR-20 C. Zeiss spectrophotometer within the 400—1800 cm^{-1} range, using the technique of the pelleted powders (with KBr).

As may be seen in table 2, the absorption bands assigned to the pyrimidine ring, are present in the AB and the ATB ligands and also appear in the two new corresponding compounds, with more or less important changes in their position and their intensity. The absorption maxima at 1402, 1460 and 1570 cm^{-1}, due to the in-plane vibrations of the pyrimidine ring are to be found at 1400, 1490 and 1560 cm^{-1} in $AB.2H_2O$ and in the compound I at 1405, 1480 and 1620—40 cm^{-1}; in ATB at 1400, 1440 and 1600—40 cm^{-1}, and in the compound II at 1388, 1450, and 1610—40 cm^{-1}. The bands ascribed to the out-of-plane vibrations at 680—724 cm^{-1} appear at 680 cm^{-1} in $AB.2H_2O$, at 730 cm^{-1} in ATB and reappear at 705 cm^{-1} in I. In the compound II, this band is to be found at 707 cm^{-1} but much weaker probably due to the environment of the 9 water molecules of the compound.

In addition, the absorption band at 1540 cm^{-1}, characteristic for the $-S-\acute{C}=$ vibration is to be seen in ATB and appears also in the compound II.

CONCLUSIONS

The two new compounds obtained and characterized by chemical analysis and physical data, may suggest the enolic form as being more probable for the ligands in the reaction with thorium ion. The assumption is also supported by the spectral studies.

Revue Roumaine de Chimie, 18, 3, 431–439 (1973)

ON SOME DERIVATIVES OF THE HYDRAZINOCARBOXYLIC ACID. II

SYNTHESES AND SPECTRAL DATA

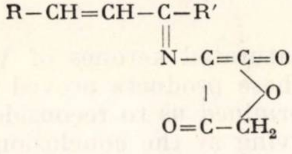
SCHELY AVRAMOVICI, I. DRUȚĂ and I. ZUGRĂVESCU

Department of Organic Chemistry "Al. I. Cuza" University, Iassy, Romania

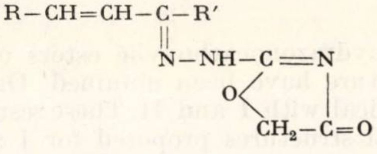
Received August 10, 1972

The synthesis of some hydrazonocarboxylic esters, previously obtained by the condensation of the corresponding semicarbazones with monochloroacetic acid, was carried out now directly. It was also proved that some products considered to have a 3-ketimino-2,4-oxazolidindione structure or a 4-oxazolone-2-hydrazonic one, are also hydrazonocarboxylic esters. The structure of the products is investigated by chemical analysis and IR and NMR spectral data.

In a previous paper, [1] the results obtained in the study of the condensation reaction between monochloroacetic acid and some semicarbazones of unsaturated aromatic ketones were published. In these cases the formation of different kinds of products with close analytical values was possible, whose structures were difficult to be elucidated. On the basis of elementary analysis and IR spectra, we have attributed a 3-ketimino 2,4-oxazolidindione structure (I) to the products isolated by the condensation of the studied semicarbazones with monochloroacetic acid in isopentyl alcohol in the presence of the triethylamine, and a 4-oxazolone 2-hydrazone structure (II) to the products isolated when the condensation takes place in ethyl alcohol in the presence of natrium acetate:



I



II

Then, the study was extended to the semicarbazones of saturated aromatic aldehydes and ketones. [2] We have proved that the reaction, in various alcohols used as solvents, leads to the separation of hydrazonocarboxylic esthers (III) as main products :

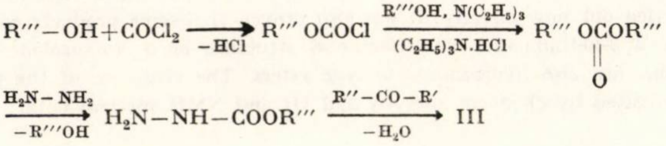
$$\begin{matrix}R'' \\ R\end{matrix}\!\!>\!C=N-NH-COOR'''$$

III

The structure which has been attributed to the final products was deduced from the interpretation of the analytical and spectral data, because the intermediaries which appeared in the different stages of the reaction could not be isolated.

In the present paper the possibility of III-type products obtained in another way of synthesis was studied. This made it possible for us to confirm the structures previously supposed. For this purpose, the isopentyl and *n*-hexyl esters of the hydrazinocarboxylic acid (IV), the new products were prepared and afterwards condensated with the same aromatic aldehydes and ketones :

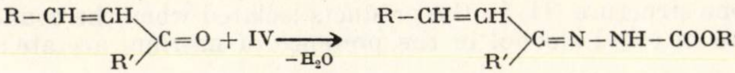


$$R'''-OH+COCl_2 \xrightarrow[-HCl]{} R'''\,OCOCl \xrightarrow[(C_2H_5)_3N.HCl]{R'''OH,\ N(C_2H_5)_3} R'''\,O\underset{\underset{O}{\|}}{C}OR'''$$

$$\xrightarrow[-R'''OH]{H_2N-NH_2} H_2N-NH-COOR''' \xrightarrow[-H_2O]{R''-CO-R'} III$$

IV

After obtaining these results the problem was put whether the I and II structures corresponded to reality. In order to see if these products are not also hydrazonocarboxylic esters we have achieved the condensation of the ethylic and isopentylic esters of the IV-type hydrazinocarboxylic acid with the unsaturated aromatic ketones initially used for the synthesis of the semicarbazones, which led to the products of previously attributed I and II structures. According to the reaction :



$$\begin{matrix}R-CH=CH \\ R'\end{matrix}\!\!>\!C=O + IV \xrightarrow[-H_2O]{} \begin{matrix}R-CH=CH \\ R'\end{matrix}\!\!>\!C=N-NH-COOR'''$$

V

the hydrazonocarboxylic esters of some unsaturated ketones of V-type structure have been obtained. On analysis these products proved to be identical with I and II. These results has determined us to reconsider the initial structures proposed for I and II, arriving at the conclusion that these products are not 3-ketimino 2,4-oxazolidindiones (I) or 4-oxazolon 2-hydrazones (II) but, hydrazonocarboxylic esters of V-type.

For the interpretation of the IR and NMR spectra the products III-H, V-G and V-H, mentioned in table 1, which served as comparison term, were also synthesized.

In all, nine hydrazones of the isopentyl ester, two hydrazones of the *n*-hexyl ester and five hydrazones of the ethyl ester of the hydrazinocarboxylic acid, corresponding to the III and V structures, have been separated and identified.

The IR spectra were registered with a SP 200 UNICAM spectrophotometer, using the KBr pellet technique; the most important and characteristic bands are given in table 2.

The NMR spectra were registered with a 60 MC JEOL apparatus at 20°, using as solvent $DCCl_3$ or CCl_4. The data are shown in table 3.

The IR and NMR spectra of the seven products described in the previous paper[2] are identical and they are not reproduced in the present work. The tables 2 and 3 contain only the characteristic spectral data of some of the newly synthesized products. From the beginning we must mention that these data are similar to those presented in the previous note. What is different is the presence of the olefinic double band which can be very well identified in the NMR spectra.

The two olefinic protons in the case of the V—A and V—E compounds provided two doublets in the NMR spectra, situated in the interval $\delta = 6-7.18$ ppm with a coupling constant particularly great, namely $j = 16$ c/s. In the cases of V—C and V—F compounds these protons are placed in the interval $\delta = 6.5-7.33$ ppm, the coupling constant being comprised between 8.3—8.6 c/s.

As in the case of the products discussed in the previous work, the IR spectra of those compounds are characterized by the presence of the corresponding $\rangle C{=}O$ ester group, located between 1690—1740 cm^{-1} and that corresponding to the antisymmetrical vibration $\rangle C{-}O{-}C\langle$ between 1230—1290 cm^{-1}. The ester group can be noticed also in the NMR spectra, in which the protons from the α-ester position appear between $\delta = 4.16-4.27$ ppm; the protons attached to the β-esteric carbon appear at about $\delta = 1.33$ ppm in the $-CH_3$ case group and at about $\delta = 1.66$ ppm in the $-CH_2-$ case group. Otherwise, the presence of this grouping in the NMR spectra represents the most important proof of a III or V-type linear structure formed in all the cases. The forming of I or II-type structures would have led to the absence of the signals and coupling corresponding to the esters alkyl groups and to the appearance of a singlet representing the methylenic group from the cycle in the NMR spectra. In the case of the I-type compounds, this singlet would have been situated round the value $\delta = 5.1$ ppm and in the case of type II compounds at $\delta = 5.2$ ppm, which was not noticed.

Concerning the —NH— group, the characteristic band in IR spectra is present in the 3200—3300 cm^{-1} region, while in the NMR spectra the proton of this group furnished a singlet situated at δ varying between 7.55—8.48 ppm, according to the structure. The presence of this proton in all spectra also represented a proof that instead of the supposed cyclic structures I we must take into account the V formulated structures.

EXPERIMENTAL

1. *Isopentylchloroformate* (B.p. $=154.3°$, $D_{15}=1.032$) and *Isopentylcarbonate* ($B.p._{17mmHg} = 105-110°$, $D_{15} = 0.912$) was obtained after reference material.[4]

2. *n-Hexylchloroformate* ($B.p._{18mmHg} = 78°$, $D_{22} = 1.066$) and *n-Hexylcarbonate* ($B.p._{10mmHg} = 132-138°$, $D_{24} = 0.857$) were obtained in a similar manner.

3. *The hydrazinocarboxylic esters.*

The general method. A mixture of 5 ml isopentyl or *n*-hexylcarbonate and 2.5 ml hydrazinehydrate in 10 ml anhydrous ethanol is stirred for 6–8 hours and then is kept at room temperature for a long time. Gradually, as the solvent evaporates, the hydrazinohydrate smell disappears and a characteristic esteric smell appears. An oily, colourless liquid which is distilled at low pressure remains.

– The isopentyl ester of the hydrazinocarboxylic acid.
$B.p._{12mmHg} = 115-122°$, $D_{20} = 0.977$

– The *n*-hexyl ester of the hydrazinocarboxylic acid.

B.p.$_{14mmHg}$ = 140–144°, D_{20} = 0.983.

– The ethyl ester of hydrazinocarboxylic acid was obtained after reference material.[3]

4. *The hydrazonocarboxylic esters*

The general method. To a mixture of 1.5 mole ester of the hydrazinocarboxylic acid and 1 mole carbonilic compound solved in a small quantity of alcohol, 2–3 drops of acetic acid are added. In some cases the condensation products separate immediately, in others it is necessary to stir or to heat for a short time. As sometimes, a partial transesterification takes place at the same time with condensation, it is indicated to use, both at synthesis and at recrystallization, the alcohol which had esterificated the hydrazinocarboxylic acid. The recrystallization is done by alcohol, alcohol-water or ethylacetate.

Thus, all the products presented in table 1 were separated with 50–80% efficiency. Their analytical data are synthesized in table 4. In some cases their melting points differ. They are in general a little higher than in the previous papers,[1,2] because of their higher purity.

CONFIGURATIONS OF SUBSTITUTED DIBENZOBICYCLO [3.2.1]OCTADIENES*[1]

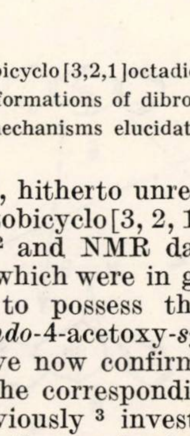
MARGARETA AVRAM, I. G. DINULESCU and C. D. NENITZESCU
Organic Chemical Institute, Bucharest, Romania

RICHARD A. Y. JONES, A. R. KATRITZKY and R. J. WYATT
School of Chemical Sciences, University of East Anglia, Norwich, NOR 88 C

Received October 6, 1972

The configurations of dibenzobicyclo[3,2,1]octadienes prepared by solvolysis and the course of further transformations of dibromodibenzo-bicyclo[4,2,0] octadiene are confirmed and the mechanisms elucidated.

There is a long-standing, hitherto unresolved, discrepancy regarding the configuration of dibenzobicyclo[3, 2, 1]octadienes (**1**). In 1964 we published chemical evidence [2] and NMR data [3] for the configuration of a series of these compounds, which were in good agreement *except* for one compound which appeared to possess the *exo*-4-acetoxy-*syn*-8-bromo structure on NMR but the *endo*-4-acetoxy-*syn*-8-bromo structure on chemical evidence (*cf* **1**). We have now confirmed the *exo* configuration for this compound, shown that the corresponding hydroxy compound [2] (the NMR of which was not previously [3] investigated) also possess the *exo* configuration, and elucidated the mechanisms of the reaction sequences which appeared earlier to suggest the opposite configurations at the 4-position.



1

Solvolyses of dibromodibenzobicyclo[4, 2, 0]octadiene (**2**) give [2] C_4-substituted *syn*-8-bromodibenzobicyclo [3,2,1]octadienes : acetolysis yields the 4-acetoxy derivative (**3**), hydrolysis yields the 4-hydroxy deri-

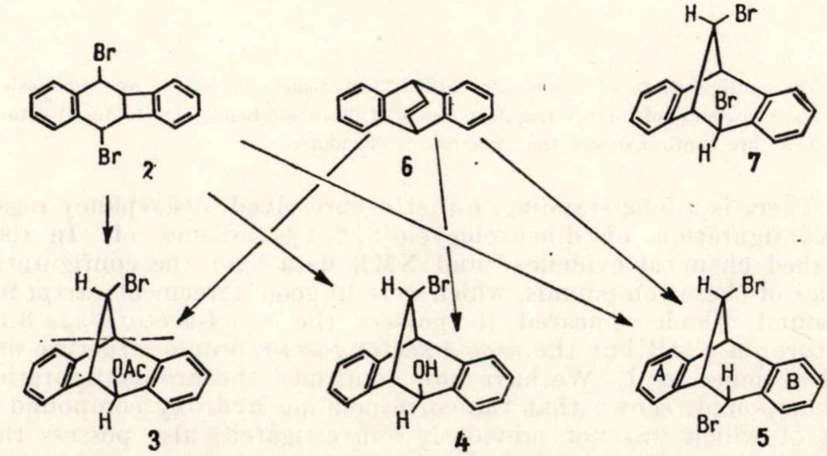
vative (**4**), and in the presence of AgBr **2** is isomerized to the 4-bromo-compound (**5**). The same products were obtained [2] from dibenzobicyclo [2,2,2] octadiene (**6**) by reaction with bromine in acetic acid, by reaction with bromine in a mixture of tetrahydrofuran and water, and by simple addition of bromine, respectively. Chemical evidence was correctly adduced for the *endo*-orientation of the bromine at C-4 in **5**; the *endo*-configuration for the acetoxy and hydroxy groups in **3** and **4** appeared at that time to follow from simple transformations from **5**. However, Cristol and coworkers [4] independently reported the formation of **3** and **4** from **6**, assigning them the *exo*-configurations given in the structures (*cf*-also Ref. [5]).

Scheme 1



The isomerization of **2** with an ionizing catalyst also yields the *endo*-dibromide **5** which is the thermodynamically stable isomer; Cristol and coworkers [6] concluded that in general *endo*-4-substituted compounds are more stable than their *exo*-analogues (*cf* **1**). The course of addition of bromine to **6** is probably subject to steric effects. In the addition of the less bulky chlorine at C-8, Cristol and coworkers [7] found that a mixture of 12% *syn*-8-*endo*-4-dichloro-derivative and 88% *exo*-derivative was formed.

PHYSICAL EVIDENCE AND ASSIGNMENT OF CONFIGURATIONS

(a) *Dipole moments*. We have determined the dipole moments of compounds **3**, **4** and **5** (Table 2) from the data recorded in Table 1. By the method of Table 3 we are able to show that the bromo-compound does indeed possess the *endo*-configuration (**5**). Unfortunately, several uncertainties, particularly the unknown rotational isomerism around the C—O bond, precludes any clear conclusion from dipole moments regarding the configuration of the hydroxy and the acetoxy compounds.

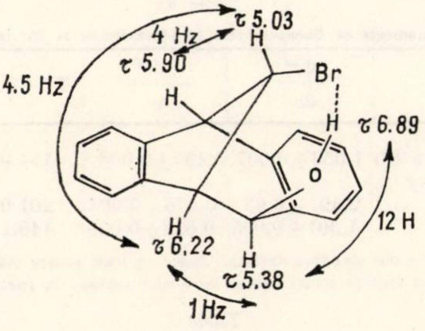
Table 4

Infrared unassociated ν OH band frequencies (cm⁻¹) for dibenzobicyclo [3,2,1] octadienes [a]

Substituents		Frequency for 4-OH group	
8 Position	4 Position	*exo*	*endo*
syn-Bromo	OH, H	3585	—
syn-Bromo	OH, Me	3570	—
H	OH, H	3620	3588
H	OH, Me	3625	3588

[a] Measured in CCl_4.

(b) *Infrared spectra.* The position of the unassociated νOH stretching band (Table 4) for 4-*endo*- and 4-*exo*-alcohols show that the *endo*-compounds have the lower frequency, but that the frequency of the *exo*-compounds is lowered by an 8-*syn* bromine substituent, which is in a favourable position for intramolecular hydrogen bonding with the hydroxy group (*cf* **8**). The infrared evidence is particularly helpful for relating the methyl series compounds with the desmethyl derivative (see later).



· 8

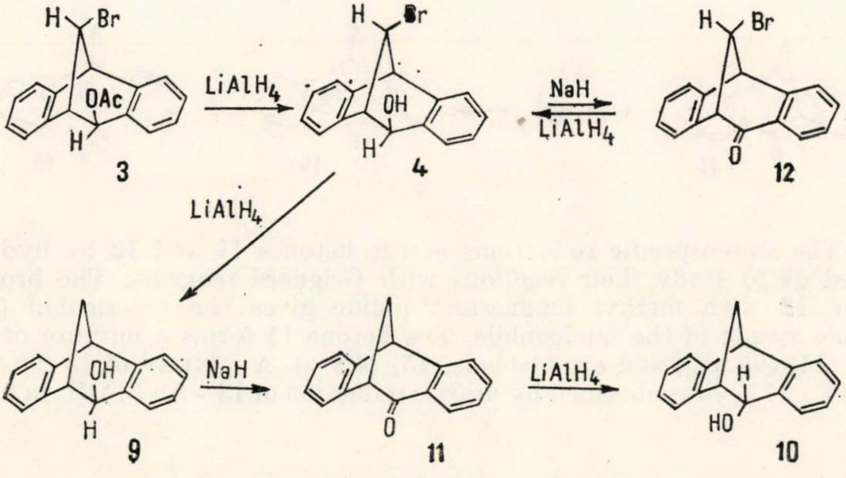
(c) *NMR spectra.* The spectra of the bromo-hydroxy derivative **8** shows clearly that it is the *exo*-hydroxy compound : in particular the small J_{45} is characteristic ; [5] other J and τ values are in good agreement with previous work on these compounds. [3] The large coupling between the *endo*-H and the hydroxy-H is further evidence for intramolecular hydrogen bond formation which holds these two hydrogens at a dihedral angle near 180°.

CHEMICAL EVIDENCE AND ELUCIDATION OF REACTION MECHANISM

The product of the reduction of the acetoxy derivative (**3**) with $LiAlH_4$ is affected by the purity of the reagent. Different specimens of $LiAlH_4$ gave either the *exo*- (**9**) or the *endo*-4-hydroxy compound (**10**) or a mixture of both. The structure of the alcohols **9** and **10** and of the corresponding acetoxy derivatives are supported by their spectra. Both alcohols (**9** and **10**) give on oxidation the same ketone (**11**).[4]

We first thought that the *exo*-alcohol (**9**) was initially formed in the reduction, and that it was converted into **10** in the presence of strong alkali in some reagent specimens. However, the *exo*-alcohol (**9**) (obtained by solvolysis of dibenzobicyclo [2,2,2] octadienol tosylate)[8] is recovered unchanged after heating with bases, e.g. KOH/EtOH. The *exo*-alcohol (**9**) on heating with sodium hydride in THF is converted in high yield to the ketone **11**;[9,10] similarly the alcohol **4** is converted to the ketone **12**. Reduction of the ketone **11** with $LiAlH_4$ gives as chief product the *endo*-alcohol (**10**) (92.5%) with a little isomer **9** (7.5%) as shown by Cristol and co-workers[4] and confirmed by us. However, reduction of the bromoketone **12** with $LiAlH_4$ gives the *exo*-alcohol **4**. The difference in the behaviour of the ketones (**11** and **12**) on reduction with $LiAlH_4$ must be ascribed to steric hindrance in **12** by the bromine atom at C-8 which directs attack of hydride ion from the less hindered *endo*-direction.

Scheme 2



These results support the mechanism of Scheme 2 for the formation of *exo*- (**9**) and *endo*-alcohols (**10**) from the bromoacetoxy derivative (**3**).

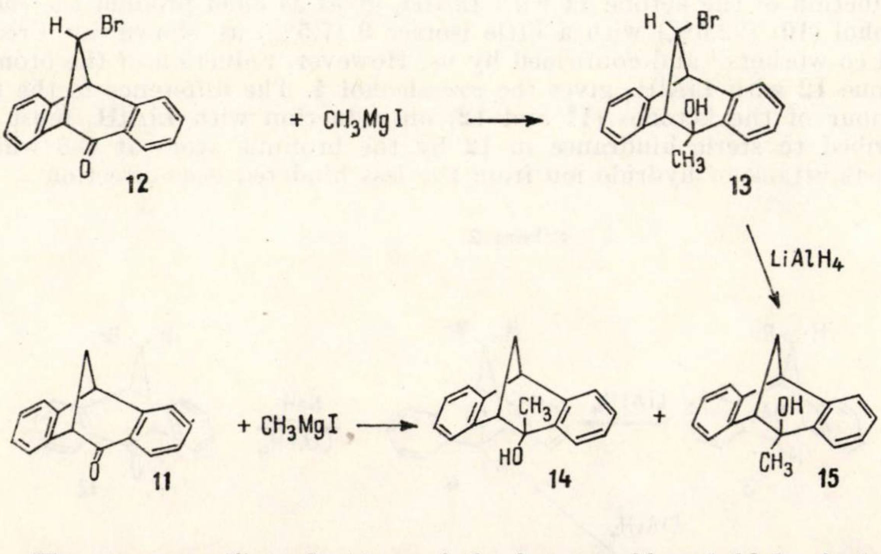
[9] E. Ciorănescu, A. Mihai and C. D. Nenitzescu, unpublished.

[10] For the oxidation of secondary alcohols to ketones in the presence of strong bases see W. von E. Doering and R. M. Haines, *J. Amer. Chem. Soc.*, **76**, 482 (1954); R. Cornubert and W. Kondrachoff, *Compte rend.*, **245**, 1362 (1957); B. Alexandre, R. Cornubert, Y. Fagnoni and W. Kondrachoff, *Bull. Soc. chim. France*, **1960**, 661; A. le Berre, *Bull. Soc. chim. France*, **1961**, 1193.

The initialy formed bromohydrin (**4**) is further reduced by $LiAlH_4$ to the *exo*-alcohol (**9**) which reacts with NaH (if this is present to give the ketone **11**, which in turn is reduced with $LiAlH_4$ stereospecifically to yield *endo*-alcohol (**10**). If any bromo-ketone (**12**) is formed from **4**, it is reduced by excess $LiAlH_4$ back to **4** again.

Scheme 3



The stereospecific reductions of the ketones **11** and **12** by hydride ion led us to study their reactions with Grignard reagents. The bromo-ketone **12** with methyl magnesium iodide gives the *exo*-alcohol (**13**), by *endo* attack of the nucleophile. The ketone **11** forms a mixture of the *endo*- (**14**) (95.2%) and *exo*-alcohols (**15**) (4.8%). A mixture of **15** (96.3%) and **14** (3.7%)was obtained by drastic reduction of **13** with $LiAlH_4$ inTHF.

EXPERIMENTAL

IR spectra were recorded with double beam Jena UR-20 and Perkin-Elmer Model 21 spectrophotometers. The NMR spectra were determined with Perkin-Elmer R 10 and Varian A 60-A instruments (TMS as internal standard). Gas-liquid chromatographic analyses were carried out on a Carlo Erba Model GD gas chromatograph, using 20% Carbowax 20 M, 1 m, 2 mm columns, H_2 (120 ml/min) as carrier gas, and a column temperature at 225°.

Reduction of exo-4-*acetoxy*-syn-8-*bromo*-2,3,6,7-*dibenzobicyclo*$_0$3,2,1]*octa*-2,6-*diene*(**3**) *with lithium aluminium hydride.* [Note : the $LiAlH_4$ reagent used varied in quality and came from different sources.] A. 3.5 g (10 mmol) **3** in anhydrous THF (60 ml) was heated under reflux for 48 hr with $LiAlH_4$ (2.0 g), then water was added, the ethereal solution was washed with water and evaporated. The oily residue was recrystallized from cycloheaxne yielding the *endo*-hydroxy compound **10** (1.7 g; 77%), m.p. 145°. (*Found*: C, 86.15; H, 6.43. *Calcd.* for $C_{16}H_{14}O$: C, 88.45, H, 6.35%). The alcohol **10** yielded an acetate m.p. 132° after recrystallization from MeOH. (*Found*: C, 81.95; H, 6.12. *Calcd.* for $C_{18}H_{16}O_2$: C, 81.80; H, 6.10%).

B. 0.5 g **3** in THF (10 ml) was heated under reflux for 48 hr with $LiAlH_4$ (0.5 g) and NaH (0.1 g). Treatment as in A above yielded the *exo*-hydroxy compound **9** with 2% **10**.

C. 1 g **3** in THF (20 ml) was heated under reflux for 48 hr in argon with $LiAlH_4$ (1 g) and LiH (0.3 g). Treatment as in A yield only the *exo*-alcohol **9**.

D. 3.5 g **3**, THF (60 ml) and $LiAlH_4$ (2 g) were heated under reflux for 48 hr. Treatment as in A yielded only the *exo*-alcohol **9**.

Reaction of the ketone **11** *with lithium aluminium hydride.* 1 g **11** in ether (25 ml) were heated under reflux 1 hr with $LiAlH_4$ (1 g). Treatment as before gave a mixture of **10** and **9** in the ratio 92.5 : 7.2, determined by gas-liquid chromatography.

Reaction of the ketone **12** *with lithium aluminium hydride.* 0.5 g bromo-ketone **12** in ether (20 ml) was left with $LiAlH_4$ (0.5 g) for 3 hr at room temperature. Treatment as before yielded bromo-alcohol **4** (0.4 g; 80%), with IR and NMR spectra identical to those of an authentic sample.

Reaction of the bromo-alcohol **4** *with sodium hydride.* 0.5 g **4** in THF (10 ml) was heated under reflux for 8 hr with NaH (0.3 g). Treatment as before gave bromo-ketone **12** (0.3 g), with IR spectrum identical to that of an authentic sample.

Attempts to isomerize exo-*alcohol* **9** *to* endo-*alcohol* **10**. A. The *exo*-alcohol **9** (0.5 g) in THF (10 ml) was heated under reflux with NaH (0.3 g) for 4 hr. $LiAlH_4$ (0.3 g) was added and the mixture heated under reflux for 4 hr. Treatment as before yielded the *endo*-alcohol **10** (identified by m.p. and IR spectrum).

B. 0.5 g **9** in THF (10 ml) when heated under reflux with NaH (0.3 g) and $LiAlH_4$ (0.3 g) for 2 hr yielded **9** and **10** in the ratio 66 : 33, determined by gas-liquid chromatography.

C. 1 g **9** in THF (20 ml) when heated under reflux with $LiAlH_4$ (0.5 g) for 48 hr gave only the starting material.

D. **9** was recovered unchanged after heating under reflux for 24 hr with 20% alcoholic KOH.

Attempts to isomerize exo-*alcohol* **4**. **4** gave rise only to starting material when heated under reflux for 24 hr with 20% alcoholic KOH.

Reaction of the ketone **11** *with methyl mangesium iodide.* 1.0 g **11** in ether (20 ml) was added dropwise to a solution of methyl magnesium iodide [prepared from Mg (0.4 g) and MeI (2.5 g) in ether (20 ml)] and the mixture kept at room temperature overnight. Work-up as before followed by chromatography on alumina with ether gave an oil (0.6 g) which contained **14** and **15** in the ratio 95.2 : 4.8, determined by gas-liquid chromatography (*Found*: C, 85.51; H, 7.05. *Calcd.* for $C_{17}H_{16}O$: C, 86.41; H, 6.82%).

Reaction of the bromo-ketone **12** *with methyl magnesium iodide.* 1.0 g **12** was treated as above to yield the *exo*-alcohol **13** (0.7 g), m.p. 105° after recrystallization from MeOH (*Found*: C, 64.95; H, 5.02; Br, 25.65. *Calcd.* for $C_{17}H_{15}BrO$: C, 64.78; H, 4.80; Br, 25.36%).

Removal of bromine from **13** *with lithium aluminium hydride.* Bromo-alcohol **13** (0.5 g) in THF (15 ml) was heated under reflux for 48 hr with $LiAlH_4$ (0.5 g). Treatment as before and chromatography on alumina with ether gave rise to **15** and **14** in the ratio 96.3 : 3.7 as determined by gas-liquid chromatography.

Acknowledgement. We thank Professor S. J. Cristol for helpful correspondence and access to unpublished data.

PEPTIDE SYNTHESES WITH N-(ACYL-*o*-NITROPHENYL)-SUBSTITUTED AMINO ACIDS

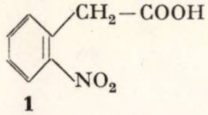
FLAVIAN CUIBAN

Department of Industrial Chemistry, Polytechnical Institute "Traian Vuia",
Timişoara, POB 103, Romania

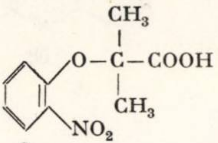
Received October 27, 1972

Several N-acylated amino acids with *o*-nitrophenyl-acetyl or 2-methyl-2-*o*-nitrophenoxy-propionyl groups were synthetized and their behaviour during peptide syntheses was investigated. Better results were obtained with 2-methyl-2-*o*-nitrophenoxy-propionyl protected amino acids, which can be prepared with good yields without racemization. After peptide bond synthesis, the acyl residue is readily removed as cyclic lactam, by catalytic reduction under mild conditions and the aminopeptide is easily separated. Optical activity was preserved if in peptide bond syntheses mixed anhydrides or carbodiimides were used but only racemic products were obtained with acid chlorides of protected amino acids.

The use of *o*-nitrophenoxy-acetic and chloroacetic as aminoprotecting groups during peptide synthesis [1,2] could not be extended, because heating is necessary for removal of the protecting groups; this heating can favour some unwished secondary reactions. The study of the reduction of α- and β-*o*-nitrophenyl substituted amides, showed [3] that mainly *o*-nitrophenylacetic (**1**) and 2-methyl-2-(*o*-nitrophenoxy)-acid amides (**2**) present a pronounced tendency to lactamize after hydrogenation. Lactams result even at room temperature and the primary amine involved in carboxyl function amidation is eliminated. This behaviour suggested the possibility of using acids (**1**) and (**2**) as aminoprotecting groups in peptide synthesis. [4] In this paper, experiments are described for this purpose.



1



2

The acylation of amino acids with acid chlorides (**1** and **2**), in aqueous media buffered at $pH = 8-10$, did not yield satisfactory results because the acid chloride hydrolyzes partially. Good results were obtained when

the corresponding *p*-nitrophenyl esters were used instead of acid chlorides (whose preparation was described in a previous study [3]). N-Acylated amino acids (**3**—**13**) from table 1 were obtained without difficulties (see experimental part) as esters or free acids, depending on the raw material. Only compound (**4**) was obtained in two ways: by glycine acylation and by ester (**3**) hydrolysis. It was established on this occasion that for lysine diacylated products (**6** and **7**) are easily obtained; also the procedure enables to acylate selectively the terminal amine, but separation of pure product is more difficult. Details will be discussed in another work.

In order to test the elimination possibilities of acyl protecting groups from amino acids, catalytical reduction in standard conditions was used, adapting it to the case of *o*-nitrophenyl-substituted amides. [3] Diacylated lysine derivatives (**6** and **7**) and protected phenylalanine (**10**) were used as model substances. Phenylalanine can be considered as a representative of the other protected amino acids, since it does not raise special problems at the elimination process of the protecting groups. Using a diamino acid such as lysine, the order in which the two acyl groups are eliminated could be observed. The protecting group elimination was checked by TLC, on samples taken at various intervals and by separating the reaction products.

Considering the results obtained in the catalytic reduction of α- and β-*o*-nitrophenyl acid amides from the previous work, [3] the simplified reactions, which could occur in the reduction of N^{α}, N^{ε}-di(*o*-nitrophenyl acetyl)-lysine are given in scheme 1.

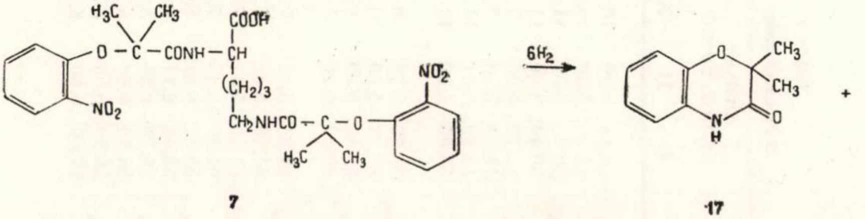
In our experimental conditions, neither hydroxylaminic derivatives (**6a**) resulted by partial reduction, nor 1,2-dihydroxyindole (**15**) could be evidenced in the reaction medium. At the end of the hydrogenation, most of the product appears as lysine (**14**) together with the corresponding equivalent of 2-hydroxyindole (**16**) alone with small quantities of monoacylated reduction products either in position ε (**6c**) or in α (**6d**). In TLC, they appear with very different Rf values, and are distinguished by ninhydrine colouring. For the N^{ε}-acylated derivative (**6c**) the colouring appears immediatly at cool, while the N^{α}-acylated (**6d**) derivative is coloured by ninhydrine only on warming or during a longer time at room temperature. Judging from the size of the spots and their colour intensity, the N^{ε}-acylated product (**6c**) appears in greater amount, and unlike (**6d**), traces of (**6c**) can be observed on the chromatogram even after preserving the reaction mixture for 24 hours at room temperature. By solvent elimination at 40—50°,the entire lysine appears free, indicating the full elimination of the protecting groups.

On hydrogenation of the diacylated derivative of lysine (**7**) with 2-methyl-2-(*o*-nitrophenoxy)-propionic acid, when hydrogen absorption stops, the entire amount of lysine occurs as free product. The reduced monoacylated derivatives, similar to products (**6c** and **6d**), were never obtained, but only the lactam and lysine (**14**) according to the reaction scheme 2.



Scheme 2. — The reduction of N,N-di-(2-methyl-2-*o*-nitrophenoxy-propionyl)-lysine.

The acyl residue elimination on reduction of the protected phenylalanine (**10**), occurred according to a similar scheme, yielding free phenylalanine and lactam (**17**). In all cases, the deprotected amino acid is obtained unracemized, in practically quantitative yield. Owing to the water insolubility of the secondary cyclic derivatives (**16**), and (**17**) respectively, the separation of free amino acids was achieved very easily. It was observed from these data, that unlike the model amides studied in the previous work, [3] in the case of acylated amino acids, perceptible differences in the elimination of *o*-nitrophenylacetyl protecting groups appeared in opposition to 2-methyl-(*o*-nitrophenoxy)-propionyl, the latter being eliminated more easily.

Although some other acyl groups for protecting the amine function in peptide synthesis are easily eliminated, they cannot be widely employed because in the activation stage of the carboxyl group, racemization occurs on account of azlactone formation. [5] The decomposition of the acylamino acids was noticed, when converted in acid chlorides [6] with $SOCl_2$ or PCl_5;

[5] A. Hillmann and G. Hillmann, *Z. Naturforsch.*, **6b**, 340 (1951).

[6] J. C. Sheehan and D. H. Jang, *J. Amer. Chem. Soc.*, **80**, 1154 (1958).

the peptide yields were poor, when the azide[7] method was used. The danger of racemization is greater in peptide syntheses with acylamino acids and it varies in function of the activation method (acid chloride, mixed anhydride, active ester, etc.) and experimental conditions (temperature, solvent nature, pH, etc.).

In order to investigate the racemization tendency and to test the behaviour of 2-methyl-2-(*o*-nitrophenoxy)-propionic amino acids for peptide bond formation, model substances with optically active amino acids were prepared, and different activation methods frequently applied for peptide preparation, were used. Finally, optical activity of different synthetized products was compared to authentic samples. Protected phenylalanine (**10**) was condensed with ethyl glycinate by means of acid chloride, mixed anhydride (with carbonic ester) or N,N′-dicyclohexylcarbodiimide (DCC). After total deprotection of the product (**20**) optical purity of phenylalanylglycine (**23**) was compared to optically pure product.[8]

(i) — As it appears in scheme 3, L-phenylalanine (**10**) was condensed with ethyl glycinate by means of acid chloride and yielded a completely racemized product. Racemization occurs even in the obtaining of acid chloride (**18**), since the solution resulted at chlorination lacks optical activity, while in alkaline hydrolysis the racemic protected amino acid results (**9**). By ethereal extraction of the acid chloride (**18**) an optically inactive product was separated, by which IR spectroscopy offers the characteristic absorption of azlactones in the 1835—1840 cm^{-1} range. This absorption band completely disappears on treating with triethylamine and *p*-nitrophenol in accordance with the results published by Young,[9] referring to base-catalyzed racemization of acylpeptides.

(ii)—In opposition to acid chloride activation *via* mixed anhydrides, dipeptide (**20**) was obtained, and after saponification of (**22**) and elimination of the protecting group, phenylalanyl glycine (**23**) presented optical activity as indicated in the literature. The condensation yield *via* mixed anhydrides is not quantitative (61.5%). By adequate processing of the reaction product, the unreacted carboxyl component (**10**) having initial optical activity, was isolated.

The obtention of an optically active product is in contradiction to the general remarks of several authors,[10–12] who noticed an advanced racemization, when mixed anhydrides for amino acid activation were used.

(iii)—Condensation of acyl-phenylalanine (**10**) with ethylglycinate in the presence of N,N′-dicyclohexylcarbodiimide affords very good yields (98%), and the resulted product (**20**—**23**) is optically pure dipeptide. The unreacted carboxyl component isolated from the reaction mixture, preserves full initial optical activity just as in the case of mixed anhydrides.

The experimental data obtained by mixed anhydride and DCC activation of the carboxyl group, demonstrate that racemization does not occur. The formation of an azlactone from mixed anhydride **(19)** or from the activated compound **(21)** is probably hindered by a steric effect, owing to the presence of the two bulky methyl groups in the proximity of the reaction center. Consequently, the intramolecular attack of the carbonyl oxygen on the activated carboxyl group from **(19)** and **(21)**, in order to form azlactone, hardly occurs or is even prevented. In the case of acid chloride the steric effect of the two methyl groups is not detectable, on account of the smaller volume of chlorine in relation to the substituents of the activated compounds **(19)** and **(21)**.

The following experimental data also plead to support this explanation. The conversion of acyl-phenylalanine **(10)** into anilide **(24)** by means of the acid chloride, results in the total loss of optical activity, while with mixed anhydride **(19)** optically active **(24)** was obtained.

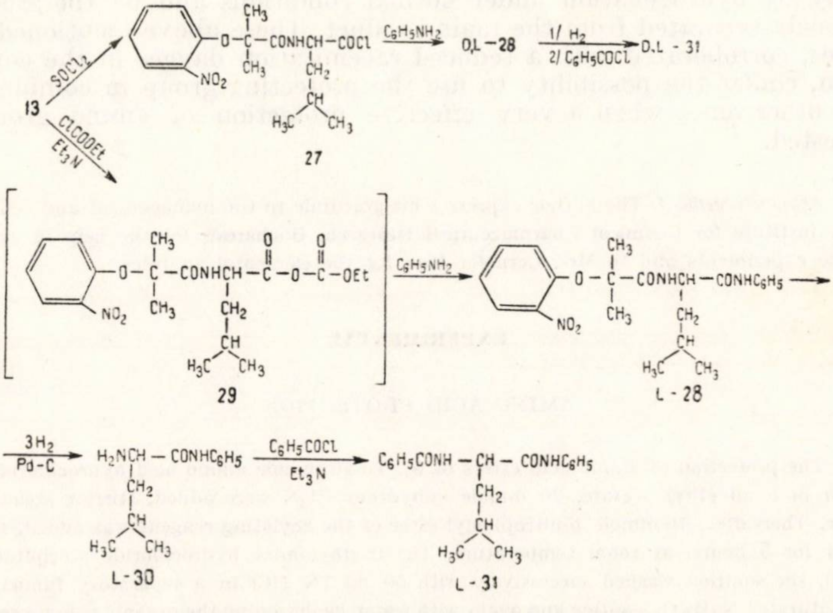
Scheme 3. — Synthesis scheme of phenylalanyl-glycine an d phenylalanyl-anilide.

Phenylalanyl-anilide **(25)** separated after catalytic hydrogenation, has the same optical activity as the optically pure product described in the literature, [8] and the acetylated derivative **(26)** has a greater positive rotation than **(25)**.

Also 2-methyl-2-(*o*-nitrophenoxy)-propionyl-alanyl-L-leucine **(13)** behaves in a similar manner with the protected phenylalanine (see scheme 4). The anilide **(28)** resulted from acid chloride **(27)** is racemic, while the anilide formed *via* mixed anhydride, after deprotecting **(30)** by catalytic reduction and benzoylation, yields benzoyl-L-leucyl-anilide **(31)** having the same optical activity as that described in literature. [13]



Scheme 4. — Leucyl-anilide synthesis scheme.

As may be seen from scheme 3, 2-methyl-2-(*o*-nitrophenoxy)-propionyl-peptide ester **(20)** can be used further in peptide synthesis. The two protecting groups can be selectively eliminated. By base-catalysed hydrolysis, free acid **(22)** results. By catalytical reduction, the protecting group of the amine was eliminated. Reduction time is very short, and as it was demonstrated by the chromatograms at the end of hydrogen adsorption, the protecting group is eliminated fully under the form of 3,3-dimethylbenzomorpholone **(17)**. The separation of the amine component, free from products resulted after protecting group elimination, involves no complication.

From the given data and those described in the experimental part, it can be concluded that the protection of amino groups by the 2-methyl-

2-(*o*-nitrophenoxy)-propionyl residue can find applications in peptide synthesis, having at the same time some peculiarities which could offer advantages in relation to the used reagents and the experimental techniques. The acylation agent is prepared easily, is pure and stable, enables the achievements of high protecting yields, without racemization danger, such as occurs in the case of phthalyl, formyl or trifluoroacetyl groups. The protecting groups confer a better crystallinity to the protected amino acids (especially in comparison to urethanes), stability in acid media and undefined stability. The presence of the nitro group in the peptide molecule enables the determination of very small amounts of products by U.V. absorption at 255 nm. Elimination of the protecting group occurs simply by hydrogenation under normal conditions and by the products are easily separated from the main product. These above mentioned properties, corroborated with a reduced racemization danger in the condensation, confer the possibility to use the protecting group in combination with other ones, when a very effective protection of amino group is requested.

Acknowledgement. The author expresses his gratitude to the management and colleagues of the Institute for Chemical Pharmaceutical Research, Bucharest, for the help in carrying out the experiments and to Mrs. Cornelia Ioan for the elemental analyses.

EXPERIMENTAL

AMINO ACID PROTECTION

The protection of amino acid esters (**3, 5**). To 10 mmole amino acid hydrochloride, suspended in 5 ml ethyl acetate, 20 mmole anhydrous Et_3N were added, stirring steadily for 1 hour. Thereafter, 10 mmole *p*-nitrophenyl ester of the acylating reagent was added, stirring further for 5 hours, at room temperature. The triethylamine hydrochloride precipitate was filtered, the solution washed successively with 50 ml 1N HCl in a separatory funnel, then with saturated $NaHCO_3$ solution and again with water, maintaining the organic volume constant by fresh solvent addition. After drying the solution on anh. Na_2SO_4, the solvent was removed in vacuum and the residue recrystallized from an adequate solvent.

Saponification of the protected amino acid ester (**3**). To the solution of 10 mmole N-protected amino acid ester in 30–50 ml *t*-butanol, 15 mmole aqueous solution of 2N NaOH was added, stirring for 2–3 hours, at room temperature. After complete hydrolysis, that can be controlled by TLC on silica plates, 40 ml water was added and the solvent removed in vacuum, with a rotatory evaporator. The residue solved in 40 ml water, acidulated to pH = 6 and the unreacted product was extracted with ethyl ether. The ice-cooled aqueous solution was acidulated to pH = 2, when the N-protected amino acid separated, filtered, dried and recrystallized from an adequate solvent.

Amino acid acylation (**4, 8, 9–13**). To the solution of 25 mmole $KHCO_3$ in 15 ml water and 10 mmole amino acid, a solution of 10 mmole *p*-nitrophenyl ester of the acylating agent in 10 mmole acetone was added under stirring. Several times, some part of the acylating agent precipitated, but by prolonging its stirring at room temperature for 2 hours, a homogeneous solution was obtained. The mixture was heated to reflux for 2–4 hours controlling the disappearance of free amino acid on silica plates. Eluent- benzol : acetone : acetic acid (60 : 35 : 5 in volume); free amino acid was evidenced by means of ninhydrine solution.

Acetone was removed in vacuum, the residue dissolved in 70 ml distilled water, acidulated to pH = 6, and *p*-nitrophenol and the unreacted ester were extracted 3 times with 15 ml ethyl acetate. Solvent traces were eliminated in vacuum from the aqueous solution, and N-acylated amino acid was precipitated, from the ice-cooled solution with HCl 10%, until pH = 2. When the amino acid did not crystallize satisfactorily, the sedimented oil was extracted with ethyl acetate and, after drying and solvent removal, it was recrystallized from a suitable solvent.

Lysine diacylation (**6**,**7**). To the solution of 10 mmole lysine base in 15 ml 1 molar $NaHCO_3$, 20 mmole *p*-nitrophenyl ester of the acylating acid, dissolved in 40 ml acetone, was added. The mixture heated for 3 hours to reflux on a water bath, provided a homogeneous solution. With TLC (on silica with sec$-$BuOH : HCOOH : H_2O = 75 : 15 : 10) a prelevated sample indicated the full reaction of lysine into the diacylated derivative and a small amount of N^{ε}-acylated derivative.

The solvent was removed in vacuum, the residue dissolved in 30 ml water, treated with HCl 10% to pH = 6 and the resulted *p*-nitrophenol has been extracted with ethyl acetate. To the 0° cooled aqueous solution HCl was added till pH = 1, when the diacylated product precipitated. For the removal of lysine and monoacylated derivative traces, the precipitate was extracted with 2 portions of 25 ml dichloromethane, the unified extracts were washed successively with 20 ml 2N HCl and water. The solution was dried over Na_2SO_4 and after solvent removal in vacuum, the residue was recrystallized from the solvent mentioned in table 1.

THE ELIMINATION OF PROTECTING GROUPS FROM AMINO ACIDS

To the Pd$-$C 5% (0.5 g) catalyst in 10 ml glacial acetic acid, previously hydrogenated, [3] 1 mmole protected amino acid, solved in 10 ml glacial acetic acid, was added. The theoretical amount of hydrogen was absorbed in 10$-$30 minutes, thereafter absorption stopped. Reduction and cleavage processes of the protecting groups were controlled with TLC (on silica G plates, by means of the solvent system sec-BuOH : H_2O : HCOOH = 75 : 10 : 15, and iodine vapour colouring or ninhydrine solution).

The catalyst filtered on a cellite layer was washed with acetic acid. The solution was concentrated in vacuum, eliminating acetic acid in an advanced manner by adding water to the residue and evaporating. The residue was treated with 5 ml water, 1 mmole HCl, and the resulting lactam separated by filtering. For full elimination of the cyclized product, the aqueous solution was extracted by ethyl ether, and processed in order to separate the free amino acid.

For the separation of monoamino-monocarboxyl acids, the solution was neutralized to pH = 6, when the amino acid crystallized. Concerning lysine, the monohydrochloride solution was concentrated to a small volume, and precipitated with alcohol or acetone. The deprotection yield is quantitative. The separated amino acids have equal specific rotation values to the initial ones. The lactams separated by cyclization do not colour with a solution of FCl_3 5% (N-hydroxy-lactams are absent) and do not depress the melting point, in a mixture with authentic products. [3]

SYNTHESIS OF THE PEPTIDE BOND AND ANILIDES; CONTROL OF RACEMIZATION

2-*Methyl*-2-(*o-nitrophenoxy*)-*propionyl-D,L-phenylalanyl-ethyl glycinate* (*D,L*-**24**)

i. To 3.72 g (10 mmole) protected L-phenylalanine (**10**) dissolved in 50 ml anhydrous benzol, 1.45 ml (20 mmole) $SOCl_2$ was added, and refluxed 2 hours on a water bath. The excesses of $SOCl_2$ and solvent were removed in vacuum, while the residue was solved in 50 ml anhydrous benzol.

To a suspension of 5.6 g (40 mmole) glycine ethyl ester hydrochloride acid in 50 ml chloroform, a KOH solution (3.5 g in 3.5 ml water) was added under very strong stirring. To the separated chloroformic layer, dried over anh. K_2CO_3, filtered and cooled to $-10°$, the solution of acid chloride in benzene was added under stirring. The mixture was kept for 2 hours at room temperature, washed successively with 30 ml solution of HCl 5%, water, saturated $NaHCO_3$ solution and again water. By acidifying the aqueous bicarbonate solution previously resulted, 0.18 g acyl-phenylalanine (m.p. 147–149°) was separated. After recrystallization from water-alcohol (m.p. 150–151°), it was similar to the racemic product of acylated phenylalanine (**9**). *Calcd.* : $C_{19}H_{20}N_2O_6$, C : 61.25 ; H : 5.51 ; N : 7.52 ; *Found* : C : 61.20 ; H : 5.42 ; N : 7.45%. $(\alpha)_D^{25} = 0$.

The organic solution was dried over anh. Na_2SO_4, the solvent removed in vacuum and the residue mixed with 10 ml anh. Et_2O and let to crystallize at cool. By filtering, 4.03 g D,L-**24**) m.p. 130–133°) were separated, in 88% yield. After recrystallization from abs. methanol, (m.p. 134–135.5° ; $(\alpha)_D^{25} = 0$ (c = 2, MeOH abs.) *Calcd.* : $C_{23}H_{27}N_3O_7$, C : 60.38 ; H : 5.94 ; N : 9.18 ; *Found* : C : 60.6 ; H : 5.98 ; N : 9.20%.

The product synthetized from (**9**) and ethyl glycinate has the same properties.

2-*Methyl*-2-(*o-nitrophenoxy*)-*propionyl-L-phenylalanyl-ethyl glycinate* (L-**24**).

ii. (*via* N,N′-Dicyclohexyl carbodiimide ; DCC)

To the solution of 3.72 g (10 mmole) (**10**) in 20 ml anhydrous dioxane and 20 ml dichloromethane, 1.03 g (10 mmole) freshly distilled ethyl glycinate was added, cooled to $-10-15°$. Under energetic stirring, 2.06 g (10 mmole) DCC, solved in 10 ml dichloromethane, was added dropwise, stirring further for 2 hours permitting temperature to increase until room temperature. After standing over night, one drop of glacial acetic acid was added, stirred for an hour, the resulted dicyclohexylurea filtered, and washed with dioxan. The solution was evaporated and the crystalline residue was dissolved in 150 ml dichloromethane. It was successively washed with 50 ml HCl 5%, water, saturated $NaHCO_3$ solution, again with water and then dried on anh. Na_2SO_4. Acidulating the aqueous $NaHCO_3$ solution, 0.13 g (**10**) were recovered, m.p. 132–134°.

The drying agent was eliminated by filtering, the solvent removed and the residue recrystallized in 12 ml absolute methanol. 3.97 g (**24**) crystalline, white product was achieved, with m.p. 138° (87% yield) ; $(\alpha)_D^{25} = -22$ (c = 2.29, absolute methanol). *Calcd.* : $C_{23}H_{27}N_3O_7$, C : 60.38 ; H : 5.94 ; N : 9.18 ; *Found* : C : 60.6 ; H : 6.10 ; N : 9.12%.

The experiment repeated with greater amounts of reagents yielded 98% of the theory.

iii. (*via* Mixed anhydride method)

To the solution of 3.72 g (10 mmole) (**10**) in 10 ml purified dichloromethane, 1.4 ml (10 mmole) anh., freshly distilled Et_3N were added. Cooled to $-15°$, 0.95 ml (10 mmole) freshly distilled ClCOOEt, dissolved in 3 ml dichloromethane were added dropwise, under stirring. After 15 min, 1.03 g (10 mmole) freshly distilled ethyl glycinate, solved in 30 ml dichloromethane were added, stirred at low temperature for 30 min and post-reacted for 2 hours at room temperature. The reaction mixture was washed successively with 30 ml HCl 5% solution, water, saturated $NaHCO_3$ solution and again with water. By acidulating the $NaHCO_3$ solution, 0.6 g 2-methyl-2-(*o*-nitrophenoxy)-propionyl-L-phenylalanine (**10**) with m.p. 130–134°, were recovered.

After drying the solution over Na_2SO_4, the solvent was removed in vacuum, the residue mixed with 10 ml absolute Et_2O, and put to crystallize at cool. After filtering, 2.35 g (L **20**) m.p. 135–137° were obtained, that increased to 138° when recrystallized from absolute methanol; 65% yield. *Calcd.* : $C_{23}H_{27}N_3O_7$, C : 60.38 ; H : 5.94 ; N : 9.18 ; *Found* : C : 60.4 ; H : 6.00 ; N : 9.14%. $(\alpha)_D^{25} = 21.8$ (c = 2, absolute methanol).

2-*Methyl*-2-(*o-nitrophenoxy*)-*propionyl-L-phenylalanyl-glycine* (**22**)

To a suspension of 4.72 g (**20**) (10.32 mmole) in 110 ml *t*-butyl alcohol, 10 ml 2N NaOH were added. A yellow homogeneous solution was obtained after stirring for 1 hour. It was stirred in addition for 2 hours, added 150 ml water, and the solvent removed in vacuum, by a rotatory evaporator. The residue was solved in 100 ml water, acidulated to pH = 6, and the traces of unreacted products were extracted 3 times with 20 ml Et_2O.

The solvent traces were eliminated from the aqueous solution, and after cooling to 0°, acidifying to pH = 2, a yellow product, crystallizing in time, was achieved. After filtering in vacuum, drying over P_2O_5, 4 g (**22**) m.p. 110–112° and $(\alpha)_D^{25} = -212$ (c = 2, abs. methanol) were achieved. Yield-90%. Through recrystallization with abs. methanol-ether 1:1, the melting point increases to 124–126° and $(\alpha)_D^{25} = -282$. *Calcd.* : $C_{21}H_{23}N_3O_7$, C : 58.73 ; H : 5.39 ; N : 9.78 ; *Found* : C : 58.70 ; H : 5.80 ; N : 9.68%.

L-Phenylalanyl-glycine (**23**)

To a suspension of 1.5 g g Pd–C 5% catalyst in 20 ml acetic acid hydrogenated at room temperature, 1.24 g (2.84 mmole) 2-methyl-2-(*o*-nitrophenoxy)-propionyl-L-phenylalanyl-glycine (**22**) solved in 20 ml acetic acid was added and the reduction was continued. Hydrogen absorption stopped after 30 min, while TLC (on silica G plates, with $C_6H_6 : CH_3COCH_3 : CH_3COOH = 60 : 35 : 5$) indicates the full cleavage of the protecting group. The free peptide remains at start, while the initial product has Rf = 0.5 (colouring with iodine and ninhydrine solution). Samples do not give positive reaction with $FeCl_3$ 5% solution and neither on diazotization and coupling with β-naphthol.

The catalyst was filtered on a cellite layer, and the solvent removed in vacuum. To the oil-like residue, 3 ml 1N HCl solution and 5 ml water were added; 0.5 g 3,3-dimethylbenzmorpholone was separated by filtering. The aqueous solution was 3 times extracted with 20 ml Et_2O in order to eliminate the cyclized product traces and concentrated in vacuum. The residue was solved with 5 ml water, neutralized with a solution of Et_3N 5% to pH = 6 and concentrated in vacuum. The residue was triturated with 15 ml acetone, and the free peptide filtered. In order to remove triethyl amine hydrochloride, the precipitate was refluxed with 10 ml chloroform, yielding 0.62 g L-phenylalanyl-glycine, m.p. 250–252° (decomposition). Crystalline product was obtained after recrystallization from water-acetone and dried over P_2O_5, m.p. 258–260° (decomposition). $(\alpha)_D^{25} = 93$ (c = 2, water). *Calcd.* : $C_{11}H_{14}N_2O_3$ 1/2 H_2O, C : 57.12 ; H : 6.54 ; N : 12.1 ; *Found* : C :. 57.20 ; H : 6.70 ; N : 12.17%.

2-*Methyl*-2-(*o-nitrophenoxy*)-*propionyl-D,L-phenylalanyl-anilide* (D, L-**24**)

To the solution of 1.20 g (3.22 mmole) 2-methyl-2-(*o*-nitro-phenoxy)-propionyl-L-phenylalanine (**10**) in 16 ml anh. benzene, heated to reflux on a water bath, 0.8 g (6.72 mmole) $SOCl_2$ were added. The solvent and $SOCl_2$ excess were removed in vacuum after 2 hours, and the residue solved with 20 ml anh. benzene. To the ice-cooled solution of 0.30 ml (3.22 mmole) aniline and 0.46 ml (3.22 mmole) triethylamine in 20 ml benzene, a solution of benzene-acid chloride was added. It was kept over night and washed successively with 20 ml water, 2N HCl saturated $NaHCO_3$ solution and again with water. After drying over natrium sulphate, the benzene solution was concentrated to sicc., while the oil-like residue, recrystallized from acetic acid, yielded 0.91 g white crystalline D,L anilide (**24**), m.p. 158—159°, soluble in Et_2O, insoluble in petroleum ether; $(\alpha)_D^{25} = 0$ (c = 2, abs. methanol); *Calcd.*: $C_{25}H_{25}N_3O_5$, C: 67.09; H:5.63; N: 9.39; *Found*: C: 67.10; H: 5.70; N: 9.50%.

2-Methyl-2-(o-nitrophenoxy)-propionyl-L-phenylalanyl-anilide (L-**24**)

To the solution of 3.72 g (**10**) (10 mmole) in 40 ml dichloromethane, 1.4 ml (10 mmole) Et_3N was added, cooling at —15° with ice and salt. 0.95 ml (10 mmole) ClCOOEt, solved in 10 ml dichloromethane were dropped, stirred for 30 min at low temperature, and 1 ml (11 mmole) aniline dissolved in 10 ml dichloromethane was added. It was stirred for 1 hour at low temperature and kept over night, at room temperature.

The reaction mixture was thoroughly washed successively with 20 ml HCl 10% water, saturated $NaHCO_3$ solution, and again with water. Acidulating the aqueous bicarbonate solution, 2.12 g unreacted (**10**) crystallized. After drying the organic solution over anh. Na_2SO_4 and solvent removal in vacuum, 2 g white, crystalline anilide (L **24**), m.p. 138—140° was obtained. The yield is quantitative, considering the recovered product (**10**) too. After recrystallization from EtOH and drying over P_2O_5, m.p. 142°; $(\alpha)_D^{25} = -18.5$ (c = 1.85, abs. methanol). *Calcd.*: $C_{25}H_{25}N_3O_5$, C: 67.05; H: 5.65; N: 9.39; *Found*: C:67.00; H:5.80; N: 9.25%.

L-Phenylalanyl-anilide (**25**)

After catalytical reductive removal of the protecting group of (**24**) under standard conditions, L-phenylalanyl-anilide had close properties to those described in literature,[8] m.p. 70—73°; $(\alpha)_D^{25} = 18.5$ (c = 1.85, absolute methanol).

N-acetyl-L-phenylalanyl-anilide (L **26**)

To the solution of 0.24 g (1 mmole) L-phenylalanyl-anilide (**25**) in 10 ml 1N HCl, 1 ml saturated $NaHCO_3$ solution and 1 ml Ac_2O were added. After 30 min, 1 ml Ac_2O was still added, heated to boiling, and acetic acid added until a clear solution was obtained. After cooling, 0.25 g (**26**) crystallized, m.p. 193—195°, in 88.5% yield. Recrystallized from abs. methanol, m.p. increased to 195—196°. $(\alpha)_D^{25} = 33.5$ (c = 2.7, glacial acetic acid). *Calcd.*: $C_{17}H_{18}N_2O_2$, C:71.30; H: 6.33; N: 9.78; *Found*: C:71.20; H: 6.40; N: 9.50%.

2-*Methyl*-2-(*o-nitrophenoxy*)-*propionyl-D,L-leucyl-anilide* (D,L-**28**)

Starting from the acylated L-leucine (**13**) derivative, by acid chloride conversion (**27**), as described at the suitable product of L-phenylalanine (**24**), the racemized anilide was obtained, m.p. 140—144°, in 77% yield. The melting point remains unchanged, after recrystallization from ethyl alcohol. $(\alpha)_D^{25} = 0$ (c = 2, abs. methanol) *Calcd.*: $C_{22}H_{27}N_3O_7$, C: 63.9; H: 6.58; N: 10.16; *Found*: C: 64.20; H: 6.80; N: 10.30%.

N-Benzoyl-D,L-leucyl-anilide (D,L-**31**)

To a suspension of 1 g Pd—C 5% in 20 ml acetic acid, previously hydrogenated, the solution of 1.25 g (3 mmole) (D,L **28**) in 20 ml glacial acetic acid was added. After the absorption of the theoretical hydrogen amount (205 ml), the catalyst was filtered on a cellite layer and washed with acetic acid. TLC (on silica G with chloroform : ethyl acetate = 4:1, iodine vapour and ninhydrine colouring) evidenced the total disappearance of the initial product (Rf = 0.7), the deprotected product appeared at start while 3,3-dimethyl-benzmorpholone at Rf = 0.77.

To the filtered solution, 3.2 ml HCl 1N and 5 ml water were added, and acetic acid was removed in vacuum. The residue resolved with 5 ml water, separated 0.5 g 3,3-dimethyl-benzmorpholone after filtering m.p. 165—167°, while the solution did not yield positive $FeCl_3$ reaction, thus not containing N-hydroxy-lactam.

The aqueous solution was concentrated to sicc in vacuum, dried over P_2O_5, yielding 0.72 g leucyl-anilide hydrochloride, very deliquescent, in 100% yield. The product was solved with 15 ml water, neutralized with 2N NaOH, pH = 9—10, and the base extracted 3 times with 15 ml Et_2O. After drying the ethereal solutions over anh. Na_2SO_4, it was treated with 1 ml Et_3N, ice-cooled, and to this added 0.5 ml anh. benzoyl chloride. Finally, 0.57 g, white, crystalline N-benzoyl-D,L-leucyl-anilide, m.p. 179—180°, was obtained; melting point 196°, after recrystallization from ethyl alcohol. *Calcd.* : $C_{19}H_{22}N_2O_5$, C : 73.52 ; H : 7.14 ; N : 9.02 ; *Found* : C : 73.70 ; H : 7.30 ; N : 9.05 %.

2-Methyl-2-(o-nitrophenoxy)-propionyl-L-leucyl-anilide (L-**28**)

The synthesis procedure was similar to that adopted for L-phenylalanyl-anilide (L-**24**), *via* mixed anhydride, in a 70.5 % yield ; a white product resulted when crystallized from ethyl alcohol. M.p. 127—128°. $(\alpha)_D^{25} = -13$. (c = 1.5, abs. methanol). *Calcd.* : $C_{22}H_{27}N_3O_5$, C : 63.90 ; H : 6.58 ; N : 10.16 ; *Found* : C : 64.00 ; H : 6.70 ; N : 10.25 %.

N-Benzoyl-L-leucyl-anilide (L-**31**)

Deprotection and benzoylation of product (L-**28**) were executed similarly to the racemized product. Melting point 214—215°. $(\alpha)_D^{25} = 10.75$ (c = 1.5, glacial acetic acid), after recrystallization from ethanol. *Calcd.* : $C_{19}H_{22}N_2O_2$, C : 73.52 ; H : 7.14 ; N : 9.02 ; *Found* : C : 73.60 ; H : 7.20 ; N : 9.05 %.

Revue Roumaine de Chimie, 18, 3, 463 – 468 (1973)

AN IMPROVED SYNTHESIS OF OPTICALLY PURE N^{α}-METHYL-LYSINE

FLAVIAN CUIBAN

Department of Industrial Chemistry, Polytechnical Institute "Traian Vuia"
Timişoara, POB 103, Romania

Received October 27, 1972

A procedure for the selective protection of the terminal amino group of lysine by acylation with 2-methyl-2-(*o*-nitrophenoxy)-propionic acid was established, which permitted the synthesis of N^{α}-methyl-L-lysine.

The discovery of numerous N-methylated amino acids in peptide antibiotics isolated from microorganisms, stimulated the study of synthetical obtention of N-methyl-amino acids. Amino acid methylation, preserving the optical purity, was reported recently [1]. In the case of amino acids such as lysine which also possess another amino function, susceptible to be methylated, it was proposed [1] to protect it by means of the benzyloxycarbonyl group, frequently used in peptide syntheses. The above authors found however the partial cleavage of the protecting group during the synthesis and the appearance of secondary products difficult to eliminate.

Considering the high stability and easy removal of a new protecting group tested in peptide synthesis, [2] it appeared interesting to use it in the synthesis of N^{α}-methyl-lysine (**1**). As it is known, the nitro group is not reduced by some complex hydrides. [3] Therefore, we protected the lysine terminal amine by acylation with 2-methyl-2-(*o*-nitrophenoxy)-propionic acid. The succession of reactions in N^{α}-methyl-lysine synthesis is indicated in scheme 1.

In the reductive methylation of compound (**4**) there is no danger of splitting the protecting group, while by its elimination from compound (**5**) the N^{α}-benzyl residue is also eliminated.

Some difficulties were encountered in the synthesis of compound (**2**), the N^{ε}-acylated derivative of lysine. Although it was affirmed [4] that lysine can be acylated selectively at the terminal amine by means of

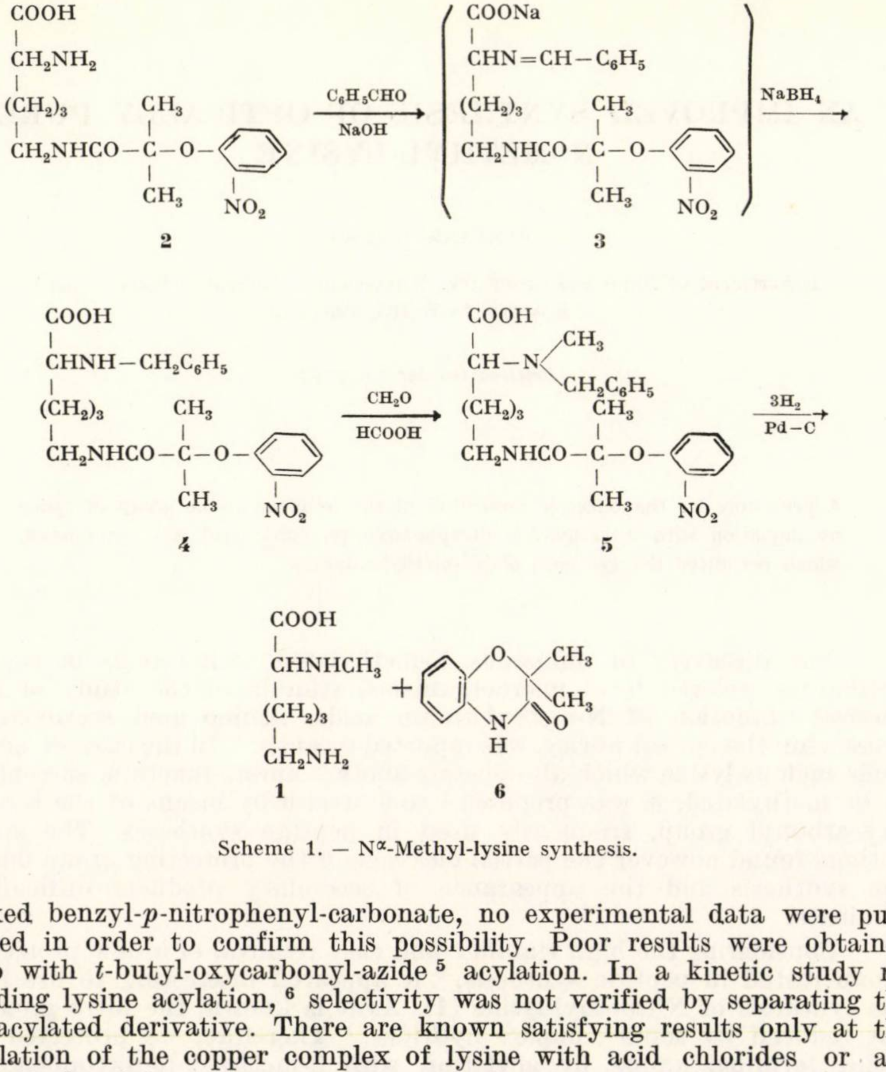

Scheme 1. — N^{α}-Methyl-lysine synthesis.

mixed benzyl-*p*-nitrophenyl-carbonate, no experimental data were published in order to confirm this possibility. Poor results were obtained also with *t*-butyl-oxycarbonyl-azide [5] acylation. In a kinetic study regarding lysine acylation, [6] selectivity was not verified by separating the N^{ε}-acylated derivative. There are known satisfying results only at the acylation of the copper complex of lysine with acid chlorides or anhydrides[7] and thus our experiments were directed especially towards these methods.

Similarly to the preparation of acylamino acids, from the previous work, [2] 2-methyl-2-(*o*-nitrophenoxy)-propionic acid chloride could not be used, on account of the competitive hydrolysis with the acylation reaction. The acylation experiments of lysine copper complex with mixed anhydride **(7)** (see scheme 2), prepared after standard techniques *in situ*, conducted to important amounts of N^{ε}-ethyl-oxycarbonyl-lysine (**8**), along with the N^{ε}-acylated derivative (**2**).

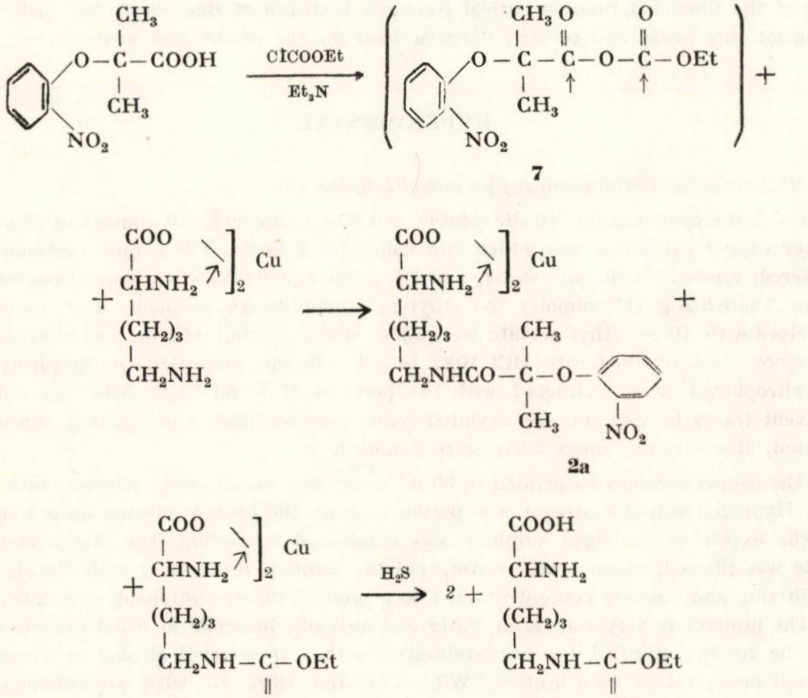
The N$^{\varepsilon}$-ethyl-carbamate (**8**) was separated by repeated recrystallizations and was identical to the product synthetized by the acylation of lysine copper-complex.

The amount of urethane (**8**) varies from 15 to 50% depending on the experimental conditions. Although both products (**2** and **8**) were evidenced chromatographically in the cupric complex stage (**2a** and **8a**), their separation for preparative goals did not succeed.

The occurrence of urethane (**8**) in the reaction mixture is due to the nonselective attack of the terminal lysine amine on the mixed anhydride (**7**), owing probably to the steric hindrance and to the structure of the copper complex of lysine.



Scheme 2. — N$^{\varepsilon}$-2-Methyl-2-(*o*-nitrophenoxy)-propionyl-lysine synthesis *via* mixed anhydride

The complex of lysine can be acylated with satisfactory results by means of the 2-methyl-2-(*o*-nitrophenoxy)-propionic acid *p*-nitrophenyl ester. The complex reaction product incorporated the copper lysine complex and the cupric salt of the 2-methyl-2-(*o* nitrophenoxy)-propionic acid as impurities from the ester hydrolysis.

However, it is possible, by using *p*-nitrophenyl ester, to acylate predominantly the terminal amine even from the uncomplexed lysine.

It is necessary then to use lysine in excess and, for pure product separation, to resort to ion exchange chromatography. The yield is only 40% in the latter case (for details, see experimental part).

The course of the synthesis after reaction scheme 1 does not encounter difficulties. Very good yields were met at every stage, and N^{α}-methyl-lysine had a slightly higher melting point and specific rotation than those described in the literature.[1] The established procedure can be applied for both enantiomers and may be extended to other diamino acids.

Acknowledgement. The author expresses his gratitude to the management and colleagues of the Chemical Pharmaceutical Research Institute of Bucharest, for their help in carrying out this work, and to Mrs. Cornelia Ioan for the combustion analyses.

EXPERIMENTAL

N^{ε}-2-methyl-2-(o-nitrophenoxy)-propionyl-L-lysine (**2**)

i — Via copper complex. To the solution of 1.62 g lysine 90% (10 mmole) in 25 ml water, 2 g basic copper carbonate was added and boiled for 2 hours. The copper carbonate excess was filtered, washed with hot water, and 2.5 g (30 mmole) $NaNCO_3$ were dissolved in the solution. There 5.2 g (15 mmole) 2-methyl-2-(*o*-nitrophenoxy)-propionic acid *p*-nitrophenyl ester, solved with 10 ml ethyl acetate were added under stirring. Stirring was continued for 12 hours more, then acidified with HCl 10% to pH = 6, the unreacted *p*-nitrophenyl ester and *p*-nitrophenol were extracted with two portions of 50 ml Et_2O. After the removal of the solvent traces in vacuum, the acylated lysine complex (**2a**) was filtered, washed with water and, after drying, about 2.5 g were obtained.

The copper-complex suspended in 30 ml water was solved under stirring, with 0.35 ml H_2SO_4. Hydrogen sulphide stream was passed through the heated solution on a water bath, while the excess of hydrogen sulphide was eliminated by boiling. The precipitated copper sulphide was filtered, washed with water, and the solution neutralized with $BaCO_3$ powder. After filtering and vacuum concentration, 1.76 g product (**2**) was obtained, m.p. 205°, in 50% yield. The product is very soluble in water and alcohols, insoluble in usual organic solvents. It can be further purified by recrystallization either from ethyl alcohol or by solving in water and precipitation from acetone. With TLC (on silica G, with sec-butanol : formic acid : water = 75 : 15 : 10), it was unitary chromatographical, Rf = 0.58; $\varepsilon = (255\ \mathrm{nm})\ 2.68 \cdot 10^3$ in glacial acetic acid, which permitted quantitative determination. $(\alpha)_D^{25} = 9$ (c = 1.25 in 2N HCl). *Calcd*: $C_{16}H_{23}N_3O_6$, C : 54.38; H : 6.56; N : 11.89.

Found: C : 54.20; H : 6.70; N : 11.90%.

ii — Direct acylation. To a solution of 20 mmole lysine in 12 ml water, 10 mmole 2-methyl-2-(*o*-nitrophenoxy)-propionic acid *p*-nitrophenyl ester, dissolved with 40 ml acetone, were added under stirring. Stirring was continued at room temperature for 8 hours. After heating and refluxing for 3 hours more on water bath, the solvent was removed by means of a rotatory evaporator. The residue dissolved in 50 ml water, acidulated with HCl, pH = 6, then *p*-nitrophenol and the unreacted ester were extracted successively with 20 ml ethyl acetate. To the aqueous solution 20 mmole HCl solution was added, while the precipitated N-diacylated lysine derivative was separated either by filtering, or extraction by means of ethyl acetate or ethyl ether.

The aqueous solution removed from solvent traces was passed over a strong acid cationite column (Dowex 50 or Zerolit 225) 1.5 × 15 cm. Initially, the column was washed with water up to the elimination of chlorine ions from the eluate, then with 1 % ammonia solution, collecting the pH = 5—11 fraction, which gave positive reaction with ninhydrine soaked paper. The collected fraction was concentrated in vacuum for ammonia removal and passed over a weak cationite acid column of carboxyl type (Amberlite IRC 50), with close sizes to the fist cationite column. The column was eluted by aqueous ammonia solutions of increasing concentrations, 0.25, 0.5.1 %, then the pH = 4.5—7.5 fraction collected, which gave positive ninhydrine reaction and contained the N^{ε}-acylated derivative of lysine. The almost pure product was achieved by vacuum concentration to sicc. The fraction collected further at pH = 7—11, contained unreacted lysine and small quantities of N^{ε}-acylated derivative. It can be introduced into a new reaction.

iii — Mixed anhydride acylation (**7**). Usual techniques were performed for anhydride preparation, with tetrahydrofurane as solvent. The precipitated complex contained both products (**2a** and **8a**), while the urethane *ratio* was greater with increasing tetrahydrofuran concentration. The composition of the mixture was established by UV spectroscopy of N^{ε}-[2-methyl-2-(*o*-nitrophenoxy)-propionyl]-lysine. The urethane separation could be achieved only after hydrogenation of the mitxure in order to eliminate the protective group from (**2**), which was subsequently separated of the resulting lysine, by ion exchange chromatography, as described at *ii*.

N^{ε}-*Ethyloxycarbonyl-L-lysine* (**8**). To the solution of 5.90 g lysine 90 % base (36.4 mmole) in 100 ml water, 15 ml 2N HCl and 9 g basic copper carbonate were added, and boiled under stirring for 2 hours. After filtering the copper carbonate excess and adjusting to pH = 9 with 2N natrium hydroxide solution, cooled to 5°, and 5.92 g (54.5 mmole) ClCOOEt was added dropwise under stirring, adding in the meantime hydroxide for constant pH. The precipitate was filtered, washed with water and ethyl alcohol, yielding after drying 9.3 g cupric complex (**8a**), m.p. 252° (decomposition). The precipitate suspended in 200 ml water, was treated by hydrogen sulphide stream, at boiling on water bath, hot filtered and let to crystallize after cooling. After concentrating the mother solution, altogether 6.7 g, in 80 % yield, a white, crystalline product was obtained; m.p. 264° (decomposition), chromatographical unitary (on silica G plates, with sec-butanol : formic acid : water = 75 : 15 : 10, Rf = 0,48), $(\alpha)_D^{25} = 16.5$ (c= 1.58 in 2N HCl). *Calcd* : $C_9H_{18}N_2O_4$, C : 49.52 ; H : 8.3 ; N : 12.83 ; *Found* : C : 49.80 ; H : 8.50 ; N : 12.80 %.

N^{α}-*Benzyl*-N^{α}-*[2-methyl-2-(*o*-nitrophenoxy)-propionyl]-L-lysine* (**4**)

To the solution of 2.74 g (7.75 mmole) (**2**) solved with 20 ml water, 4 ml solution of 2N NaOH was added, then dropping under vigorous stirring 0.8 ml (8 mmole) freshly distilled benzaldehyde. To the cleared solution, 1 g $NaBH_4$ solved with 4 ml ice cooled water was added in portions. Stirring was continued for some hours, then benzaldehyde and $NaBH_4$ treatment repeated, with the same amounts. After stirring for 5 hours, hydrochloric acid was added dropwise, very slowly, as to reach pH = 8. The separated precipitate from (**4**) was water washed, the mother solution and water extracted 3 times by 10 ml Et_2O to eliminate benzaldehyde and benzyl alcohol. From the aqueous solution acidified to pH = 6, another amount of (**4**) precipitated, altogether 2.3 g, in 67 % yield. Recrystallized from ethyl alcohol, in diluted acids and alkalis soluble yellow crystals were obtained, m.p. 210—212°. $(\alpha)_D^{25} = 13.2$ (*c* = 1.6, in acetic acid : 1N HCl, 1 : 1). With TLC (on silica G, with sec-butanol : formic acid : water = 75 : 15 : 10), it appeared unitary with Rf = 0.7, while with iso-BuOH : NH_3 10 % = 85 : 15, Rf = 0.43. It was very poorly coloured with ninbydrine. By successive spraying with a 10 % solution of *p*-nitrobenzoic acid chloride in petroleum ether and pyridine, the plates were coloured blue. *Calcd.* : $C_{23}H_{29}N_3O_6$, C : 62.28 ; H : 6.58 ; N : 9.48 ; *Found* : C : 64.20 ; H : 6.70 ; N : 9.40 %.

N^{α}-(Methyl, benzyl), N^{ε}-[2-methyl-2-(o-nitrophenoxy)-propionyl]-L-lysine (**5**)

To the solution of 1.1 g (2.5 mmole) (**4**) in 4 ml 98 % formic acid, 0.25 ml (3 mmole) 40 % formol solution was added, then heated on water bath until CO_2 emission stopped. Formic acid was removed in vacuum, then treated by ethyl alcohol for full formic acid removal. The residue dissolved with ethyl alcohol, precipitated by means of ethyl ether, and filtered rendered 1.05 g yellow crystals of (**5**) m.p. 151°, in 92 % yield. The melting point increased to 155°, after recrystallization from hydroalcoholic mixture (3 : 1) and was unitary chromatographical (on silica G, with sec-BuOH : HCOOH : H_2O = 75 : 15 : 10, iodine vapour colouring), Rf = 0.62. It did not colour with ninhydrine. The product is soluble in dilute solutions of acids and alkalis, insoluble in water. $(\alpha)_D^{25} = 18.8$ (c = 1.6 in 1N HCl : acetic acid 1 : 1). *Calcd.* : $C_{24}H_{31}N_3O_2$, C : 63.00 ; H : 6.83 ; N : 9.18 ; *Found* : C : 63.20 ; H : 7.00 ; N : 9.30 %.

N^{α}-Methyl-L-lysine (**1**)

A suspension of 0.5 g 5 % Pd—C in 10 ml acetic acid was hydrogenated until the hydrogen absorption stopped. To this catalyst, 0.457 (1 mmole) (**5**) solved in 10 ml glacial acetic acid was added and hydrogenation proceeded ; the theoretical amount of hydrogen, 90 ml, was absorbed in 1 hour. After filtering the catalyst, solvent removal in vacuum, 0.5 ml 2N HCl and 5 ml water were added, while the insoluble 3,3-dimethyl-benzmorpholone (**6**) was extracted by Et_2O, in 3 portions.

The aqueous solution concentrated to a small volume, precipitated with 30 ml absolute ethanol, 0.14 g N^{α}-methyl-L-lysine, as monochlorohydride, crystalline product, m.p. 254—257° (decomposition), in quantitative yield. Literature [1] m.p. 250—253°. $(\alpha)_D^{25} = 31$ (c = 1, in 6N HCl). If necessary, it can be recrystallized from an alcohol-acetone mixture. *Calcd.* : $C_7H_{16}N_2O_2 \cdot HCl$, C : 42.74 ; H : 8.71 ; N : 14.24 ; Cl^- : 18.04 ; *Found* : C : 42.80 ; H : 8.75 ; N : 14.30 ; Cl^- : 19.00 %.

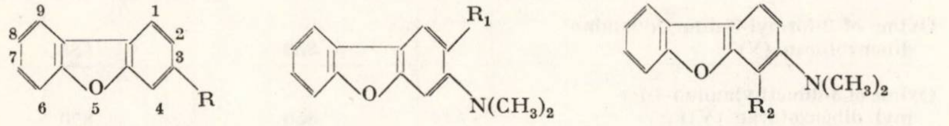
DIBENZOFURANS I. THE FORMYLATION OF 3-DIMETHYLAMINO-DIBENZOFURAN BY THE VILSMEIER-HAACK METHOD

VALER FĂRCĂŞAN and IOAN CRISTEA
Department of Chemistry, University Babeş-Bolyai, Cluj,
str. Arany Janos 11

Received July 31, 1972

By the formylation of 3-dimethylamino-dibenzofuran (I) under the conditions of the Vilsmeier-Haack reaction the aldehydes III and IV were obtained and their structure proved.

There are only few data [1,2,3] concerning the formylation of dibenzofuran derivatives by the Vilsmeier-Haack method [4] and the synthesis of dimethylamino-formyl-dibenzofurans has not been described yet in the literature. These reasons determined us to investigate the behaviour of 3-dimethylamino-dibenzofuran (I) under the conditions of the Vilsmeier-Haack reaction.



I : $R = N(CH_3)_2$ III : $R_1 = CHO$ IV : $R_2 = CHO$

II : $R = H$ V : $R_1 = CHNOH$ VI : $R_2 = CHNOH$

IX : $R = NH_2$ VII : $R_1 = CHN{-}NHC_6H_3(NO_2)_2$ VIII : $R_2 = CHN{-}NHC_6H_3(NO_2)_2$

Compound I was allowed to react with dimethylformamide in the presence of phosphorus oxychloride. From the crude product two compounds, A and B, were isolated by column chromatography (alumina Brockmann III – eluent toluene).

[4] A. Vilsmeier and A. Haack, *Ber. dtsch. chem Ges.*, **60**, 121 (1927).

The bands at 1685 cm^{-1} in the i.r. spectrum as well as the peaks at $\delta = 10.26$ and 10.50 (p.p.m.) in the n.m.r. spectrum indicate the presence of the formyl group. The elemental analyses of these substances, their oximes and 2,4-dinitrophenylhydrazones, show that A and B are isomeric monoformyl derivatives. For the two isomers the structures III and IV are the most probable, taking into account the electrophilic nature of the Vilsmeier-Haack reagents, [5] the electronic effects exerted by the dimethylamino group and the lack of reactivity of dibenzofuran (II) under the conditions used by us for the formylation of 3-dimethylamino-dibenzofuran (I).

The lower melting point and the higher R_f of *A* as compared to *B* suggests a less polar character, which is in better agreement with formula III.

If the i.r. spectra of substances *A* and *B* are compared with those of their oximes (V and VI), 3-dimethylamino-dibenzofuran (I) and dibenzofuran (II), in the range 800 — 900 cm^{-1} (see table 1), a sharp band at 830 cm^{-1} can be observed in the spectra of both *B* and VI, which is absent in the spectra of the other compounds. This band may be assigned to C—H out-of-plane bending of the two adjacent hydrogens in the substituted benzene ring. [6] This can be taken as an argument for the validity of the structure IV assigned to B.

Table 1

IR spectra of I, II, III, IV, V and VI in the range 800 – 900 cm^{-1}

Compound	$1/\lambda\ cm^{-1}$							
Dibenzofuran (II)			846		853			
Diemethylamino-dibenzofuran(I)	818			850				895
2-Formyl-3-dimethylamino-dibenzofuran (III)			840			865	875	
3-Dimethylamino-4-formyl-dibenzofuran (IV)	815	*830*	840			868	888	
Oxime of 2-formyl-3-dimethylamino dibenzofuran (V)				853			885	
Oxime of 3-dimethylamino-4-formyl dibenzofuran (VI)		*828*		850			870	

The n.m.r. spectra are consistent with the formulae III respectively IV for compounds *A* and *B*. Indeed, the aromatic region, in the n.m.r. spectrum of *A*, comprise, apart from the other expected signals, two singlets corresponding to the more shielded 4-proton ($\delta = 7.14$) and the one less shielded in position 1 ($\delta = 8.32$). The same region, in the spectrum of *B*, shows two doublets ($\delta = 7.91$ and 6.96, respectively) determined by the coupling of protons 1 and 2, the last being the more shielded. The coupling constant $J_{12} = 9$ cps, is within the usual range of coupling constants for *ortho* protons in bezene derivatives.[7]

[6] M. AVRAM and GH. D. MATEESCU, "Spectroscopia în infraroşu. Aplicaţii în chimia organică", Editura tehnică, Bucureşti, 1966, p. 272.

The above raported data show that by the formylation of 3-dimethylamino-dibenzofuran (I) two isomeric aldehydes are formed. By comparing the yields (III higher than IV) the preference of the electrophilic reagent in the Vilsmeier-Haack reaction for the position 2 of I is clarely pointed out.

With a view to obtain a deeper insight in the structure of oximes V and VI, we recorded their i.r. spectra. Both compounds show an intense band around 3300 cm^{-1}, due to the associated hydroxyl group. Taking into account the papers of Palmer and Werbin[8] or Hadzi and Premru[9] this fact suggests that the two oximes are in the *sin* (α) form and are associated as dimers.

The hydrogen bonds are stronger in the case of VI (ν_{OH} 3300 cm^{-1}) than in that of V (ν_{OH} 3360 cm^{-1}).

EXPERIMENTAL*

3-Dimethylamino-dibenzofuran (I)

A mixture of 1 g 3-amino-dibenzofuran (IX),[10] 1.75 g sodium bicarbonate, 5 ml water and 1.6 ml dimethyl sulfate were stirred at 10°, until the evolution of carbon dioxide ceased. Then the excess of dimethyl sulfate was decomposed with concentrated ammonia and water. The precipitate was filtered and recrystallized from ethanol. m.p. 96–97°, identical with that one already reported.[11]

Formylation of 3-dimethylamino-dibenzofuran (I)

To a mixture of 1.5 ml ice-cooled DMFA and 0.5 ml phosphorus oxychloride 1 g I was stepwise added. The mixture was warmed on a steam-bath for 2 hours and then poured on 25 g ice.

The pH was adjusted at 6 with a solution of sodium acetate (5 g in 13 ml water) and allowed to stand at room temperature for some hours. The oil which separated was extracted with chloroform. (The mother-liquor was neutralized with sodium bicarbonate and extracted in its turn with chloroform). The chloroform extracts were dried on anhydrous sodium sulfate, and the solvent removed to afford an oil. This was dissolved in toluene and chromatographied on an alumina (Brockmann III) column, using toluen as eluent. Two yellow zones were formed and the two corresponding fractions were evaporated to dryness, yielding the aldehyde *A* (III) (the first which leaves the column) and *B* (IV).

---

* Melting points (uncorrected) were esstimated on Boetius microstage. For recording the i.r. spectra (in KBr pellets), a double-beam Carl-Zeiss Jena UR-20 spectrophotometer was used.
The proton n.m.r. spectra were measured in deuterochloroform (TMS as reference) on a Tesla BS 487 B (80 MHz) apparatus.

CONDENSATION DU 4,4′-AZODIPHÉNOXYDE DE SODIUM AVEC LES DÉRIVÉS CHLOROMÉTHYLÉS DU BENZÈNE

M. IOVU et S. RADU

Faculté de Chimie, Université de Bucarest,
Splaiul Independenţei, 89, Bucarest

Reçu le 22 septembre 1972

La préparation des biséthers par la condensation des phénoxydes de sodium avec les dérivés chlorométhylés en utilisant une nouvelle méthode facile, consistant dans la formation des phénoxydes alcalins anhydres, par l'éloignement de l'eau résultée de la réaction des phénols avec du NaOH, par distillation azéotrope avec un mélange d'éthanol-benzène et puis la réalisation de la réaction de condensation avec le phénoxyde anhydre, toujours en milieu d'éthanol-benzène, nous a conduit à cette étude. La condensation des 4,4-azodiphénoxydes alcalins avec les dérivés chlorométhylés n'est pas décrite dans la littérature. En utilisant la méthode décrite antérieurement on a obtenu le 4,4′-azodiphénoxyde de sodium anhydre qui a été condensé en milieu d'éthanol-benzène avec divers dérivés monochlorométhylés du benzène substitué.

Dans une série d'articles, [1–4] nous avons présenté la synthèse des biséthers avec la formule générale $Ar-O-CH_2-Ar-CH_2-O-Ar$, où le radical aryle représente un noyau benzénique substitué par un ou plusieurs radicaux méthyle, cyclohexyle ou par le groupe nitro.

Ces biséthers ont été synthétisés à l'aide de phénoxydes de sodium anhydres, obtenus par une méthode originale, qui consiste dans l'éloignement de l'eau résultée de la réaction des phénols avec du NaOH, par distillation d'un mélange azéotrope éthanol -benzène -eau, en utilisant un mélange (1 : 1 en volume) d'éthanol-benzène. L'eau a été éloignée par un mélange d'éthanol-benzène qui est aussi indiqué comme milieu de réaction pour la condensation ultérieure du phénoxyde de sodium avec le dérivé chlorométhylé.

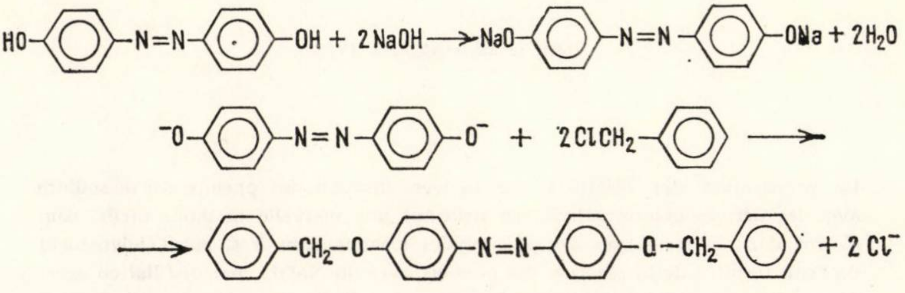
[4] M. Iovu, N. Miclovici et S. Creţu, *Rev. Roumaine Chim.*, **17**, 1417 (1972).

Dans cet article, nous présentons les résultats de la condensation du 4,4'-azodiphénoxyde de sodium avec les dérivés monochlorométhylés suivants : chlorométhyl-benzène, chlorométhyl-2,4-diméthyl-benzène, chlorométhyl-2,5-diméthyl-benzène, chlorométhyl-3,5-diméthyl-benzène, chlorométhyl-2,4,6-triméthyl-benzène et chlorométhyl-4-phényl-benzène.

Le 4,4'-azodiphénoxyde de sodium, anhydre, a été obtenu par traitement du 4,4'-azodiphénol avec l'hydroxyde de sodium (solide) en milieu d'éthanol-benzène et l'éloignement de l'eau sous forme d'un mélange azéotrope eau-éthanol-benzène. Le phénoxyde anhydre est additionné de dérivé chlorométhylé. L'azobisésther résulte par l'action nucléophile de l'anion phénoxydique sur le dérivé chlorométhylé. Les réactions qui ont lieu sont :



L'azobisésther formé précipite avec le chlorure de sodium ; ces composés se séparent des solvants par filtration, puis le chlorure de sodium est éloigné par lavage avec de l'eau, sur le filtre.

L'azobisésther séché est recristallisé à l'aide d'un mélange d'éthanol-benzène (en différents rapports en fonction de la solubilité).

Les conditions de travail sont les mêmes pour tous les composés synthétisés, indifféremment des matières premières.

RÉSULTATS ET DISCUSSION

Les azobisésthers, les résultats de l'analyse élémentaire de C, H, N, leurs températures de fusion et les rendements sont indiqués dans le tableau 1.

Tous ces azobisésthers sont solides, ayant une couleur jaune et fondent à températures élevées (comparativement aux bisésthers synthétisés antérieurement, [1-4] qui ne contiennent pas la fonction azo).

On peut observer dans le tableau 1 que les valeurs des températures de fusion pour les trois isomères : 4,4'-bis (2,4- diméthyl-benzyloxy) azobenzène, 4,4'-bis (2,5-diméthyl-benzyloxy) azobenzène et 4,4'-bis (3,5-diméthyl-benzyloxy) azobenzène sont très proches, les positions des radicaux méthyle sur les noyaux benzéniques influençant très peu les températures de fusion.

Bien que la réaction de condensation du 4,4'-azodiphénoxyde de sodium avec les dérivés chlorométhylés soit totale, les rendements ne sont

pas élevés, parce qu'on a travaillé dans des quantités grandes de solvant, avec des quantités petites de matières premières, en suivant la préparation des produits d'une grande pureté.

L'étude spectrale en IR met en évidence des bandes d'absorption dues aux vibrations caractéristiques des éthers et azodérivés.

Tous les composés présentent une bande d'absorption intense à 1010 + 10 cm^{-1} attribuée à la fréquence symétrique de la liaison C–O–C. Par exemple, pour les composés dont les spectres sont représentés dans la figure 1 on trouve les valeurs suivantes : $\nu C-O-C_{sym} = 1019\ cm^{-1}$ pour le 4,4'-bis(benzyloxy)azobenzène, 1016 cm^{-1} pour le 4,4'-bis(4-méthylbenzyloxy)azobenzène et 1016 cm^{-1} pour le 4,4'-bis(2,5-diméthyl-benzyloxy)azobenzène.

Cette bande se superpose à celle due à $\nu C-H$.

Aussi, tous les azobiséthers absorbent-ils fortement dans la région très étroite autour de la valeur 1150 cm^{-1}, ce qu'on doit aux vibrations asymétriques de la fonction éther. Pour les composés dont les spectres sont réportés dans la figure 1, $\nu C-O-C_{asym}$ a les valeurs suivantes : 1152 cm^{-1} pour le 4,4'-bis(benzyloxy)azobenzène, 1148 cm^{-1} pour le 4,4'-bis(4-méthyl-benzyloxy) azobenzène et 1149 cm^{-1} pour le 4,4'-bis(2,5-diméthyl-benzyloxy)azobenzène.

En comparant les valeurs des longueurs d'onde où absorbent les azobiséthers synthétisés par nous, qui ont un caractère mixte d'éther aliphatique et d'éther aromatique ($-Ar-O-CH_2-Ar$), on constate que celles-ci se trouvent entre les valeurs caractéristiques des éthers

Fig. 1. — Spectres IR des 4,4'-bis(benzyloxy)azobenzène, 4,4'-bis-(4-méthylbenzyloxy)azobenzène et du 4,4'-bis(2,5-diméthylbenzyloxy)azobenzène.

aliphatiques ($\nu_{sym} = 940$ cm^{-1} et $\nu_{asym} = 1070$ à 1050 cm^{-1}) et les valeurs des éthers aromatiques ($\nu_{sym} = 1040$ à 1020 cm^{-1} et $\nu_{asym} = 1250$ cm^{-1}).

Dans les spectres IR est présente une bande de 1410 à 1408 cm^{-1}, de faible intensité, pouvant être attribuée aux liaisons N=N, en accord avec des données de Fatiadi.[5] La seconde bande qui selon l'auteur mentionné se trouve de 1579 à 1558 cm^{-1}, dans le cas des composés synthétisés par nous, comme on peut voir dans la figure 1, est superposée aux bandes d'absorption caractéristiques des noyaux benzéniques de 1600 ± ± 25 cm^{-1} et 1580 ± 20 cm^{-1}, qui, à la différence des autres éthers aromatiques,[1,3,4] apparaissent très intenses aux azobiséthers.

PARTIE EXPÉRIMENTALE

Le 4,4'-azodiphénol a été obtenu par réduction en milieu alcalin (KOH) du *p*-nitrophénol.[6]

Le chlorométhylbenzène a été un produit commercial-Riedel. Le 4-méthyl-chlorométhylbenzène a été obtenu par chloration photochimique du *p*-xylène avec du SO_2Cl_2.

Le chlorométhyl-2,4-diméthyl-benzène et le chlorométhyl-2,5-diméthyl-benzène ont été obtenus par chlorométhylation du *m*-xylène, respectivement du *p*-xylène.

Le chlorométhyl-3,5-diméthyl-benzène a été obtenu par chloration photochimique du mésytylène avec du SO_2Cl_2, en utilisant comme initiateur le peroxyde de benzoyle. Cette réaction, ainsi que le produit obtenu ne sont pas décrits dans la littérature.

Le chlorométhyl-2,4,6-triméthyl-benzène a été obtenu par chlorométhylation du mésitylène, en utilisant du formaldéhyde 30%, de l'acide chlorhydrique conc., en tétrachlorure de charbon.

Le 4-chlorométhyl-biphényle a été obtenu par chlorométhylation du biphényle avec du paraformaldéhyde, de l'acide chlorhydrique conc. et du $ZnCl_2$ en acide acétique et éther de pétrole.

Les spectres IR ont été obtenus en pastilles KBr à l'aide d'un appareil Perkin-Elmer 157.

Synthèse du 4,4'-bis(benzyloxy)azobenzène

Dans un ballon à double col de 100 ml (avec rodage de 14,5), muni d'un réfrigérant ascendant et d'un thermomètre, on a introduit 5,35 g (1/40 mole) de 4,4'-azodiphénol, 2 g de NaOH (1/20 mole), 20 ml d'éthanol anhydre et 20 ml de benzène. Le mélange est chauffé à l'ébullition jusqu'à ce que NaOH réagit avec le 4,4'-azodiphénol, en formant un phénoxyde de sodium, partiellement soluble dans le mélange de solvants.

Après environ une heure de chauffage au point d'ébullition, le réfrigérant ascendant est substitué par un réfrigérant pour distillation de 15 ml de mélange azéotrope eau-éthanol-benzène, donc pour l'éloignement de l'eau résultée de la réaction. On ajoute ensuite 6,32 g

---

[5] A. J. Fatiadi, *J. Res. Nat. Bur. Stand.*, A **71**, 277 (1967).
[6] R. Willstätter et M. Benz, *Ber. dtsch. chem. Ges.*, **39**, 3492 (1906).

(1/20 mole) de chlorométhyl-benzène (avec un petit excès), mais le réfrigérant de distillation est changé de nouveau par l'un de reflux, le chauffage étant fait à l'aide d'une lampe à incandescence de 2,5 W à 65—67°. La réaction du chlorométhylbenzène avec le 4,4'-azodiphénoxyde de sodium a lieu, en formant dans le milieu de réaction le chlorure de sodium, qui précipite.

L'azobiséther précipite plus tard, quand la quantité formée est un plus grande, donc la solubilité plus petite, à la température du travail.

Après 5 heures de chauffage, le chauffage est arrêté, mais le ballon où a eu lieu la réaction est laissé refroidir à la température ambiante, pour précipiter une quantité maximale d'azobiséther.

La séparation de l'azobiséther et du chlorure de sodium de la solution qui contient des matières non soumises à la réaction est effectuée par filtration. Une quantité petite d'alcool (2—3 ml) est ajoutée sur le filtre, puis le précipité est lavé à de l'eau et séché dans l'étuve à 105°.

On obtient 7,21 g de 4,4'-bis(benzyloxy)azobenzène. Rendement 73,2 %.

Le rendement dépend de la quantité de solvant dans laquelle a lieu la réaction et du rapport éthanol-benzène.

A une dilution élevée le rendament est petit, parce que une partie d'azobiséther reste en solution, mais la pureté du produit séparé est plus grande.

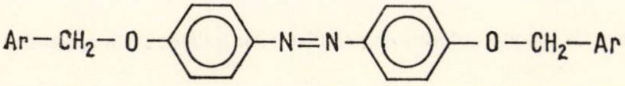
La température de fusion a été déterminée après des recristallisations répétées dans un mélange d'éthanol-benzène (1 : 1 en volume).

Les autres éthers, mentionnés dans le tableau 1, ont été synthétisés de façon identique.

CONCLUSIONS

Le présent article montre que la réaction du 4,4'-azodiphénoxyde de sodium avec les dérivés monochlorométhylés du benzène ou du benzène substitué avec divers substituents a lieu en bonnes conditions, dans un mélange d'éthanol-benzène, à la température d'ébullition du mélange.

On peut obtenir des azobiséthers avec la formule générale :



où Ar représente un aryle, substitué ou non substitué.

MODERN FRIEDEL-CRAFTS CHEMISTRY. II[1]

REARRANGEMENTS ACCOMPANYING BENZENE ALKYLATIONS WITH 1- AND 2-HYDROXY-2-METHYL-1-PHENYLPROPANE, 1- AND 2-CHLORO-2-METHYL-1-PHENYLPROPANE AND 2-METHYL-1-PHENYL-1-PROPENE IN THE PRESENCE OF FRIEDEL-CRAFTS CATALYSTS

ALI ALI KHALAF
Chemistry Department, University of Assiut,
Assiut, Arab Republic of Egypt

Received July 26, 1972

The alkylations of benzene with 1- and 2-hydroxy-2-methyl-1-phenylpropane, with 1- and 2-chloro-2-methyl-1-phenylpropane and with 2-methyl-1-phenyl-1-propene (β,β-dimethylstyrene) in the presence of various Friedel-Crafts catalysts have been investigated. The results of these alkylations were found to be very much similar to those obtained from the alkylations of benzene with neophyl halides and isobutylene dihalides under the same conditions. With the strong catalyst $AlCl_3$, these alkylations gave mixtures consisting of 1,2-diphenyl-2-methylpropane, 1,1-diphenyl-2-methylpropane and DL- and *meso*-2,3-diphenylbutane. With weak catalysts such as $AlCl_3/CH_3NO_2$, $FeCl_3$ or H_2SO_4, the first two isomers were formed only and both of the latter forms were missing from the product mixtures. In all cases, however, the first two isomers were produced in an equilibrium ratio of 2 of the first isomer to 1 of the second. Mechanisms were suggested to account for the results obtained.

In 1952 Somerville and Spoerri [2] reported that the aluminum chloride-catalyzed alkylation of benzene with both 1-hydroxy-2-methyl-2-phenylpropane (neophyl alcohol) and the corresponding 1-chloro-2-methyl-2-phenylpropane (neophyl chloride) gave 1,2-diphenyl-2-methylpropane mixed with varying amounts of the rearrangement product 2,3-diphenylbutane. Similar results were also reported by these [2] and other workers from the $AlCl_3$-catalyzed alkylations of benzene with isobutylene dihalides [3,4,5,6] (1,2-dihalo-2-methylpropanes) which were shown [6] to proceed through the intermediate formation of neophyl halides.

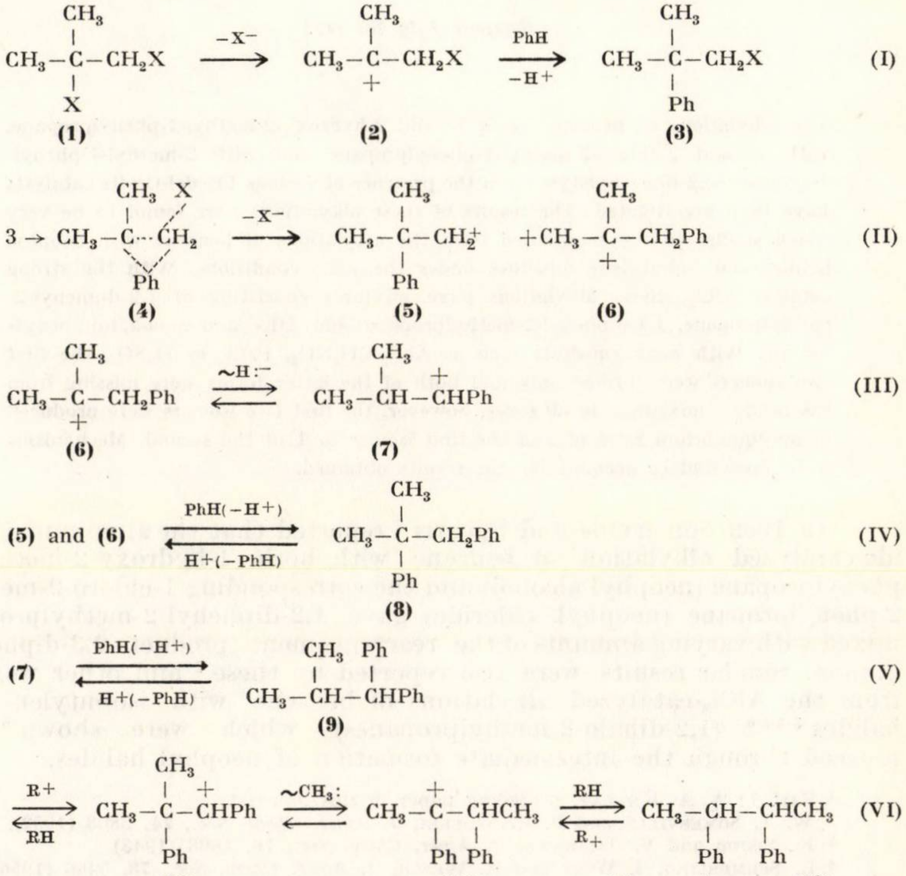
In 1966, the alkylation of benzene with both neophyl chloride and isobutylene dibromide was reinvestigated by Khalaf and Roberts[7] who, with the help of modern instrumental methods of analysis, have discovered that the products from these reactions are more complex than previously described. According to these workers, the products obtained from both halides were mixtures consisting of 1,2-diphenyl-2-methylpropane, 1,1-diphenyl-2-methylpropane and DL- and *meso*-2,3-diphenylbutane in alkylations catalyzed by $AlCl_3$ and of the first two isomers only in aklylations catalyzed by $AlCl_3/CH_3NO_2$ or $FeCl_3$. In all cases, however, the first two isomers were consistantly produced in an equilibrium ratio of about 2 : 1, respectively. To account for the products obtained in the alkylations of benzene with isobutylene dibromide ((**1**), X=Cl) and neophyl chloride (**3**), X=Br) in the presence of Friedel-Crafts catalysts, Khalaf and Roberts[7] suggested the carbonium ion mechanism outlined in equations I–VI of Scheme I:



Scheme I

---

[7] A. A. Khalaf and R. M. Roberts, *J. Org. Chem.*, **31**, 926 (1966).

The production of an equilibrium mixture of (**8**) and (**9**) from the reaction of benzene with either neophyl chloride or isobutylene dibromide, even when the weak catalysts were used, was attributed by the authors to a rapid equilibration of the tertiary carbonium ion 6 (which is produced as an intermediate in both cases) with the secondary benzylic ion (**7**) by a 1,2-hydride shift (equation III) prior to the second alkylation that leads to the formation of (**8**) and (**9**) (equations IV and V).

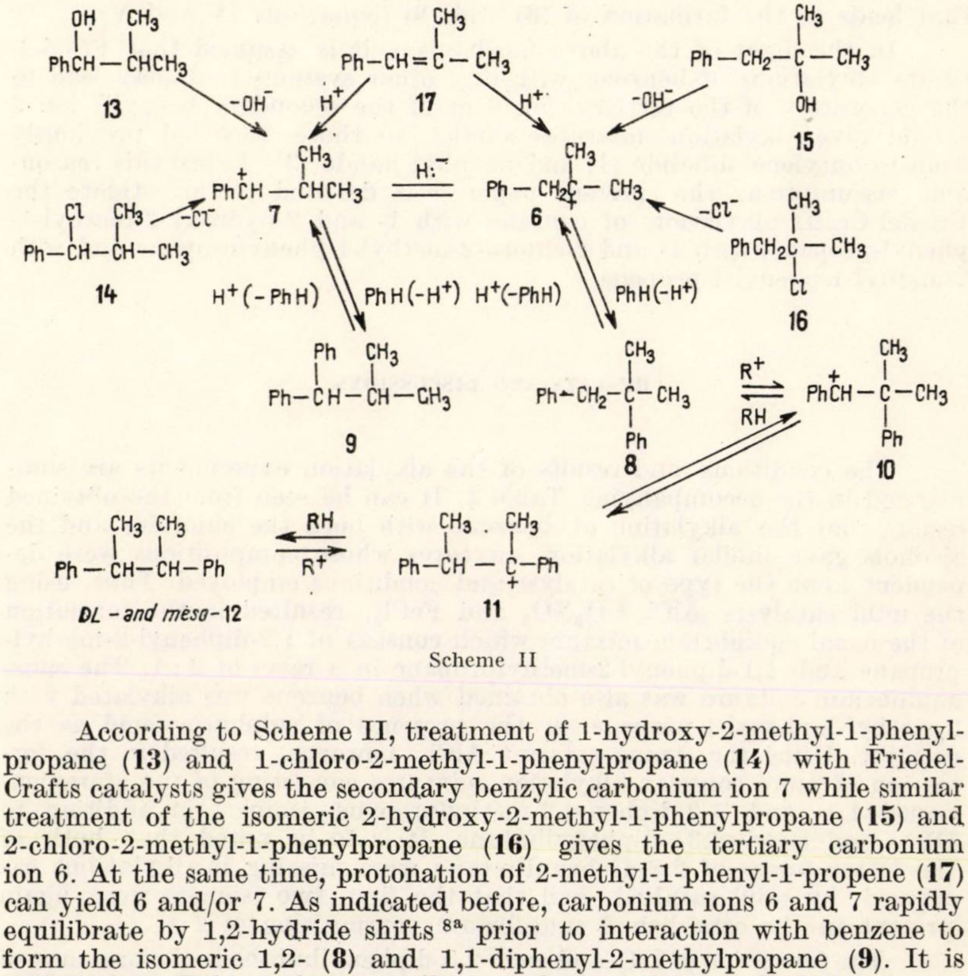
In the light of the above mechanism, it is assumed that Friedel-Crafts alkylations of benzene with any other systems that may lead to the generation of the tertiary ion 6 or of the secondary benzylic ion 7 should give alkylation mixtures similar to those reported previously from isobutylene dihalide (**1**) and neophyl halide (**3**). To test this reasonable assumption, the present paper was devoted to investigate the Friedel-Crafts alkylation of benzene with 1- and 2-hydroxy-2-methyl-1-phenyl-propane, with 1- and 2-chloro-2-methyl-1-phenylpropane and with 2-methyl-1-phenyl-1-propene.

RESULTS AND DISCUSSIONS

The conditions and results of the alkylation experiments are summarized in the accompanying Table 1. It can be seen from the obtained results that the alkylation of benzene with both the chlorides and the alcohols gave similar alkylation mixtures whose compositions were dependent upon the type of catalyst and conditions employed. Thus, using the mild catalysts $AlCl_3/CH_3NO_2$ and $FeCl_3$, resulted in the formation of the usual equilibrium mixture which consists of 1,2-diphenyl-2-methylpropane and 1,1-diphenyl-2-methylpropane in a ratio of 2 : 1. The same equilibrium mitxure was also obtained when benzene was alkylated with 2-methyl-1-phenyl-1-propene in the presence of sulphuric acid as the catalyst. Using the strong catalyst $AlCl_3$, however, resulted in the formation of more complex alkylation mixtures consisting of the aforementioned 1,1- and 1,2-diphenyl-2-methylpropane isomers in addition to DL — and *meso*—2,3—diphenylbutane. It is to be noted that both of the latter forms of 2,3-diphenylbutane were missing in alkylations catalyzed by mild catalysts and that the first two isomers were again present in the established equilibrium composition of 2 :1.

The formation of DL- and *meso*-2,3-diphenylbutane in the presence of the strong catalyst $AlCl_3$ and not in the presence of the weak $AlCl_3/CH_3NO_2$ and $FeCl_3$ catalysts can reasonably be explained in terms of the known ability of $AlCl_3$ to abstract hydride ions. [7] Thus, in the presence of this hydride abstracting catalyst, one can visualize the formation of both forms of 2,3-diphenylbutane occurring through the route (**8**) → (**10**) → → (**11**) → (**12**) (eq. VI of Scheme I and Scheme II). The latter route was formerly supported by the fact that treatment of a pure sample of 1,2-diphenyl-2-methylpropane with $AlCl_3$ gave a mixture in which DL- and *meso*-2,3-diphenylbutane were present. None of the latter forms were obtained, however, when $AlCl_3/CH_3NO_2$ and $FeCl_3$ catalysts were used.[7]

Mechanistically, the results of Table 1 can plausibly be rationalized in terms of the carbonium ion processes outlined in Scheme II.



Scheme II

According to Scheme II, treatment of 1-hydroxy-2-methyl-1-phenylpropane (**13**) and 1-chloro-2-methyl-1-phenylpropane (**14**) with Friedel-Crafts catalysts gives the secondary benzylic carbonium ion 7 while similar treatment of the isomeric 2-hydroxy-2-methyl-1-phenylpropane (**15**) and 2-chloro-2-methyl-1-phenylpropane (**16**) gives the tertiary carbonium ion 6. At the same time, protonation of 2-methyl-1-phenyl-1-propene (**17**) can yield 6 and/or 7. As indicated before, carbonium ions 6 and 7 rapidly equilibrate by 1,2-hydride shifts[8a] prior to interaction with benzene to form the isomeric 1,2- (**8**) and 1,1-diphenyl-2-methylpropane (**9**). It is evident from Table 1 that regardless of which of the five alkylating agents (**13**), (**14**), (**15**), (**16**) or (**17**) is used as starting material, and of whether $AlCl_3$, $AlCl_3/CH_3NO_2$, $FeCl_3$ or H_2SO_4 is used as catalyst, compounds (**8**) and (**9**) are produced in a ratio corresponding to their equilibrium composition. However, it is only in the presence of $AlCl_3$ which has the power to generate carbonium ion (**10**) that the two forms of 2,3-diphenylbutane are actually formed.

[8a] In contrast, in SbF_5-FSO_3H solvent systems Olah and his collaborators have observed only the secondary benzylic cation, phenylisopropylcarbonium ion 8, as the static stable species, which is generated from 1-hydroxy-2-methyl-1-phenyl-propane (13). This demonstrates that in the strong SbF_5-FSO_3H acid system, the secondary benzylic phenylisopropylcarbonium ion (7) appears to be more stable than the tertiary dimethyl-benzylcarbonium ion (6).

In concluding the present discussion, it is worthwhile to mention that the results of Table 1, which show that at equilibrium, compounds (**8**) and (**9**) are present in a ratio of 2 : 1, augment our previous suggestion [8b] that isomer (**8**) is more thermodynamically stable than isomer (**9**). It is also interesting to know that in alkylating arenes with systems leading to the intermediate formation of ions such as (**5**), (**6**) or (**7**), one should expect carbonium ion rearrangements of the type observed in this work and which result in alkylation mixtures composed of various isomers. In fact, further studies to illustrate this are currently under way.

EXPERIMENTAL

ANALYTICAL PROCEDURES

The infrared spectra (i.r.) were done using either a Pye Unicam Sp 200 G Grating IR Spectrophotometer or a Beckman IR-5A Spectrophotometer. A Varian A-60 spectrometer was used for nuclear magnetic resonance (n.m.r.) analysis . Vapour-phase chromatographic analyses (v.p.c.) were carried out using either a Pye Series 104 chromatograph or a Beckman GC-2A instrument. The columns used were : a) 12-ft, 30% silicone gum rubber SE-30 ; b) 12 ft, 15% Bentone-34, c) 12-ft 20% DEGA, d) 5-ft, 3% PEGA, e) 5-ft, 3% DNP.

A. SYNTHESIS OF STARTING MATERIALS AND FINAL PRODUCTS

Synthesis of Starting Materials

Synthesis of 1-Hydroxy-2-methyl-1-'phenylpropane (**13**). This was prepared by the condensation of phenylmagnesium bromide with isobutyraldehyde. In a typical preparation, phenylmagnesium bromide was prepared as usual from 9.6 g. (0.4 g atom) of magnesium turnings, a small crystal of iodine, 62.8 g. (0.4 mole) of bromobenzene and a total of 250 ml of dry ether. To the resulting Grignard reagent, a solution of 36.0 g isobutyraldehyde in 50 ml dry ether was added under cooling and strring. After additon was completed, the reaction mixture was stirred at room temperature for 3 hr and under reflux for another hour. The reaction mixture was then cooled and decomposed by treating with a saturated solution of ammonium chloride. The organic layer was separated, washed with water and dried over anhydrous sodium sulphate. Distillation of the ether under atmospheric pressure left a residue which upon careful distillation under vacuum gave 36 g (60% yield) of the desired alcohol : b.p. 75—79° (1.1—1.2 mm). Reported [9] b.p. : 75—77° at 1.2 mm.

[8b] R. M. Roberts, A. A. Khalaf and R. N. Greene, *J. Amer. Chem., Soc.*, **86**, 2846 (1964).

[9] M. V. Grignard, *Ann. Phys.*, **24**, 467 (1901).

Synthesis of 2-Hydroxy-2-methyl-1-phenylpropane (**15**). This compound was made by the condensation of acetone with benzylmagnesium chloride. In a typical run, benzylmagnesium chloride was prepared as directed[10] from 14.4 g. (0.60 g-atom) of magnesium, a small crystal of iodine, 75.9 g. (0.60 mole) of benzyl chloride, and a total of 300 ml of dry ether. To the resulting Grignard reagent, a solution of 40.6 g (0.7 mole of pure dry acetone in 100 ml dry ether was added under cooling, at such a rate that gentle refluxing occurred. After addition, the reaction mixture was stirred for three hours at room temperature and for another half an hour at reflux temperature. The reaction mixture was then cooled and decomposed with a saturated ammonium chloride solution. The ether layer was separated, washed three times with water and dried over anhydrous sodium sulphate. The ether was removed and the residue was carefully distilled under vacuum to give 68 g (76% yield) of pure 2-hydroxy-2-methyl-1-phenylpropane : b.p. 77–78° (1.2 mm.). Reported b.p. 112–114 at 12 mm[11,12] and 127–128° at 14 mm.[13]

Synthesis of 1- (**14**) *and 2-Chloro-2-methyl-1-phenylpropane* (**16**). These two isomers were prepared by treatment of the respective alcohols with thionyl chloride in pyridine.[14] In a typical treatment, 0.12 mole of thionyl chloride was added with cooling and stirring to a solution of 0.1 mole of the alcohol in 0.12 of pyridine. After addition, the mixture was stirred at room temperature for 2 hr and at 40–50° for 1 hr, then decomposed with cold water. The organic layer was extracted with ether, washed first with cold water, secondly with 5% sodium carbonate and finally with cold water, then dried over anhydrous sodium sulphate. The ether was distilled at atmospheric pressure and the residue was carefully distilled under vacuum.

Applied to 1-hydroxy-2-methyl-1-phenylpropane (**13**) the above procedure gave 1-chloro-2-methyl-1-phenylpropane in 60% yield : b.p. 86–89° (14–15 mm). Reported[15] b.p. : 53° (0.6 mm).

Similarly, 2-hydroxy-2-methyl-1-phenylpropane (**15**) gave 2-chloro-2-methyl-1-phenylpropane (**16**) in 65%. Yield : b.p. 53–55° (0.7 mm). Reported[16] b.p. : 86–87° (9–10 mm). The n.m.r. spectrum of the compound showed the aromatic protons (main peak) at 2.86 T (relative area 5), benzylic protons at 7.03 T (relative area 2) and methyl protons at 8.56 T (relative area 6).

Synthesis of 2-Methyl-1-phenyl-1-propene (*β,β-Dimethylstyrene* (**17**). This was prepared by the dehydration of 1-hydroxy-2-methyl-1-phenylpropane by treatment with 15% sulphuric acid following standard procedures.[17,18] The produced 2-methyl-1-phenyl-1-propene (**17**) was distilled under vacuum : b.p. 70–73° (12.0–12.5 mm). Reported[19] b.p. : 70.5–71.5° (12 mm).

B. *Synthesis of Final Products*

Synthesis of 1,2-Diphenyl-2-methylpropane (**8**). The compound was obtained by the coupling of benzylmagnesium chloride with 2-chloro-2-phenylpropane following essentially the procedure of Khalaf and Roberts[7] : b.p. 145–147° (12.8 mm), lit.[7] b.p. 148–150° (11 mm).

Synthesis of 1,1-Diphenyl-2-methylpropane (**9**). The title compound was prepared starting with phenylmagnesium bromide and methyl isobutyrate following the procedure described by Khalaf and Roberts.[7] The intermediate 1,1-diphenyl-2-methyl-1-propanol was directly reduced to the hydrocarbon using hydrogen and palladium on carbon in glacial acetic acid containing little perchloric acid. The product obtained had a boiling point of 123–124° at 6.4 mm; lit[7] b.p. 168–169° at 29 mm.

Synthesis of DL- and meso-2,3-Diphenylbutane (**12**). These two isomers were obtained by Grignard coupling of 1-bromo-1-phenylethane following literature procedures.[2, 20] The DL-isomer, b.p. 159–160° at 32 mm and lit[7] b.p. 111–112° at 1.8 mm was obtained in 14% yield and the *meso*-isomer, m.p. 124–126° and lit.[7] m.p. 126–127°, was obtained in 21% yield.

ALKYLATION PROCEDURES

In all alkylations, the reactions were carried in a two-necked, round-bottomed flask, equipped with a mechanical stirrer, a pressure equalizing dropping funnel and a reflux condenser fitted with a calcium chloride tube. The catalyst and 90% of the required amount of benzene were introduced into the flask and the alkylating agent dissolved in the rest of benzene was added dropwise (over a period of 30 minutes) through the funnel, while the reactants in the flask were stirred and cooled to about 10–15°. After the addition was complete, the reaction mixture was stirred at room temperature for the rest of the time, then decomposed with water and extracted with ether. The ether layer was washed with water, dried over anhydrous sodium carbonate and the ether was distilled at atmospheric pressure.

In reactions catalyzed by mild catalysts, the identities and relative yields of the products were both determined by v.p.c. analysis and comparison of retention times of the constituents with those of authentic samples under identical conditions. In these reactions, the absolute yields of the products were also determined by v.p.c. using 2,2-diphenylbutane[7] as an internal standard.

In reactions catalyzed by $AlCl_3$, the reaction products were first distilled to obtain a forerun of a mixture of *sec*- and isobutylbenzene and secondly the diphenylated fractions were freed from solid *meso*-2,3-diphenylbutane by successive chilling to 0° and filtration. The identities and relative yields of the liquid diphenylated isomers were then determined by v.p.c. analysis and compared with authentic samples as before.

Data concerning reaction conditions, mole ratios of reactants, compositions and yields of products are summarized in Table 1.

ANALOGUES OF CHLORAMPHENICOL. II

SYNTHESIS OF 2-DICHLOROACETAMIDO-1-(4′-CHLORO-3′-NITROPHENYL)PROPANE-1,3-DIOL

V. V. BADIGER and M. Y. M. JAMKHANDI

Department of Chemistry, Karnatak University, Dharwar-3

Received July 7, 1972

3-Nitro-4-chlorophenacyl bromide (I) on treatment with potassium phtalimide yields the corresponding phtalimido derivative (II). Hydroxymethylation of II followed by Meerwein-Ponndorf-Verley reduction yields racemic *threo*-2-phthalimido-1-(3′-nitro-4′-chlorophenyl)-propane-1,3-diol (IV). The basic hydrolysis of IV gives racemic threo-2-amino-1-(3′-nitro-4′-chlorophenyl) propane-1,3-diol (V) which is resolved by crystallization of the d- and l-salts on treatment with ammonia and subsequent condensation with methyl dichloroacetate to give d- and l-*threo*-2-dichloroacetamido-1-(3′-nitro-4′-chlorophenyl)propane-1,3-diol (VI).

The chemical stability and the ready synthesis of chloramphenicol as well as the relative simplicity of its structure make this antibiotic a popular model for studying the effect of variations in structure on biological activity. Although a large number of analogues of chloramphenicol have been prepared and studied in biological system, the specific structural requirements for maximum antibacterial activity have not been fully determined. Comparison of the relative activities of various analogues suggest that the D-*threo*-2-dichloroacetamido-1,3-propanediol is essential to the activity and the optimum biological activity is dependent on the electron-rich substituents in the aromatic ring. [1] While working on the structure-activity relationships of various analogues of chloramphenicol, Bambas *et al.*, suggested that a halogen atom rather than a nitro group in the *para* position might enhance the activity of the molecule.[2]

On the basis of this premise, and as a part our general programme in the continued search for new antibacterial agents, [3] we have prepared another analogue of chloramphenicol containing both nitro group and chlorine atom in the benzene ring.

The synthetic route chosen for the preparation of *d*- and l-*threo*-2-dichloroacetamido-1-(3′-nitro-4′-chlorophenyl)propane-1,3-diol (IV) is based on the method of Caldwell and Scheweiker.[4]

3-Nitro-4-chloroacetophenone served as a starting material for the reaction sequence. Bromination of 3-nitro-4-chloroacetophenone in the α-position afforded 3-nitro-4-chlorophenacyl bromide (I) which on treatment with potassium phthalimide yielded the corresponding phthalimido derivative II. Hydroxymethylation of II was achieved in ethanolic solution using 37—38% aqueous formaldehyde and sodium bicarbonate. The resulting 2-phthalimido-3-hydroxy-1-(3′-nitro-4′-chlorophenyl)-1-propanone (III) was converted to dl-*threo*-2-phthalimido-1-(3′-nitro-4′-chlorophenyl) propane-1,3-diol (IV) using Meerwein-Ponndorf-Verley reduction. The dl-*threo* configuration was assigned on analogy with the work of earlier workers.[5] Compound IV was hydrolysed by warm alcoholic potassium hydroxide to dl-*threo*-2-amino-1-(3′-nitro-4′-chlorophenyl)-propane-1,3-diol (V). The racemic base V was resolved by crystallization of the d- and l-salts of d-camphorsulfonic acid from isopropyl alcohol. The less soluble salt, m.p. 199—200°, $[\alpha]_D^{30} - 3.2°$ (methanol) upon treatment with ammonium hydroxide gave a (—) base, m.p. 88—89°, $[\alpha]_D^{30} - 17.5°$ (ethyl acetate).

The more soluble salt, m.p. 188–189°, $[\alpha]_D^{30} + 24.0°$ (isopropyl alcohol), yielded, on treatment with ammonia, a (+) base, m.p. 165–66°, $[\alpha]_D^{30} + + 25.5°$ (methanol). The resolved (+) and (−) bases were separately condensed with methyl dichloroacetate to give N-dichloroacetyl derivatives, m.p. 196–98°, $[\alpha]_D^{30} + 18.5°$ (ethyl acetate) and m.p. 182–83°, $[\alpha]_D^{30} - 18.18°$ (ethyl acetate) respectively.

EXPERIMENTAL PROCEDURE

3-NITRO-4-CHLOROPHENACYLBROMIDE (I)

3-Nitro-4-chloroacetophenone (0.5 mole) dissolved in glacial acetic acid (300 g) was warmed and treated with bromine (0.5 mole) dropwise. After the addition, the reaction mixture was stirred for half an hour and poured on crushed ice. The solid material was filtered and washed with ice water. It was crystallized from ethanol in colourless needles, m.p. 84°, yield 81%, (lit. [6] m.p. 84°).

PHTHALIMIDO-3-NITRO-4-CHLOROACETOPHENONE (II)

Potassium phthalimide (0.27 mole) was added to a solution of (0.0253 mole) of 3-nitro-4-chlorophenacyl bromide (I) in 20 ml of dimethylformide. The reaction was slightly exothermic. The temperature was rising to 55° in 5 minutes and the temperature dropped slowly to 25°. After the addition of 30 ml of chloroform the mixture was poured into 100 ml of water. The aqueous phase was separated and extracted with 2 × 100 ml portions of chloroform. The combined chloroform extract was washed with 20 ml of 0.2 N sodium hydroxide solution to remove the unreacted phthalimide and then with 20 ml of water. After drying over anhydrous sodium sulfate, the chloroform was removed, the crystalline residue was triturated with 40 ml of ether to give phthalimido-3-nitro-4-chloroacetophenone as yellow powdery needles, m.p. 170–72°, yield, 60%.

Analyses for $C_{16}H_2ClN_2O_5$: *Calc.* C, 49.35 ; H, 2.5 ;
Found : C, 48.86 ; H, 2.7.

3-NITRO-4-CHLORO-β-(HYDROXYMETHYL)-α-PHTALIMIDOACETOPHENONE (III)

A suspension of 2.0 g (0.0057 mole) of the 3-nitro-4-chlorophthalimidoacetophenone in 5 ml of 37–38% aqueous formaldehyde and 20 ml of 95% ethanol containing a small amount if sodium bicarbonate was stirred at room temperature for two hours. The mixture was poured in ice water and the solid was filtered and dried to give 2.2 g of 3-nitro-4-chloro-β-(hydroxymethyl)-α-phthalimidoacetophenone. It was crystallized from ethyl acetate in shining yellow crystals, m.p. 189–90° yield, 3.1 g.

Analyses for $C_{17}H_{11}ClN_2O_5$: *Calc.* : C, 54.47 ; H, 2.9 ;
Found : C, 54.77 ; N, 2.9.

dl-*threo*-2-Phthalimido-1-(3-nitro-4-chlorophenyl)propane-1,3-diol (IV)

3-Nitro-4-chloro-β-(hydroxymethyl)-α-phthalimidoacetophenone (6.4 g) was added to a hot solution of 8.0 g of aluminum isopropoxide in 70 ml of isopropyl alcohol in a 100 ml flask equipped with a Hans condenser. After a few minutes an opaque red-brown solution was formed and removal of acetone was continued for four hours when the acetone test was negative. During the last 15 minutes the distillation was rapid.

[6] H. G Garg, *J. Indian Chem. Soc.*, **38**, 59 (1961).

The thick red brown residue was allowed to cool just below the reflux temperature before 10 ml of water were added. The mixture was refluxed for 15 minutes and filtered. During the refluxing the colour changed to light yellow. The residue was treated twice by refluxing with 25 ml portions of 80% aqueous isopropyl alcohol. The combined extracts were concentrated *in vaccuo*. The residue was refluxed with 25 ml of ethyl acetate until the oily material had dissolved. The ethyl acetate was removed under reduced pressure. The solid obtained was recrystallized from ethylene dichloride in light yellow needles, m.p. 190—91°, yield, 3.0 g.

Analyses for $C_{17}H_{13}ClN_2O_5$: *Calc.* : C, 54.18 ; H, 3.4 ;
Found : C, 54.00 ; H, 3.6.

dl-*threo*-2-Amino-1-(3′-nitro-4′-chlorophenyl)propane-1,3-diol (V).

3.0 g dl-*threo*-2-phthalimido-1-(3′-nitro-4′-chlorophenyl) propane-1,3-diol was added by stirring to 7.0 ml of hot alcoholic solution of 87% (0.85 mole) potassium hydroxide and stirring was continued for 30 minutes after addition was complete. The orange solution was diluted with 40 ml of cold water and made slightly acidic with hydrochloric acid. The light yellow crystalline product was filtered off, washed well with cold water and dried. It was recrystallized from glacial acetic acid, m.p. 157—58°, yield 2.5 g.

QUATERNARY BASIC AMMONIUM POLYELECTROLYTES. I

QUATERNIZATION REACTION OF SOME TERTIARY AMINES CONTAINING HYDROXYLIC GROUPS WITH CHLOROMETHYLATED POLYSTYRENE

I. PETRARIU, CORNELIA LUCA, IG. POINESCU and M. DIMA

Institute of Macromolecular Chemistry "P. Poni"
Jassy, Aleea Gr. Ghica Vodă Nr. 41 A

Received June 27, 1971

The amination reaction of the chloromethylated polystyrene with dimethyl-2-hydroxyethylamine, dimethyl-2-hydroxypropylamine and diethyl-2-hydroxyethylamine has been studied and the poly[(*p*-vinylbenzyl)dimethyl-2-hydroxyethyl-ammonium chloride], poly[(*p*-vinylbenzyl)dimethyl-2-hydroxypropylammonium chloride] and poly[(*p*-vinylbenzyl) diethyl-2-hydroxyethylammonium chloride] were obtained. The reaction took place initially in the homogeneous medium and then continued in heterogeneous medium. The polyelectrolytes obtained are completely soluble in water.

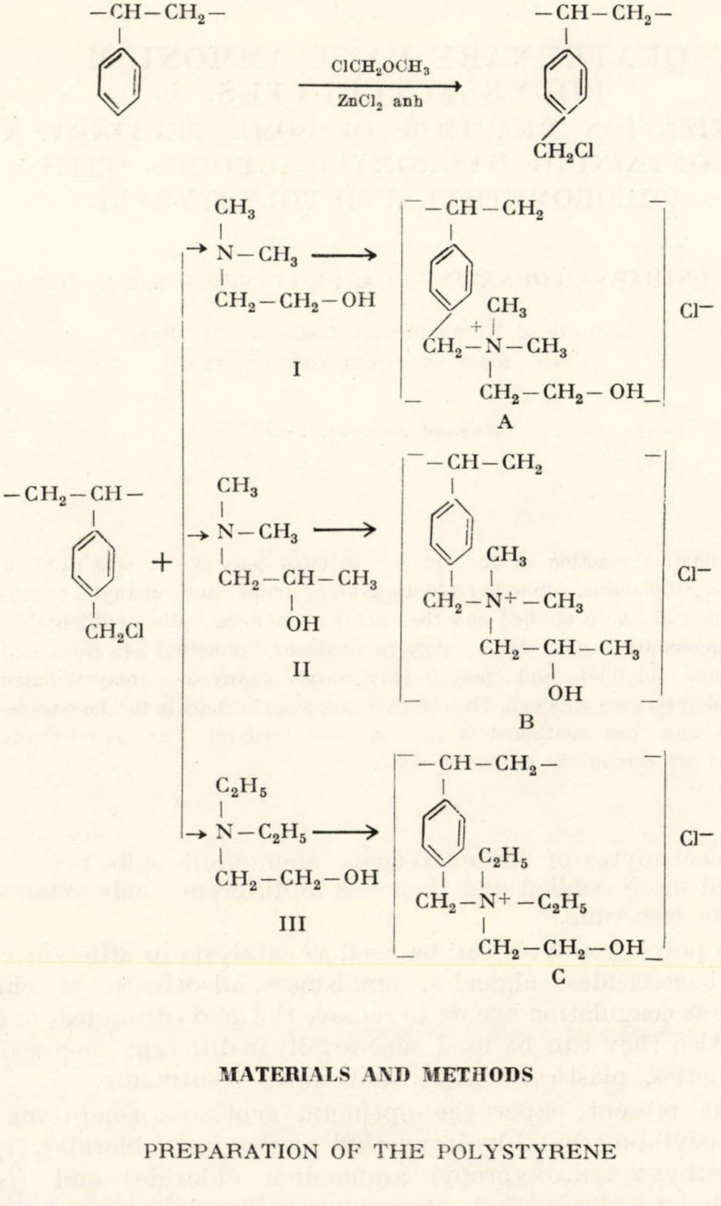
Polyelectrolytes of the quaternary ammonium salts type began to be more and more studied and their use in different fields extended very much in the last time.

These polyelectrolytes can be used as catalysts in different chemical reactions, bactericides, algicides, emulsifiers, adsorbants in chromatography and as coagulation agents to remove the acid substances of aqueous solutions. Also they can be used successfully in different chemical processings, cosmetics, plastics, textiles and water treatments.

In the present paper the optimum synthesis conditions of the [(*p*-vinylbenzyl)dimethyl-2-hydroxyethyl ammonium chloride], [(*p*-vinylbenzyl)dimethyl-2-hydroxypropyl ammonium chloride] and [(*p*-vinylbenzyl)diethyl-2-hydroxyethyl ammonium chloride] type polyelectrolytes as well as their thermal stability and behaviour in solution were studied.

The syntheses have been achieved through the chloromethylation of the polystyrene and amination of the chloromethylated polystyrene with some tertiary amines containing hydroxylic groups.

The general reactions are :



ClCH₂OCH₃
ZnCl₂ anh
–CH–CH₂–
CH₂Cl
CH₃
N–CH₃
CH₂–CH₂–OH
I
CH₂–N⁺–CH₃
CH₂–CH₂–OH
Cl⁻
A
CH₂–CH–CH₃
OH

B
C₂H₅
N–C₂H₅
III
CH₂–N⁺–C₂H₅
C

MATERIALS AND METHODS

PREPARATION OF THE POLYSTYRENE

Polystyrene has been prepared by suspension polymerization and purified by twice precipitating a dioxan solution in methanol[1]. The molecular weight of the purified polystyrene as determined by the viscosimetrie method (Ubbelohde with suspension level) was 17,160.

---

[1] I. Petrariu and J. Stamberg, *Coll. Czech. Chem. Comm.*, **32**, 798 (1967).

The monochlormethylether was prepared according to the method described by Pepper and Paisley.[2] The fraction with b.p. 58–60°, $n^{25} = 1.3949$, obtained by redistillation of the resulting product, has been used.

Obtaining of chloromethylated polystyrene [ClPS]. Polystyrene synthetized as above was chloromethylated according to literature procedure data,[3] to a content of 23.23% Cl, which corresponded to a molar conversion of 100%, monosubstitution of the aromatic nuclei being assumed.

Amination of the chloromethylated polystyrene. The amination reaction of the chloromethylated polystyrene with dimethyl-2-hydroxyethylamine (DMEA), dimethyl-2-hydroxypropylamine (DMPA) and diethyl-2-hydroxyethylamine (DEEA) was carried out in a three-neck flask, fitted with a mercury seal stirrer, a reflux condenser closed with an anhydrous calcium chloride tube, and a thermometer, at 40°, in anhydrous benzene.

The chloromethylated polystyrene and amines were taken in a molar ratio varying between 1 : 1 and 1 : 15 and reaction times of 1–48 hours.

After amination, the polyelectrolyte was filtered, washed with anhydrous benzene to eliminate the excess amine and dried in vacuum. Then, the resulting polyelectrolyte was purified by solving in anhydrous methanol and precipitated with vigorous stirring in anhydrous ethyl ether. The precipitated product was washed with anhydrous ethyl ether and dried to a constant weight in a vacuum oven at 40°. The conversion degree of the quaternary ammonium compounds was determined from the nitrogen content of the resulted compound.

Dimethyl 2 hydroxyethyl amine has been prepared according to Handard's and Inglod's indication.[4]

Diethyl 2 hydroxyethyl amine and dimethyl 2 hydroxypropyl amine (Lab. BDH reagent) were redistilled before use.

The solvent utilized was the anhydrous benzene on metallic sodium.

Ultraviolet spectra were measured on a Unicam SP 800 spectrophotometer using 1 cm quartz cuvettes.

The derivatograms were obtained on a F. Paulik, J. Paulik and L. Erdey derivatograph, in air with a heating regime of 12°/min.

Viscosimetric measurements were made at 25° in an Ubbelohde suspended level type viscosimeter.

RESULTS AND DISCUSSIONS

In order to find the optimum amination conditions of chloromethylated polystyrene with the above mentioned amines, we decided to observe the influence of different factors (the molar ratio, the amination reaction time etc.) on the transformation degree α.

The optimum conversion temperature was found to be 40° in order to avoid the chemical degradation of quaternary ammonium polyelectrolytes.

Amination with an excess of tertiary amine can result in a total or partial replacement of chlorine atoms in the chloromethylated polystyrene. Figure 1 shows that at a 1 : 2 molar ratio ClPS : amines of type I, II, III and reaction temperature of 40° in anhydrous benzene dimethyl-2-hydroxyethylamine proves to be the most reactive, respective the polyelectrolyte *A* reaching in 8 hours a transformation degree of 91.2% while the polyelectrolyte *B* attains 75.73% and the polyelectrolyte *C* only 9.09% conversion.

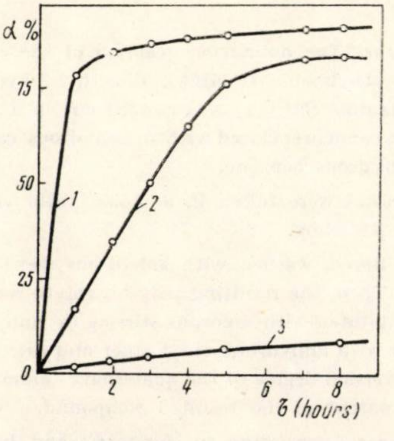

Fig. 1. — Influence of the amination duration (in hours) on the conversion degree α. Reaction conditions: ClPS/amines molar ratio 1/2, 40°, reaction medium=anhydrous benzene ; α=molar conversion degree.

1, polyelectrolyte *A* ; 2, polyelectrolyte *B* ; 3, polyelectrolyte *C*.

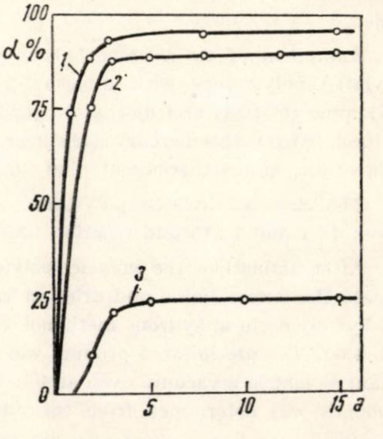

Fig. 2. — Influence of conversion degree α versus ClPS/amines molar ratio in anhydrous benzene ; α = molar conversion degree. *a* = amine moles for 1 mole of chloromethylated polystyrene. Reaction conditions : 40° ; 5 hours.

1, polyelectrolyte *A* ; 2, polyelectrolyte *B* ; 3, polyelectrolyte *C*.

Attempts to enhance the degree of transformation more than 9.09% for polyelectrolyte *C* by increasing the time of the amination reaction have not yielded the desired results. After 48 hours, the degree of transformation was only 14.7%.

In order to increase much more the amination degree of polyelectrolyte *C* as the other polyelectrolytes, the amination process was carried out at higher molar ratios, namely ClPS : amines varying between 1 : 1 and 1 : 15, reaction time 5 hours and temperature 40°. As one can observe from figure 2, the amination degree is 94.0% for the polyelectrolyte *A*, 89% for the polyelectrolyte *B* and 24% for the polyelectrolyte *C*.

A clear image of the maximum amination conditions of these three polyelectrolyte types, is shown in table 1.

The impossibility of a completely amination of the ClPS in the case of amine III, in the above described reaction conditions, may be due to steric factors hindering the interaction of the amination agent with

Table 1

Variation of the maximum conversion degree of chloromethylated polystyrene with the kind of amine; molar ratio ClPS/amine = 1/3, temperature 40°C, reaction medium: anhydrous benzene

Amine	Reaction time hours	Maximum conversion %
Dimethyl-2-hydroxyethylamine	5	94
Dimethyl-2-hydroxypropylamine	5	89
Dicthyl-2-hydroxyethylamine	48	52

each elementary link of the chloromethylated polystyrene as the molecular volume of the amine III is much larger than of the other two amines used in the amination reaction.

A series of viscosimetric measurements of aqueous solutions of the polyelectrolytes *A*, *B*, *C* were carried out (fig. 3).

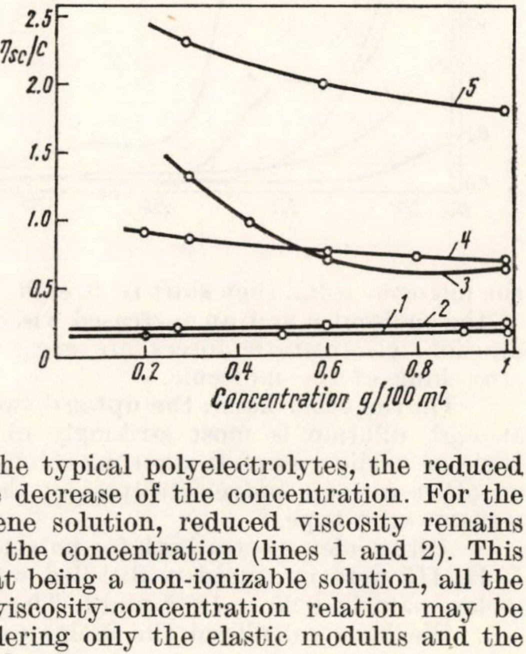

Fig. 3. — Reduced viscosity of unquaternized polymer in anhydrous benzene solution and quaternary ammonium polyelectrolytes of *A*, *B* and *C*-types in aqueous solution.

1, chloromethylated polystyrene; *2*, linear polystyrene; *3*, polyelectrolyte of type *A*; *4*, polyelectrolyte of type *C*; *5*, polyelectrolyte of type *B*.

It is well known that for the typical polyelectrolytes, the reduced viscosity η_{sc}/C increases with the decrease of the concentration. For the unquaternized polymers in benzene solution, reduced viscosity remains unchanged with the variation of the concentration (lines 1 and 2). This may be explained by the fact that being a non-ionizable solution, all the macromolecules are coiled and viscosity-concentration relation may be theoretically calculated by considering only the elastic modulus and the relaxation time of the coiled molecules.

The increase of η_{sc}/C with decreasing concentration is much more visible in the case of *A* and *B* polyelectrolytes, because these have a higher conversion degree (94% and 89%, respectively) than *C* polyelectrolyte whose conversion degree is 52% only. An explanation of this viscosity behaviour can be given. In the flowing liquid the molecules lie athwart to the shear lines and these influence the viscosity by their length number and resistance to elongation. To a large extent, at high concentration, the polyelectrolyte molecules are close together and the reduced viscosity η_{sc}/C represents normal values.

On dilution, the molecules of quaternized polymers which have ionizable groups, begin to space out and, due to the positive charge of the nitrogen atom, they start to stretch. This causes an increased extension of the molecules and an increased viscosity. For a still higher degree of dilution, electrostatic forces are great enough to produce a maximum stretching of the molecule.

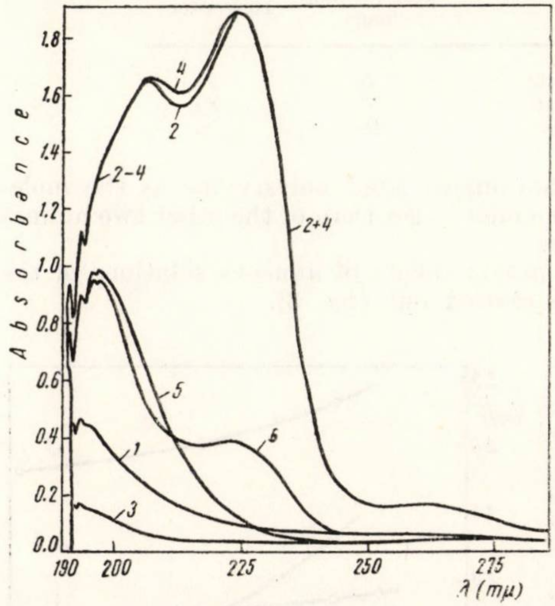

Fig. 4. – U.V. spectra of I, II and III amines and of *A*, *B*, *C* polyelectrolytes.

1, amine I; 2, polyelectrolyte *A*; 3, amine II; 4, polyelectrolyte *B*; 5, amine III; 6, polyelectrolyte *C*.

On the other hand, the upward sweep of the reduced viscosity curve at high dilution is most strikingly observed with polymers containing basic ar acidic groups in aqueous solutions. This finding was also proved on other cationic polyelectrolytes of the polyvinyl – chloroacetate quanternary salts type.[5]

Ultraviolet spectra both for polyelectrolytes *A*, *B*, *C* and the amines I, II, III were measured in distilled water, at a concentration of 1/4000 molar, namely 0.25×10^{-3} mol/l. The results are shown in fig. 4.

We have calculated the molar extinctions ε for the characteristic peaks of the polyelectrolytes *A*, *B* and *C* ($\varepsilon = D/lc$, $D = \log I_0/I$ is the optical density, c = concentration in moles per liter and l = width of the solution layer).

Curves 1, 3 and 5 represent ultraviolet absorption spectra for I, II and III amines. The amines show characteristic peaks at 192, 194 and 196 mμ. These peaks are partially due to the water absorption, because in the curve of water absorption, peaks with less intensity appear in this region.

---

[5] J. P. Newport and R. J. Reyholds, *S. C. I. Monograph*, **26**, 131 (1967).

Curves 2, 4 and 6 show absorption spectra of the *A*, *B* and *C* polyelectrolytes. In the 190–200 mμ region one observes the same peaks as in the case of the above mentioned amines with the difference that here new peaks appear at 207 mμ and 225 mμ. There is also a broader peak at 262 mμ but with less intensity. In the case of *C* polyelectrolyte peaks appear at 225 mμ and 262 mμ only. The peak at 225 mμ is characteristic for the quaternary nitrogen. [6] The ultraviolet absorption spectra may be a control of nitrogen quaternization, because the strong absorption due to N^+ appears at wave lengths of 225 mμ where tertiary nitrogen has no absorption.

In the case of *A* and *B* polyelectrolytes the molar extinction coefficients for the peaks at 207, 225 and 262 mμ have the same values, namely : $\varepsilon_{207\mathrm{m}\mu} = 6640$; $\varepsilon_{262\mathrm{m}\mu} = 640$ and $\varepsilon_{\max} = 7480$ at 225 mμ.

As for the *C* polyelectrolyte, the peaks at 225 mμ and 262 mμ have smaller molar extinction coefficients, namely : $\varepsilon_{\max} = 1540$ at 225 mμ and $\varepsilon_{262\mathrm{m}\mu} = 240$. It is to be noted that the values of molar extinction coefficients for $\chi = 225$ mμ which are characteristic for N^+ agree with the molar transformation degree α.

With respect to the thermal behaviour, differences have been found between polystyrene and the other chemical modified compounds as chloromethylated polystyrene and the three polyelectrolytes *A*, *B* and *C*. These differences consist both in a changed degradation mechanism, illustrated by the decomposition of the unique process of polystyrene and a modification of thermal stability, both conclusions being supported by the data presented in figure 5 and table 2.

The size of this modification can be quantitatively appreciated from the weight loss curves (fig. 5).

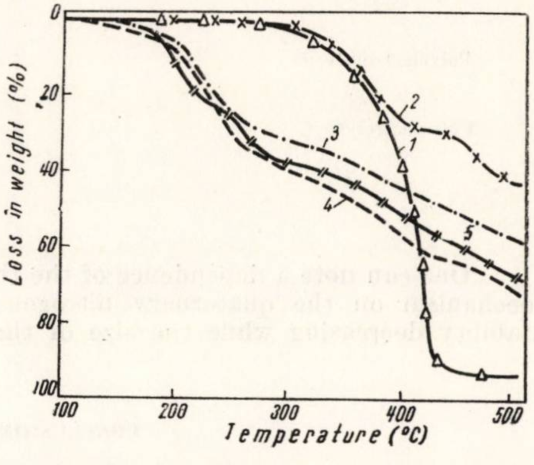

Fig. 5. — Thermogravimetric curves of polystyrene, of chloromethylated polystyrene and those of *A*, *B* and *C* polyelectrolytes.

1, polystyrene ; *2*, chloromethylated polystyrene ; *3*, polyelectrolyte *A* ; *4*, polyelectrolyte *B* ; *5*, polyelectrolyte *C*.

From fig. 5 one can note that polystyrene (curve 1) has a great thermal stability up to 350°, then a sharp weight loss takes place between 350–450°. By chloromethylation (curve 2), thermal stability does not change too much in the 100—400° interval, but the weight losses over this temperature are smaller then in the case of polystyrene. By the quaternization of chloromethylated polystyrene one obtains the three polyelectrolytes *A*, *B* and *C*. The polyelectrolytes show at lower temperature 100—350° a less thermal stability than the polystyrene and chloromethylated polystyrene, but at a higher temperature, at about 500°, the weight losses of the polyelectrolytes are smaller than those of the initial polymer (polystyrene). The conclusions concerning the thermal stability are referring to the initial product of decomposition. At higher temperatures, the stability of the products resulted in the first stage of decomposition is different.

---

[6] B. D. Coleman and R. M. Fuoss, *J. Amer. Chem. Soc.*, **77**, 5472 (1955).

This can be due to their dissimilar structure, because subsequent degradation processes (not to be met with at polystyrene) take place at different intervals of temperature and with variable losses of weight, as we can observe from table 2.

Table 2

DTG analyses data of linear polystyrene and its chemical transformation products (rate of heating 12°/min, max temp 900°C)

Product	Number of degradation processes	Field of temp °C	Loss of weight %
Polystyrene	1	260—450	91
Chloromethylated polystyrene	3	245—420	28.75
		420—510	14.75
		510—900	—
Polyelectrolyte *A*	3	145—310	31.30
		310—440	17.00
		440—600	31.40
Polyelectrolyte *B*	3	150—310	38.50
		330—450	22.60
		450—900	—
Polyelectrolyte *C*	4	150—220	16.66
		220—320	20.77
		320—430	17.20
		450—605	35.00

One can note a dependence of the thermal stability and degradation mechanism on the quaternary nitrogen substituents size, the thermal stability decreasing while the size of the substituents increases.

CONCLUSIONS

The amination reaction of the chloromethylated polystyrene with dimethyl-2-hydroxyethylamine, dimethyl-2-hydroxypropylamine and diethyl-2-hydroxyethylamine has been studied. The polyelectrolyte thus obtained were characterized from the point of view of their thermal stability and their behaviour in aqueous solution.

Revue Roumaine de Chimie, **18**, *3*, 501 – 506 (1973)

METHODS FOR THE DETERMINATION OF TOLAZOLINE VISIBLE AND INFRARED SPECTRA OF THE COMBINATION WITH AMMONIUM REINECKATE

GRIGORE TEODORESCU

Polytechnic Institute of Bucharest
Department of Inorganic and Analytical Chemistry
Str. Polizu, 1, Bucharest, Romania

Received August 12, 1972

The present paper presents methods of determining the tolazoline based upon its combination with ammonium reineckate, the dissolving of the obtained compound in acetone followed by the precipitation of the reineckate anion as silver reineckate and the titration of the silver nitrate excess with ammonium thiocyanate. Since the obtained compound is soluble in acetone, forming a coloured solution, the tolazoline has been determined colorimatrically as well. The structure of the obtained compound has been assigned by the determination of the molecular mass, by means of visible spectra for ammonium reineckate and tolazoline reineckate. In order to determine the structure of tolazoline reineckate, infrared spectrum of tolazoline and of its compound, obtained by combination with ammonium reineckate has also been recorded.

The tolazoline (benzazoline, periphen), 2-benzyl-4,5-dihydroimidazole hydrochloride abr. CBI, is a blood-vessel dilator able to generate a rise of the blood flow, being used for troubles of peripheric vessels.

The known analytical determination of tolazoline is based upon the titration of the chloride anion. The method can be precise only with a chemically pure product (free of HCl or NaCl). In order to determine a less pure substance (as it may appear in the process of its manufacture), we considered necessary to improve the method of determination of the pure substance, a method based upon the reaction of tolazoline with ammonium reineckate, $NH_4[Cr(NCS)_4(NH_3)_2]$, abr. $(Rc^-NH_4^+)$, a reagent that we also used for the determination of other substances.[1-10]

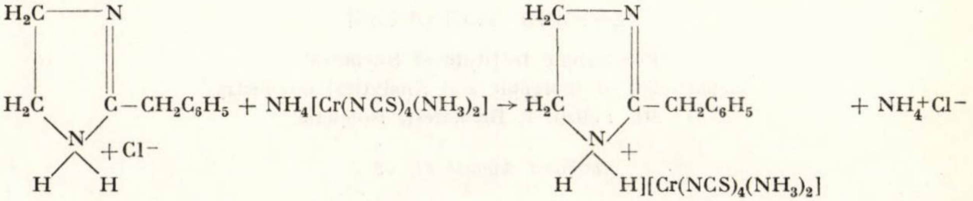
METHOD

The reaction takes place even in a neutral aqueous solution, as tolazoline hydrochloride contains a quaternary nitrogen atom.

Tolazoline is precipitated with a mole $Rc^-NH_4^+$ according to the equation :



The obtained combination is insoluble in water and soluble in acetone.

The reaction with $Rc^-NH_4^+$ was also used in the determination of tolazoline by volumetric, colorimetric and spectral methods.

1. VOLUMETRIC METHOD

The aqueous solution of tolazoline is precipitated with 2% $Rc^-NH_4^+$ according to the above mentioned equation.

The resulting violet-pink precipitate is filtered, washed with water and dissolved in acetone.

The acetone solution is treated with silver nitrate solution in excess. Silver reineckate precipitates according to the equation :

$$[Cr(NCS)_4(NH_3)_2]^- + Ag^+ \rightarrow Ag[Cr(NCS)_4(NH_3)_2]$$

After filtering and washing of the product, the excess of silver nitrate is titrated with thiocyanate in the presence of iron (III) ammonium alum as an indicator.

1.1. *Experimental part*

25 ml Solution containing 0.01 g substance (CB I) per 1 vol (0.25 g in all) are quantitatively brought in a standard flask of 250 ml with distilled water.

Samples of 10−24 ml are taken out of this solution and precipitated with an approximately equal volume of freshly prepared 2 % $Rc^-NH_4^+$ solution, by gradually adding and continuously stirring, until the solution above the precipitate becomes dark violet-red. The obtained product is filtered on a G_3 filtrable crucible, carried along by means of 0.1 % $Rc^-NH_4^+$ solution and with cold (4° C) distilled water until the solution becomes colourless, and in the end washed two times with 5−10 ml ether.

The compound is directly dissolved in 10−20 ml acetone on a filtrable crucible which is then washed with 20−30 ml distilled water, the whole solution being collected in a 250 ml flask. 100 ml distilled water, 15 ml silver nitrate 0.1 N and 2 drops of nitric acid

2 N are added. The silver reineckate is precipitated. The precipitate is filtered, then washed with distilled water by decanting and the filtrate is collected together with the washing water in a 750 ml titrating decanter. In the same decanter, 2 ml saturated solution of iron (III), ammonium alum (about 40 %) and 3–4 drops of nitric acid 2 N are added, and the excess of silver nitrate is titrated by means of ammonium thiocyanate 0.1 of factor = 1.0638.

To 1 ml silver nitrate 0.1 N corresponds 0.01965 g tolazoline. The results are given in Table 1.

Table 1

Determination of CBI by volumetric method

2. COLORIMETRIC METHOD

2.1. *Method*

CBI is precipitated with $Rc^-NH_4^+$, in the same way as by the volumetric method, in molar ratio 1 : 1. Since the product is soluble in acetone forming a red-coloured solution, CBI can be easily determined colorimetrically as well.

2.2. *Procedure*

The analysis is carried out by the method of standard curves. A $Rc^-NH_4^+$ solution of $T = 0.0140$ g/ml was used, from which corresponding volumes were taken into 100 ml standard flasks, diluted in 50 ml acetone and filled up to the mark with distilled water, so that solutions of concentrations $T = 0.000147$; 0.000294 ; 0.000441 ; 0.000588 were obtained.

A Lange photocolorimeter was used, with green filters ($\lambda = 533$ nm) and the standard curve was determined.

Samples containing 0.0140–0.0240 g/ml were taken out of the CBI solution of $T = 0.0010$ g/ml and precipitated with $Rc^-NH_4^+$ as in the volumetrical method. After filtering and washing, the samples were quantitatively dissolved in acetone, the solutions being col-

lected in 100 ml standard flasks which were then filled up to the mark with distilled water. After homogenization they were measured colorimetrically (Table 2).

3. SPECTRAL STUDY

3.1. *Characterization of visible spectrum of tolazoline reineckate*

The structure of the substance obtained from CBI and $Rc^{-}NH_4^{+}$ through the above mentioned method can be assigned by determining its molecular mass by means of the absorbance (A) and of the absorptivity (K) of visible spectra.

A common feature of the visible spectra for $Rc^{-}NH_4^{+}$ and for CBI reineckate is that the absorption maxima (λ_{max}) are nearly the same, namely $\lambda_{max} = 520-525$ nm (diagram 1) for $Rc^{-}NH_4^{+}$ (in ethanol 95%) and $\lambda_{max} = 525$ nm (diagram 2) for CBI reineckate (in ethanol 95% as well).

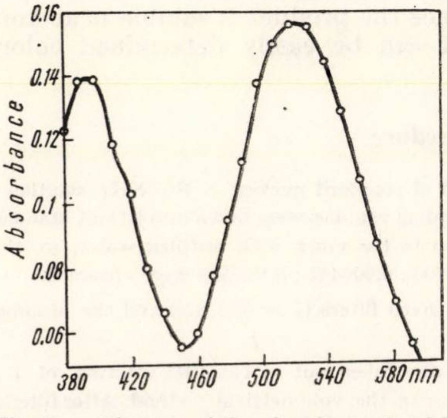

Fig. 1. — Diagram of the absorbancy in visible for ammonium reineckate $g_1 = 0.1\%$; $1 = 0.5$ cm; solvent = 95% ethanol.

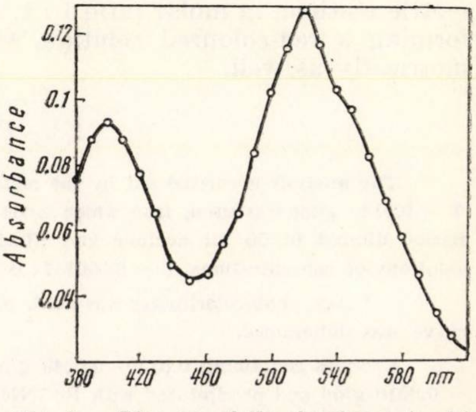

Fig. 2. — Diagram of the absorbancy in visible for tolazoline reineckate $g_1 = 0.1$; $1 = 0.5$ cm; solvent = 95% ethanol.

The absorptivity was determined (K) according to the following relation, with $R_c^-NH_4^+$ in ethanol 95% at a concentration $c = 0.00297$ mole $R^-NH_4^+$, in a 0.5 cm long absorption cell and for an absorbance (A) read on diagram 1 and corresponding to the value $\lambda_{max} = 520-525$ nm. Since the determination was made with $l = 0.5$ cm, value A will be doubled for $l = 1$ cm.

$$K_{(ethanol)} = 2 \times 0.154/0.00297 = 103.7$$

Value K, determined for $Rc^-NH_4^+$, can be considered, within limits of admissible errors, as being also available for CBI reineckate, as λ_{max} for CBI reineckate is equal (or nearly so) to λ_{max} for $Rc^-NH_4^+$ (diagrams 1 and 2).

In order to determine the molecular mass (M_d) the following relation will be used:

$$M_d = g_1/100 \times K/A\,.1.1000 \tag{1}$$

In case $g_1 = 0.1$ g CBI reineckate per 100 ml solution and $l = 1$ cm, relation (1) becomes:

$$M_d = K/A. \tag{2}$$

Practically, the determination of visible absorption of CBI reineckate in 95% ethanol is carried out. The absorbance for $\lambda_{max} = 520-530$ nm at a concentration of 0.1% and in a cell of $l = 0.5$ cm, under given conditions, is 0.108. For $l = 1$ cm, value A is doubled. Replacing K in relation (2) by the determined value for $Rc^-NH_4^+$, the molecular mass is obtained:

$$M_d = \frac{103.7}{2 \times 0.108} = 480. \tag{3}$$

If this value is compared with that of the calculated molecular mass ($M_c = 479.4$), they are seen to be very close, which proves the monoreineckate structure.

A spectrophotometer Zeiss VSU-1 with tubs, whose length was of 0.5 cm and 1 cm, was used.

3.2. *Characterization of tolazoline reineckate in infrared*

The infrared spectrum of CBI reineckate has also been recorded for the structural characterization of the compound.

The IR spectrum of CBI reineckate has been interpreted by comparing it with the $Rc^{-}NH_4^{+}$ spectrum (Table 3).

The IR spectrum of the complex presents bands found in the IR spectrum of ammonium reineckate, which can be attributed to the NH_3 and NCS groups in the reineckate anion of the compound (Table 4); they appear at 490 (δ_{NCS}), 1270 $\overset{\text{Sym}}{\underset{\text{N-H}}{\delta\,\mathrm{NH_3}}}$, 2100 ($\nu_{C-N}$), 3170−3310 $\overset{\text{Sym}}{\underset{\text{N-H}}{\nu\,\mathrm{NH_3}}}$

It also shows bands corresponding to the organic base (Table 4). These bands, at 465 cm^{-1}, 525 cm^{-1}, 749 cm^{-1}, 1300 cm^{-1}, 1620 cm^{-1}, 2680 cm^{-1}, 2970 cm^{-1}, appear also in the spectrum of the compound, where they are slightly altered in position and intensity.

POLAROGRAPHIC DETERMINATION OF ANTHRAQUINONE, 2-CHLOROANTHRAQUINONE AND 2-AMINOANTHRAQUINONE

SILVIU-DUMITRU POPESCU

Institute of Chemical Researches
Splaiul Independenței, 202, Bucharest, Romania

Received March 24, 1972

By using dimethylformamide as the most suitable solvent, a solution of ammonium acetate as support of basic electrolyte, and by adding a gelatine solution to suppress the maxima, a new polarographic method for determining anthraquinone, 2-chloroanthraquinone and 2-aminoanthraquinone has been achieved. After removing the oxygen, the organic compound is polarographed, the reduction taking place in a domain of which the potential of deposits corresponds to an appreciable value and is reported to the mercury dropping electrode.

Anthraquinone is an organic compound with wide uses in the dye technology. For this reason, the search for rapid and accurate dosage methods for this substance represents an analytical problem of high practical interest.

Among the analytical methods, polarography gives the most conclusive results. The polarographic method described in the present note offers high advantages compared to the similar methods already reported in the literature. Thus, a polarographic method based on the anthraquinone determination in LiCl or LiOH media [1] implied a lesser precision and is less easy to handle as a working technique, especially due to the presence of LiCl, which is a hygroscopic salt. Other authors [2] have suggested the polarographic determination of anthraquinone by using acetic acid and ammonium acetate as the base electrolyte, which may cause the inconvenience that benzoylbenzoic acid, as an impurity, forms further polarographic steps which could falsify the analytical results.

Finally, when sulphuric acid was used[3] the sensitivity of the polarographic method was noticeably lowered and the sample processing became too intricate.

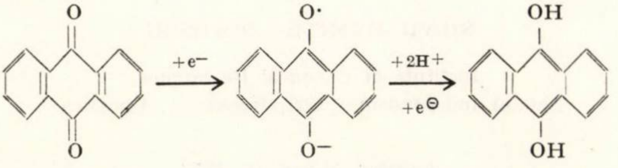
[2] T. Isshiki and K. Tada, *Pharm. Bull.*, **2**, 266 (1954).

[3] J. C. James, *Trans. Faraday Soc.*, **47**, 1240 (1951).

The advantage of the polarographic method, as described below, consists in the possibility of removing all these difficulties which affect the course of the analysis, and in its exactness, rapidity and simplicity, as the experimental tests carried out in laboratory have shown to be fulfilled.

Anthraquinone polarography is based on the anthraquinone reduction up to anthrahydroquinone, according to the following reaction scheme:



Anthraquinone Semiquinone Anthrahydroquinone

The reduction potentials are reproducible and characteristic for the aforementioned derivative, and the existing impurities do not influence the analysis.

EXPERIMENTAL

REAGENTS

1. Pure N,N′-dimethylformamide
2. Ammonium acetate, 5 M solution
3. Solution of gelatine 1 %
4. Standard solutions of anthraquinone and 2-aminoanthraquinone.

A. *Standard solution of anthraquinone*

0.1 g of anthraquinone p.a. are weighed and dissolved in N,N′-dimethylformamide, the solution being transferred into a graduated flask of 100 ml and brought up to the mark with the same organic solvent (1 ml standard solution = 1 mg anthraquinone).

B. *Standard solution of 2-aminoanthraquinone*

0.1 g 2-aminoanthraquinone p.a. is weighed and then introduced into a graduated flask of 100 ml dissolved and brought up to the mark using N,N′-dimethylformamide in the same way as for anthraquinone (1 ml standard solution = 1 mg 2-aminoanthraquinone).

The standard solutions are left to stay in a dark place.

APPARATUS

The measurements were carried out on a LP_{60} polarograph with a Sefram-Graphispot recorder having a maximum sensitivity of 0.25 μA.

An electrolytic condenser of 180 μF was connected to the terminals of the Sefram recorder, this capacity being necessary to remove the current oscillations during the formation and detachment of the mercury drops.

A capillary of 0.07 mm was used as a dropping electrode, the flow rate of mercury being of one drop for each 3 seconds.

PROCEDURE

A sample of 0.1 g is weighed and introduced into a graduated flask of 100 ml, and then dissolved and brought to the graduation mark with dimethylformamide.

After a good homogenization, a 5 ml solution is introduced with a volume pipette into a graduated flask of 25 ml, to which 4 ml of 5 M of ammonium acetate solution as well as 1 ml of gelatine solution 1% is then added.

The content is once more homogenized and slightly cooled and reached to the graduation with dimethylformamide.

The samples are left to stay in a dark place for 5 min, and bubbled with methane or nitrogen (30 min), polarographed at potentials comprised within −0.42 V and −0.56 V, the capillary tube having a flow rate of one drop per three seconds.

The samples were recorded in comparison to a standard obtained under the same experimental conditions.

For 2-aminoanthraquinone the standard used was prepared from the same substance of *p.a.* purity.

The concentration of anthraquinone is given by the formula :

$$\% C = (H_p \cdot C_{et} / H_{et} \cdot G) \cdot 100$$

where :

C = is the concentration of the sample,

H_p = the step height of the sample (in mm),

H_{et} = the step height of the standard (in mm),

C_{et} = the standard concentration in mg/ml,

G = the sample weight expressed in grams.

CONCLUSIONS

1. The method is reproducible and the errors do not exceed ± 1% which is confirmed by the calibration curve of anthraquinone as shown in figure 1.

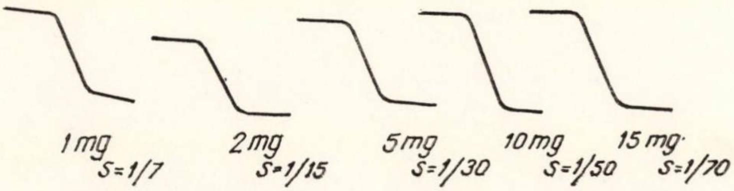


Fig. 1. — Calibration curves of the anthraquinone standard at various concentrations.

2. The curves recorded at different periods of time are quite similar, no changes being observed with their heights.

3. Impurities, such as benzoylbenzoic acid (fig. 2-b), phtalic anhydride (fig. 2-c), phenanthrene (fig. 2-d), anthracene (fig. 2-e), carbazole (fig. 2-f), and maleic anhydride (fig. 2-g) did not influence the polarographic analysis, even at the 1 : 10 anthraquinone/impurity ratio.

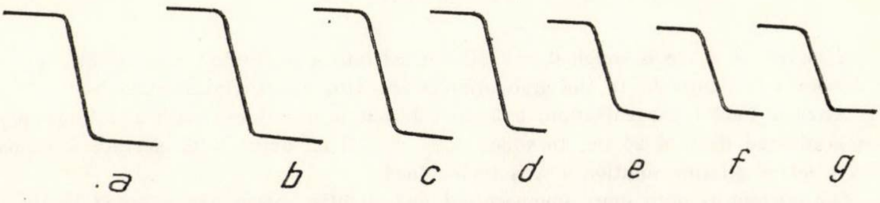

Fig. 2. — Comparative polarograms of anthraquinone for various impurities introduced :

a. – anthraquinone (standard), 5 mg S = 1/20 ; b. – benzoylbenzoic acid, 50 mg S = 1/20 ; c. – phtalic anhydride, 50 mg S = 1/20 ; d. – phenanthrene, 50 mg S = 1/20 ; e. – anthracene, 50 mg S = 1/30 ; f. – carbazole, 50 mg S = 1/30 ; g. – maleic anhydride, 50 mg S = 1/30.

The samples of anthraquinone should be kept in a dark place in order to remove the occurrence of photochemical or oxidation reactions.

MECHANISM OF RADIOLYTIC REDUCTION OF Cr^{VI} IN AQUEOUS SOLUTIONS

MARIA FITI

Institute of Atomic Physics, P. O. Box 35, Bucharest, Romania

Received October 8, 1972

The mechanism of Cr^{VI} reduction to Cr^{III} hydrated electrons and hydrogen atoms is discussed. In the presence of specific OH radical scavengers, such as alcohols, the Cr^{VI} reduction occurs with $G(-Cr^{VI}) = G(Cr^{III})$ depending on Cr^{VI} concentration, acidity, additives and dose-rate. In neutral, deaerated solutions and in the presence of *t*-butanol the reduction occurs directly by e^-_{aq} and H ($G_{red} = G_H + G_{e_{aq}} = 3.2$) because $G - Cr^{VI} \simeq 1/3\, G_{red} = 1.05 \pm 0.05$. In the presence of methanol and in acid solutions $G\,(-Cr^{VI})$ exceeds largely the value required by the above equation; the reduction is controlled by chain reaction mechanism, propagated by the H, HO_2 and $.CH_2OH$ radicals.

INTRODUCTION

The Cr^{VI} as chromate and/or dichromate ions are quite resistant to radiolysis in its pure, neutral, and aerated aqueous solution because the ions reduced by e^-_{aq} and H atoms are oxidized back by OH radicals issuing from water radiolysis.

It is well known that the chromate and dichromate anions are very powerful oxidizing agents. In their aqueous solutions, subjected to ionizing radiation, it is expected that they would react with reducing species, e^-_{aq} and H, present in these conditions.

The overall equation of water radiolysis is

$$H_2O \rightarrow e^-_{aq},\ H,\ OH,\ H_2O_2,\ H_2 \qquad (A)$$

with the G values as follows:

$$G_{e^-_{aq}} = 2.70, \quad G_{OH} = 2.70, \quad G_H = 0.45$$

$$G_{H_2} = 0.55, \quad G_{H_2O_2} = 0.70.$$

The rate constants of chromate and dichromate reactions with e_{aq}^- have been measured by pulse radiolysis method [1,2]:
$k(CrO_4^{2-}) = 1.8 \times 10^{10}$ mol^{-1} s^{-1}, $k(Cr_2O_7^{2-}) = 4.4 \times 10^{10}$ mol^{-1} s^{-1}
A Cr^{V} transient is presumably formed, by the reaction of either e_{aq}^- or H atom and it is reoxidized back by OH radical reaction with an estimated rate constant of 5×10^{10} mol^{-1} s^{-1}. It is also noted [2] that the transient species goes back to the original compound by a second order process.

The apparent stability of Cr^{VI} is due to opposite processes and for this reason there are quite few data on the detailed mechanism of radiolytic reduction of chromate and dichromate anions in aqueous solution.

For practical and theoretical reasons, it is of interest to have more information on the reactions which occur and we are reporting here new relevant data on the reduction mechanism.

EXPERIMENTAL

Materials. Analytical grade Merck potasium chromate and potasium dichromate is used to make up the solutions in triply distilled water. All other materials were of analytical grade purity, without further purification except *t*-butanol which was purified by three recrystallizations.

Irradiations were carried out in 10 ml samples, contained in cylindrical Pyrex vessels, at the 2 MeV electron beam, delivered by a linear accelerator and to the γ-rays produced by stopping the above electron beam through the tungsten windows. The dose-rates available with these facilities were of 1.6×10^{18} eV ml^{-1} s^{-1}, for the electron beam and 4.8×10^{15} eV ml^{-1} s^{-1}, for γ-rays.

Analysis. The Cr^{VI} concentration was followed spectrophotometrically at $\lambda = 374$ nm, the chromate anion absorption peak. The dichromate solutions were analysed as chromate, adding NaOH 4% aqueous solution to irradiated dichromate solution. [3]

Trivalent chromium was identified from its green Cr_2O_3 oxide and by conversion to a violet trioxalate complex, [4], that may be read at $\lambda = 420$ or 560 nm.

The yield of molecular hydrogen was determined by gas chromatography, on a molecular sieve 5 A column, with argon as carrier gas.

The hydrogen was extracted from solutions using a modified Van Slyke extractor.

In solutions containing methanol, we identified carbonyl group of formaldehyde by its specific reaction with 2–4 dinitrophenylhidrazine.

RESULTS AND DISCUSSIONS

A. NEUTRAL SOLUTIONS

As we expected the pure, deaerated solution of CrO_4^{2-} ions of low concentrations, irradiated to electron and γ-rays beam gives a very low yield of $G(-Cr^{VI}) \simeq 0.10$.

---

[4] H. M. Hershensen, "Ultraviolet and Visible Absorption Spectra". Academic Press, New York, 1959, p. 1945.

The reactions which occur are essentially the following:

$$Cr^{VI} + e_{aq}^{-}(H) \rightarrow Cr \tag{1}$$

$$Cr^{V} + OH \rightarrow Cr^{VI}. \tag{2}$$

In order to avoid the reaction (2) we added to the Cr^{VI} solutions powerful and specific OH scavengers, namely alcohols as: methanol, ethanol, *t*-butanol etc., which react with OH and H, but are quite unreactive towards e_{aq}^{-}:

$$CH_3OH + OH \rightarrow .CH_2OH + H_2O \tag{3}$$

$$CH_3OH + H \rightarrow .CH_2OH + H_2 \tag{4}$$

The organic radical produced from these reactions, is usually a strong reducing species leading to the corresponding aldehyde:

$$M^{n+} + .CH_2OH \rightarrow M^{(n-1)+} + H_2C{=}O + H. \tag{5}$$

In the particular case of *t*-butanol, the radical formed by reactions like (3) and (4) is quite unreactive [5] and consequently the only reducing radicals are e_{aq}^{-} and H, issuing from water radiolysis.

In order to study the reduction by these species, we used *t*-butanol as OH scavenger. Its reactivity towards H atom is also very small as it appears from the rate constants [6]:

$$k_H = 1.0 \times 10^5 \text{ mol}^{-1} \text{ s}^{-1}, \quad k_{OH} = 2.8 \times 10^8 \text{ mol}^{-1} \text{ s}^{-1}.$$

The results concerning the Cr^{VI} reduction, in neutral solutions containing *t*-butanol, are given in the table 1.

Table 1

$G(-Cr^{VI})$ in neutral aqueous solution of CrO_4^{2-} in the presence of *t*-butanol

CrO_4^{2-}, N / *t*-butanol, M	2×10^{-4}	5×10^{-4}	10^{-3}	2×10^{-3}	5×10^{-3}	Dose-rate $eV\cdot ml^{-1}\,s^{-1}$
0.1	0.30	0.30	0.30	0.35	0.35	1.6×10^{18}

[5] J. H. BAXENDALE, M. A. I. RODGERS and M. D. WARD, *J. Chem. Soc.*, *A*, **1970**, 1246.
[6] M. ANBAR and P. NETA, Israel Atomic Energy Commission, Report—IA 1079, 1966.

In these conditions the Cr^{VI} reduction is due mainly to e^-_{aq} because $G_{e^-_{aq}} = 2.70$ is much higher than $G_H = 0.55$ and, which is more, H atoms could be also scavenged by *t*-butanol.

We verified the scavenging of primary H atoms by *t*-butanol by measuring the $G(H_2)$ as well. This value is essentially equal to $G_{H_2} = 0.45$, provided by water radiolysis, but for large concentrations of *t*-butanol and small concentrations of chromate ions we observed a small increase of measured yield up to $G(H_2) = 0.70$.

For 2×10^{-4} N, CrO_4^{2-} and 2M *t*-butanol we obtained this maximum value which shows the high reactivity of CrO_4^{2-} ions towards H atoms, compared with that of *t*-butanol.

From the above results it is clear that $G(-Cr^{VI})$ can be explained by the e^-_{aq} and H atom reactions such that:

$$Cr^{VI} + e^-_{aq}(H) \rightarrow Cr^{V} \tag{1}$$

$$Cr^{V} + e^-_{aq}(H) \rightarrow Cr^{IV} \tag{6}$$

$$Cr^{IV} + e^-_{aq}(H) \rightarrow Cr^{III} \tag{7}$$

These reactions lead to the $G(-Cr^{VI})$ value required by stoichiometric relation:

$$G(-Cr^{VI}) = G(Cr^{III}) = 1/3\ G_{red} \tag{B}$$

As we see from table 1, the $G(-Cr^{VI})$, obtained by γ-rays irradiation at quite small dose-rate, satisfies that relation while, in the case of large dose-rate of pulsed electron beam irradiations, $G(-Cr^{VI})$ is roughly three times smaller.

This large dose effect is due to the bimolecular decay of the Cr^{V} transient, fact which also has been shown by pulse radiolysis experiments:[2]

$$2Cr^{V} \rightarrow Cr^{VI} + Cr^{IV} \tag{8}$$

or:

$$Cr^{V} + Cr^{IV} \rightarrow Cr^{VI} + Cr^{III} \tag{9}$$

These reactions obviously supress the reduction, because the Cr^{VI} is partially back reformed.

It must be noticed that $G(-Cr^{VI})$ practically does not depend on Cr^{VI} concentration; the small concentration effect from table 1 is correlated to the corresponding small scavenging effect of H atoms by *t*-butanol.

B. ACID SOLUTIONS

The results concerning the radiolytic reduction of Cr^{VI} ions in acid solutions are quite different from the previous ones, in neutral solutions.

$G(-Cr^{VI})$ is higher in absence of any alcohol and depends strongly on Cr^{VI} concentration, acidity and dose-rate.

The obtained results are plotted in figure 1.

The dose-rate effect is smaller than before; in irradiation the $G(-Cr^{VI})$ is twice higher than in electron beam irradiation. The Cr^{VI} concentration effect is high and also we must notice the effect of acidity which is quite significant (curves 2 and 3).

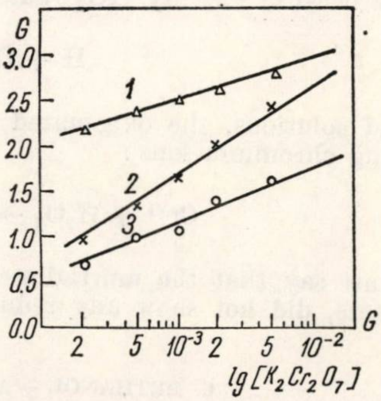

Fig. 1. — $G(-Cr^{VI})$ in $K_2Cr_2O_7$ acid solutions.

1) 0.8 N H_2SO_4, $4.8 \cdot 10^{15}$ eV ml^{-1} s^{-1}, γ-rays;
2) 0.8 N H_2SO_4, $1.6 \cdot 10^{18}$ eV $ml^{-1} s^{-1}$, electron-beam;
3) 0.2 N H_2SO_4, $1.6 \cdot 10^{18}$ eV ml^{-1} s^{-1}, electron-beam.

The results show that $G(-Cr^{VI})$ largely exceeds the required stoichiometric value of 1/3 G_{red}, from relation (B).

It is known that in these conditions because of reaction

$$e^-_{aq} + H^+ \rightarrow H \tag{10}$$

we have all reducing species as H atoms.

We repeated the experiment in aerated solutions and the results showed that the presence of O_2 does not only inhibit the reduction of Cr^{VI} but even induce a small increase of $G(-Cr^{VI})$. It is very difficult to explain all these results by H atoms reduction, which only initiate this process:

$$Cr_2O_7^{2-} + H \rightarrow CrO_3^- + CrO_4^{2-} + H^+ \tag{11}$$

We suppose that the Cr^V transient, as CrO_3^-, in these conditions reacts further with water to give rise to a reducing species to develop a chain reduction, as follows:

$$CrO_3^- + H_2O \xrightarrow{H^+} CrO_2 + HO_2 + H_2 \tag{12}$$

$$H_2 + OH \rightarrow H + H_2O \tag{13}$$

The HO_2 and H radicals reduce further the Cr^{VI}, or its transient valence states, until Cr^{III}:

$$Cr^{VI} + HO_2 \rightarrow Cr^V + O_2 + H^+ \tag{14}$$

In this hypothesis the back oxidation by OH radicals can not overcome this chain reduction process even in the absence of any OH scavenger. The dose-rate effect is probably due to the competition between reactions (12) and (8). The last one is faster in electron beam irradiation.

In the presence of oxygen it is possible that the reactions are quite similar because initially HO_2 radical is also formed, as follows :

$$H + O_2 \rightarrow HO_2. \tag{15}$$

In acid solutions, the oxigenated water issuing from radiolysis is also reducing chromium ions :

$$Cr^{VI} + H_2O_2 \rightarrow Cr^{IV} + 2H^+ + O_2 \tag{16}$$

We must say that the unirradiated acid solutions, used in these experiments, did not show any reduction effect of Cr^{VI} ions.

C. METHANOL – AQUEOUS SOLUTIONS

As we expected, using instead of *t*-butanol, another alcohol such as methanol or ethanol, the radiolitic reduction of Cr^{VI} could be higher because of reducing ability of the organic radical formed in reactions (3) and (4).

We investigated in detail the Cr^{VI} reduction, in the presence of methanol, and the obtained results show that $G(-Cr^{VI})$ is higher in both acid and neutral solutions.

In the case of 10^{-3} N K_2CrO_4 neutral solutions, the dependence of G values, of $G(Cr^{VI})$ and $G(H_2)$, on methanol concentration is shown in figure 2.

As we see, both these yields increase with methanol concentration increasing.

Obviously, these results lead us to involve $.CH_2OH$ radical in the reducing mechanism, because only the G_H value and the known reactivity of methanol ($K_{OH} = 6 \cdot 10^8$ mol^{-1} s^{-1} and $K_H = 1.6 \cdot 10^6$ mol^{-1} s^{-1}) cannot explain the above results. If $.CH_2OH$ is unreactive, in neutral solution, for the biggest methanol concentration, the yield of measured hydrogen should obey the following relation :

$$G(H_2) = G_H + G_{H_2} = 1.0 \tag{C}$$

The $G(H_2)$ exceeds the above value, which means that H atom secondary formed *via* reaction (5) is partially scavenged in reaction (4). In this way the radicals H and $.CH_2OH$ develop the chain reduction of chromium ions and H_2 formation.

In acid solutions, as we see in figure 3, the reduction yield is more increasing because of the reaction (12). In these conditions, the chain mechanism is complex because of many reactions involved.

——— $G(-Cr^{VI})$, - - - - $G(H_2)$

1) 0.8 N H_2SO_4, $4.8 \cdot 10^{15}$ eV $ml^{-1}s^{-1}$, γ-rays;
2) and 3) 0.8 N H_2SO_4, $1.6 \cdot 10^{18}$ eV $ml^{-1}s^{-1}$, electron-beam;
4) 0.2 N H_2SO_4, $1.6 \cdot 10^{18}$ eV $ml^{-1}s^{-1}$, electron-beam.

The dose rate and Cr^{VI} concentration effects are even bigger and the $G(H_2)$ increases considerably too.

It can be concluded that the radiolytic reduction of Cr^{VI} by H and e^-_{aq} occurs by a simple, direct mechanism. The reduction yield can be considerably increased using either specific OH scavengers and/or organic additive such as alcohols which generate active reducing radicals and develop chain reactions.

In acid solution the reduction yield is big even in the absence of OH scavengers, owing to water reaction with Cr^{V} transient, which also develops chain reduction of dichromate.

Revue Roumaine de Chimie, 18, 3, 511–517 (1973)

COMPTE RENDU

N. RIEHL. "Einführung in die Lumineszenz" (Introduction to luminiscence), Verlag Karl Thiemig, München, 1971, XV + 351 p.

Luminiscence phenomena are an object of growing interest from the theoretical as well as from the practical point of view. Research work on the emission of light of free atoms and molecules has brought a decisive contribution to the study of their quantic properties and their structure, while the luminiscence of condensed matter has offered important informations on the structure of solid bodies and energy transfer. The mechanism of luminiscence differs according to different types of solid bodies. It is these differences in the mechanism of different luminiscence types which present a major scientific interest and which are at the origin of many practical uses, such as : oscillograph screens, X-Ray lamps, luminiscent dyes, luminiscent plates and diodes, luminiscence microscopy, scintillation detectors, etc.

All these problems would require several volumes to be duely analysed and described, but such a work would soon be obsolete because of the rapid progress achieved in this domain.

The author, with the cooperation of F. Fischer, H. E. Gumlich, E. Krantz, H. Lange, H. Scharmann, A. Schmillen and H. Vogel has got together this compendium, aiming to offer a general information on the main lines of research and use of luminiscence.

The first chapter clarifies the terms of "fluorescence" (when the emission of light ceases immediately after the excitation is stopped) and "phosphorescence" (when it still continues). However, the classification according to the category of luminiscent substance seems better suited and has been adopted by the authors. General information about the composition and obtention of these substances is also to be found in this first chapter. There are two types of substances with luminiscent properties : those with atoms and molecules having own luminiscent properties, and those which acquire these by doping with alien atoms or by lattice flaws. There exists a "cathodic luminiscence", a "photoluminiscence", a "radioluminiscence", an "electroluminiscence" and a "chemiluminiscence", according to the energetic excitation sources bringing about the luminiscence phenomenon. The luminiscence due to flame ("candoluminiscence") and the one due to crystall clivage ("triboluminiscence") are special cases.

The second chapter deals with luminiscent substances of the zinc sulphide group, its activators, and their different properties. The dependence of luminiscence yield upon temperature, energy transfer, behaviour of luminiscent substances with several sorts of activators, absorption and emission spectra, photon interaction, etc. are also studied in this chapter. Finally, the main practical uses of these luminophores are examined and commented upon. The third chapter dwells on luminiscent substances containing oxygen and those of the rare earths group and the way of obtaining them by synthesis reactions in solid phase.

Chapter four is intended to halogenate luminiscent substances and their different uses. As a matter of fact, these were the first fluorescent substances discovered and the name itself comes from fluorit, the mineral first in use in this domain.

"Thermoluminiscence" is treated in chapter five and "Electroluminiscence" in chapter six, while the last chapter deals with the "physical bases of the possibility to apply luminiscence to organic substances". It, therefore, deals with the luminiscent features of fluoresceine, anthracene, phenantren, naphtalene, eosive salicilic acid and their derivates. Their luminiscence qualities are very useful in scintillation techniques and in luminiscent microscopy.

Each chapter ends with a minute speciality bibliography and the whole work is accompanied by an alphabetical index, making it very handy and useful not only to specialists but also to students and technicians.

NOTE POUR LES AUTEURS

La *Revue Roumaine de Chimie* publie des articles en anglais, français, russe, allemand ou espagnol. Les auteurs sont priés d'envoyer des articles, notes, communications et comptes rendus inédits.

Les manuscrits seront dactylographiés à deux intervalles. Les tableaux seront dactylographiés sur feuilles séparées, de même que la légende des figures. Les diagrammes seront tracés à l'encre de Chine sur papier calque. Les tableaux et les figures seront numérotés par des chiffres arabes, en nombre strictement nécessaire. Prière de ne pas inscrire les mêmes données dans les tableaux et les figures. Les formules chimiques seront incluses dans le texte ; en outre, elles seront transcrites sur des feuilles séparées. Les auteurs sont priés d'indiquer les caractères italiques (en soulignant les lettres au crayon), ainsi que tout autre caractère spécial. L'ordre des références bibliographiques sera celui de leur mention dans le texte ; le nom de l'auteur sera précédé de l'initiale du prénom ; les publications périodiques seront présentées suivant les prescriptions internationales. Les références seront ajoutées à la fin de l'article ; elles paraîtront comme des notes, au bas de la page. Le texte sera précédé d'un résumé comprenant 15 lignes au maximum.

L'entière responsabilité du contenu des articles appartient aux auteurs. On publie des articles dus aux collaborateurs roumains ou étrangers. Les auteurs recevront 50 tirés à part.

ON THE MECHANISM OF THE REACTIONS BETWEEN BENZYL BROMIDE AND ALCOHOLS

I.G. MURGULESCU and IOANA DEMETRESCU

The Faculty of Chemistry, Chair of Physical Chemistry, Bd. Republicii 13, Bucharest, Romania

Received October 26, 1972

The results of studying the systems formed by benzyl bromide alcoholysis with normal alcohols[1], primary isoalcohols[2] and secondary alcohols[3] are analysed. The activation parameters of these systems are calculated and the observed compensation effects are discussed accepting a linear correlation of the entropy and enthalpy factors. The results lead to a sequence of reaction mechanisms.

The benzyl halides solvolysis[4–11] has been the subject of numerous kinetic studies but, unfortunately, the obtained results led to contradictory interpretations. To contribute to the elucidation of some ambiguities we have comparatively analysed the results obtained previously in the benzyl bromide alcoholysis with normal, secondary and isoalcohols.

In table 1 we give the values of the activation energy, preexponential factors, free activation entropy, enthalpy and energy, for all studied systems.

One can see that the activation entropies and enthalpies are correlated. Figure 1 shows the compensation effect in the assumption of the isokinetic equation.[12,13]

The isokinetic equation is:

$$\Delta H^{\neq} = \Delta H_0^{\neq} + \beta \Delta S^{\neq} \qquad (1)$$

Table 1

Activation parameters for the $C_6H_5\,CH_2\,Br$ + ROH system

ROH	log *A*	*E*	$\Delta H^{\neq}$	$\Delta S^{\neq}$	$\Delta G^{\neq}$
CH_3OH	12.138	22420	21730	− 5.27	23540
C_2H_5OH	11.480	21500	20820	− 8.29	23660
C_3H_7OH	11.184	21130	20450	− 9.65	23760
C_4H_9OH	10.408	20140	19457	−13.20	24670
iso-C_4H_9OH	10.72	20100	19420	−11.77	23460
iso-C_5H_7OH	9.63	19200	18520	−16.77	24271
iso-$C_8H_{17}OH$	8.55	18500	17810	−21.75	25380
sec-C_3H_7OH	7.77	16500	15820	−25.26	23800
sec-C_4H_9OH	7.068	16200	15510	−28.54	25440

where H_0 is the intercept for $\Delta S^{\neq} = 0$, and β, having the dimensions of a temperature, the slope of the straight line. The equation (1) is called "isokinetic", because putting it in the equation defining the free activation energy,

$$\Delta G^{\neq} = \Delta H^{\neq} - T\Delta S^{\neq} \tag{2}$$

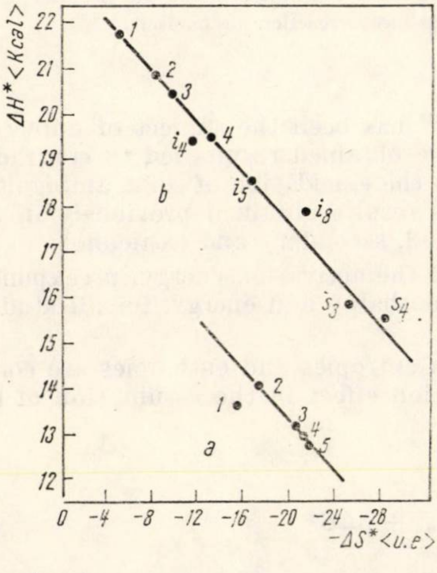

Fig. 1. — Compensation effects for the systems:

a) C_6H_5COCl + ROH;

b) $C_6H_5CH_2Br$ + ROH: 1. CH_3OH; 2. C_2H_5OH; 3. C_3H_7OH; 4. C_4H_9OH; 5. $C_6H_{13}OH$; i_4 = *i*-C_4H_9OH; i_5 = *i*-$C_5H_{11}OH$; i_8 = *i*-$C_8H_{17}OH$; s_3 = sec-C_3H_7OH; s_4 = sec-C_4H_9OH.

we get

$$\Delta G^{\neq} = \Delta H_0^{\neq} + (\beta - T)\,\Delta S^{\neq} \tag{3}$$

and we can see that at $T = \beta$, $\Delta G^{\neq} = \Delta H_0^{\neq}$ = constant; this means that the reactions obeying equation (1) have the same rate at the temperature $T = \beta$.

Related systems verifying an isokinetic equation could be supposed to have a common mechanism. However, such interpretations must be carefully made taking into account the experimental errors affecting the values of both entropy and enthalpy.

As we can see from figure 1, the entropies and enthalpies follow a straight line. The isokinetic temperature is as much as 2°. We also can see that the reactions formed by the alcoholysis of benzoyl chloride[14] have the same isokinetic temperature; this indicates a common mechanism for the alcoholysis of the two compounds. Since for the latter it has been admitted, due to a series of reasons,[15-17] a bimolecular mechanism, we could argue in favour of a bimolecular mechanism in the case of the alcoholysis of benzyl bromide either.

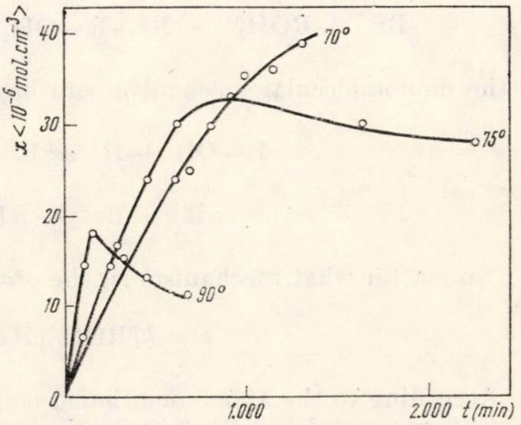

Fig. 2. — Variation of HBr concentration in time for the $C_6H_5CH_2Br + i\text{-}C_8H_{17}OH$ system.

It is interesting to notice that the points having a greater distance from the straight line correspond to alcohols with more carbon atoms in molecule, both in case of isoalcohols and in case of secondary alcohols; in such cases some changes in the kinetic mechanism could have taken place.

These observations were completed by some other experimental facts found in the case of systems with a long reaction time, e.g. in the case of the isooctyl alcohol. In that case we found that the variation in time of the acid concentration shows a maximum (fig. 2). As we have shown in a previous work,[2] at the same time the quantity of water in the system was increasing. The decrease of the acidity was interpreted as being due to the consumption of the acid in a reaction with the alcohol. The reaction between the acid and the alcohol was followed up leading to the conclusion that at a temperature less than 50° it has a negligible weight in the case of alcoholysis reactions finishing in 20 hours at most. Under other conditions, however, it is highly probable that the reaction between acid and alcohol become competitive with the halide alcohol reaction.

---

[14] I. G. Murgulescu and I. Demetrescu, *Rev. Roumaine Chim.* **14**, 149 (1969).
[15] A. Kivinen, *Suomen Kemistilehti B*, **36**, 163 (1963).
[16] A. Kivinen, *Suomen Kemistilehti B*, **38**, 210 (1965).
[17] A. Kivinen and A. Viitala, *Suomen Kemistilehti B*, **40**, 19 (1967).

As the displacement of the halogen is preceded by a rapid equilibrium, bimolecular and unimolecular mechanisms were successively suggested, like in most similar two-step reactions.[18-21]

The bimolecular scheme is represented by the equations :

$$R-OH + H^+ \rightleftarrows ROH_2^+$$

$$Br^- + ROH_2^+ \rightarrow [Br-R-OH_2] \rightarrow Br-R + H_2O$$

and the monomolecular mechanism can be represented by

$$R-OH + H^+ \rightleftarrows R^+ + H_2O$$

$$R^+ + Br^- \rightarrow RBr$$

No matter what mechanism is, the observed kinetics is of the second order

$$v = k[ROH][HBr]$$

According to the above mentioned considerations and to some other arguments presented in a previous work,[2] taking into account the existing results regarding the alcoholysis of benzyl chloride,[9] we consider that the alcoholysis of benzyl bromide is represented by the following sequence of successive reactions

$$C_6H_5-CH_2Br + ROH \rightarrow C_6H_5CH_2OR + H^+Br^-, \qquad (a)$$

a pseudo-monomolecular reaction followed by the acid-alcohol reaction; taking into account the mechanism discussed above, this reaction could be as follows

$$ROH + HBr \overset{fast}{\rightleftarrows} ROH_2^+ + Br \qquad (b)$$

$$ROH_2^+ + Br^- \xrightarrow{slow} RBr + H_2 \qquad (c)$$

2nd order,

or

$$ROH_2^+ \xrightarrow[slow]{} R^+ + H_2O \xrightarrow[fast]{} RBr \qquad (d)$$

1st order

$$RBr + ROH \xrightarrow[very\ slow]{} ROR + HBr \qquad (e)$$

By reactivity reasons the reaction (e) could be neglected as against (c) and (d).

[20] E. Grunwald and S. Winstein, *J. Amer. Chem. Soc.*, **69**, 2051 (1947).

[21] M. Bennett and F. Reynolds, *J. Chem. Soc.*, **1935**, 131.

The equilibrium

$$ROH_2^+ + H_2O \underset{2}{\overset{1}{\rightleftarrows}} H_3O^+ + ROH$$

could also exist, reflecting the competition of nucleophylic effects of water and alcohol.

The above image would correspond theoretically to any system formed by benzyl bromide and alcohols, for any alcohol. Examining the rate constants at various conversions [1,2,3] for the same system in the same temperature conditions, a diminution of the rate constant can be observed beginning at advanced conversion. This limit from which the diminution of the rate constant exceeds the experimental errors, changes from one alcohol to another, decreasing as the chain of the alcohol grows longer; our experimental data indicate that for the systems formed with alcohols having more than 4–5 carbon atoms, the reaction between acid and alcohol has an important contribution.

As regards the formal kinetic solution of this problem, according to some approximations already used for similar cases [22] only the reaction (a) of the sequence was taken into account, except for the system with isooctyl alcohol.

In the case of this alcohol we chose a method starting with the integration of the rate equation. [9]

If a is the initial concentration of benzyl bromide, y the concentration of octyl bromide and x the concentration of the acid, the rate equation will be

$$\frac{dx}{dt} = k_1(a - x - y) - k_2x^2 \tag{3}$$

This equation describes correctly the variation of the concentration in the sequence of reactions which is schematically:

$$\begin{array}{l} C_6H_5CH_2Br + ROH \xrightarrow{k_1} C_6H_5CH_2OR + H^+Br^- \\ (a - x - y) \end{array}$$

$$Br^- + ROH_2^+ \xrightarrow{k_2} RBr + H_2O$$

The solution of the equation is not a simple one.
The equation can be put in the form

$$\frac{dx/dt}{a - x - y} = k_1 - \frac{k_2x^2}{a - x - y} \tag{4}$$

which allows a very convenient graphically solving, using the straight line

$$\frac{dx/dt}{a - x} = f\left(\frac{x^2}{a - x}\right) \tag{5}$$

---

[22] D. Roberts, H. Young and S. Winstein, *J. Amer. Chem. Soc.*, **64** 2157 (1942).

In this way we use only that part of the curve of the variation of the acid concentration in time for which y is negligible (the part before the maximum in fig. 2); the straight line obtained has the slope $-k_2$ and the intercept for $\left(\frac{x^2}{a-x}\right) = 0, k_1$. The obtained values are given in table 2.

Table 2

The rate constants k_1 and $k'_2 = k_2/b$ for the $C_6H_5CH_2Br + i\text{-}C_8H_{17}OH$ system

k ($s^{-1}\,mol^{-1}cm^3$)	70°	75°	90°
k_1	$7.06 \cdot 10^{-4}$	$9.90 \cdot 10^{-4}$	$26.3 \cdot 10^{-4}$
k'_2	$1.94 \cdot 10^{-1}$	$2.89 \cdot 10^{-1}$	3.74

Plotting log k versus $1/T$ allows the calculation of the following values for the activation parameters

$$E = 16\,110 \text{ cal} \qquad E = 37\,730 \text{ cal}$$

$$\Delta S^{\neq} = -24.30 \text{ cal/degree}$$

$$\Delta H^{\neq} = 15\,530 \text{ cal}$$

$$\Delta G^{\neq} = 23\,990 \text{ cal}$$

The activation energy E_2 of the reaction between the solvent and hydrobromic acid indicates that this reaction is strongly affected by temperature, which is to be expected if the evolution of the curves in fig. 2 is taken into account. This value fully agrees with the activation energies given in the literature for the reactions between acid and alcohol.[9,23] Correspondingly the values of k_2 given for the alcoholysis of benzyl chloride by methyl alcohol[9] ($k'_2 = 4.75\ s^{-1}mol^{-1}\,cm^3$ at 80°, $k'_2 = 1.50\ s^{-1}mol^{-1}\,cm^3$ at 70° and $4.2 \times 10^{-1} s^{-1}mol^{-1}\,cm^3$ at 60°) are of the same order of magnitude and lead to comparable activation energies.

The interpretation of the benzyl halides alcoholysis as a sequence of reactions explains the diminution tendency of rate constant in these systems observed in other kinetic studies. Therefore, this diminution cannot be interpreted as a mass law effect and cannot be an argument for a unimolecular mechanism; moreover, the older hypothesis, according to which benzyl compounds have the tendency to react according to SN_1 substitutions, was lately infirmed.

---

[23] C. Hinshelwood, *J. Chem. Soc.*, **1935**, 599.

Studying the variation of the activation entropy and of the ratio between the activation heat capacity and the activation entropy, $\Delta C^{\neq}/\Delta S^{\neq}$, for SN_1 and SN mechanisms, Kohnstam suggested this ratio as criterion for the mechanism: from known activation entropies for SN_1 and SN_2 reactions and from the $\Delta S^{\neq}$ value observed at substitution in benzyl halide undergoing solvolysis, he calculated the solvolytic percent of SN_1 and SN_2.

In the majority of cases fractional part of SN_2 was much greater than that of SN_1.

Isotopic exchange of benzyl chloride with chlorine follows also an SN_2 mechanism.

In spite of literature contradictions, we consider that the solvolysis benzyl halides in alcoholic medium are complex bimolecular reactions.

Received November 4, 1972

The NMR spectra of 10,10 – and 2,8-substituted derivatives of phenoxatellurine are given and discussed. The deshielding of the protons at the 1,9 sites evidences charge modifications in the benzene rings which are accounted for by semi-empirical MO-calculations.

The previous papers [1,2] were concerned with the electronic spectra and CT-complexes of phenoxatellurine and its derivatives. It is well known that the electronic spectra furnish information especially on the energy levels of the molecule. The charge distribution in the ground state and its change under the influence of solvents or substituents are better reflected, according to several authors [3,4] by the proton chemical shifts in the NMR spectra. Therefore, the object of this paper is to present the NMR spectra of phenoxatellurine and some disubstituted derivatives and to correlate them with changes of the charge distribution in the heterocycle.

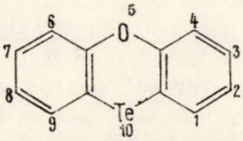

Fig. 1. — The numbering used in this paper.

EXPERIMENTAL PART

The compounds contained in Table 1 (numbering as in fig. 1) were synthetized by literature methods.[5-8] Their NMR spectra were recorded at a HNM–C 60–HL Spectrometer at 60 Mc and a TESLA–487 B Spectrometer at 80 Mc, in $CDCl_3$ and DMSO–d_6 with TMS as internal standard.

A general remark made throughout this work was that excepting the fluoro-compounds, the 2,8-disubstituted derivatives give uncompletely resolved spectra. It was firstly thought this could be due to their poor solubility in the solvents used; therefore, $SOCl_2$ was also employed for 2,8-dimethyl, 10,10-dichlorophenoxatellurine, but in spite of the better solubility in this solvent, the resolution was not improved. In the case of the 2,8-dimethyl derivatives the broadening of the signals of the 1,9 and 3,7 protons could be due, according to Pople, [9] to the unresolved quartet determined by the interaction with the methyl protons.

* In our previous work [1] the melting point of this compound appeared erroneous. The real value is m.p. = 75–76°.

RESULTS AND DISCUSSION

From all the compounds studied only the spectrum of phenoxatellurine was recently mentioned in literature by Calder *et al.* [10]. These authors remark the greater solvent dependence of two protons and, by analogy with similar compounds, assign their chemical shifts to the 1, 9 positions (fig. 1). Our results for the unsubstituted phenoxatellurine are in good agreement with this statement, pointing out a shift of the signal of these protons from 7.49 ppm in $CDCl_3$ to 7.62 ppm in DMSO-d_6.

As the NMR spectra of the phenoxatellurine derivatives are dependent on the substituent position, they will be discussed separately in function of the site of substitution.

A. TELLURIUM – SUBSTITUTED DERIVATIVES

As it was pointed out by Balkau, Fuller and Heffernan [11] the usefulness of the electronegative substituted derivatives (at the heteroatom) in helping to assign the spectrum of the parent compound lay in the possibility that only H_1 and H_9 might be severely displaced, the remaining protons being fairly remote from the site of substitution.

In order to check this, the spectrum of 10,10-diiodophenoxatellurine was analysed in the ABCX approximation and the results compared to those of Calder *et al.* for the parent compound.

10,10-Diiodo-phenoxatellurine	8.003	7.19	7.43	7.36	7.60	1.50	0.40	7.50	1.50	8.20	DMSO-d_6
10,10-Dichlorophenoxatellurine	8.14	—	—	—	—	—	—	—	—	—	,,

As may be seen from fig. 2b the poor resolution of the spectrum of the 10,10-dichloroderivative prevented the analysis of the whole spectrum, so that only $\delta_{1,9}$ could be determined. It is visible from Table 2 that two protons in the molecule are strongly deshielded by the electronegative substitution at the tellurium atom. We consider this to be a valid argument for the assignment of the low fields signal to the 1,9 positions. The fact that their chemical shifts are in the order of electronegativity of the halogens supports the idea that the modification of the NMR spectrum on the 10,10-substitution is primarily due to inductive effects.

B. RING - SUBSTITUTED DERIVATIVES

The relevant chemical shifts of the 2,8 and simultaneously 2,8-10,10-substituted derivatives are contained in Table 3. As may be observed, the

Table 3

Approximate parameters^a) of the proton resonance spectra of the 2,8- and 10,10-substituted phenoxatellurines

Compound	δ_1	δ_3	δ_4	J_{12}	J_{13}	J_{14}	J_{23}	J_{24}	J_{34}	Compound	$\delta_{1,9}$
2,8-Difluoro-phenoxatellurine	7.48	5.05	7.18	7.6	2.5	0.6	7.5	2.4	8.5	2,8-Dimethyl-phenoxatellurine ($CDCl_3$)	7.20
2,8-Difluoro-10,10-diiodo-phenoxatellurine^b)	7.75	—	—	—	—	—	—	—	—	2,8-Dimethyl-10,10-dibrom-phenoxatellurine ($CDCl_3$)	7.64
2,8-Difluoro-10,10-dichloro-phenoxatellurine	7.89	7.38	7.50	7.5	2.3	0.6	7.5	2.4	8.5	2,8-Dimethyl-10,10-dichlorophenoxatellurine	7.98

a) The spectra of the simultaneously 2,8- and 10,10-substituted derivatives were analysed in the ABMX approximation which accounts satisfactorily for the observed spectrum.

b) The spectrum of 2,8-difluoro-10,10-diiodophenoxatellurine in DMSO is an example of "deceivingly simple' spectrum of ABMX type (4 lines) and only the chemical shift of the 1,9 protons could be determined.

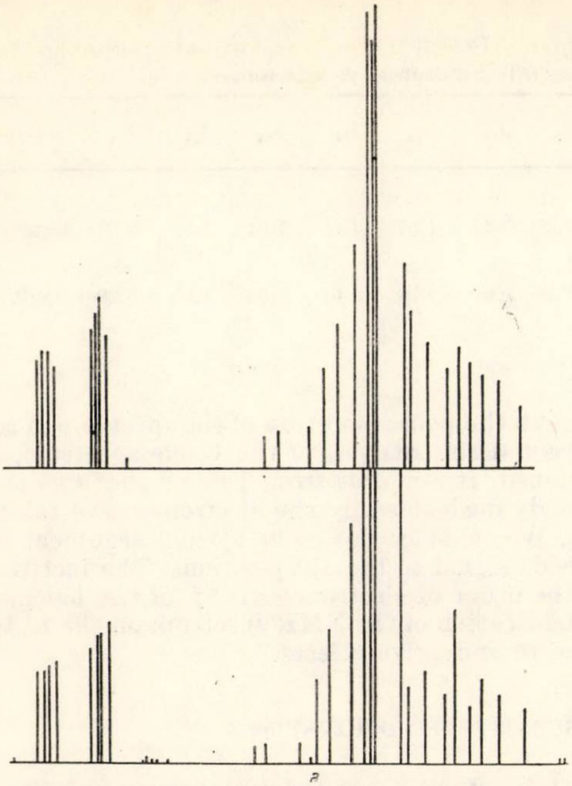

Fig. 2a. – Spectrum of 10,10-diiodophenoxatellurine in DMSO : experimental (upper spectrum) and calculated with the parameters contained in Table 2 (down).

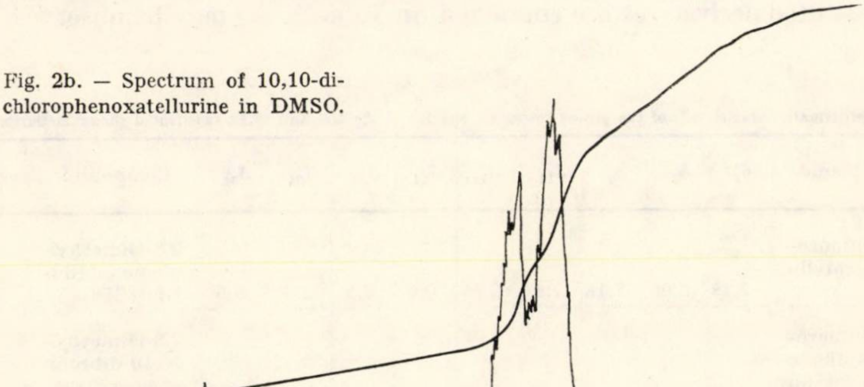

Fig. 2b. – Spectrum of 10,10-dichlorophenoxatellurine in DMSO.

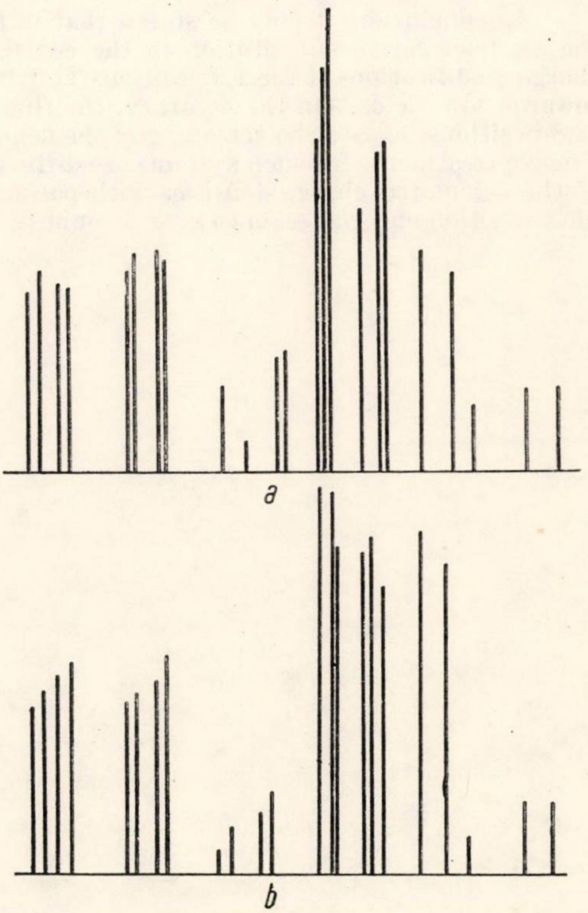
2,8-substitution with fluorine and methyl shifts the 1,9 protons to higher fields *vs*. those of the parent compound. The effect of the electronegative 10,10-substitution discussed before is also evident for simultaneously 2,8-and 10,10-substituted compounds.

Several authors [3,4] think that a quantitative correlation may be established between the excess charge on the carbon atoms, Δq, and the shift of the proton bound to it, δ. Although the precise form of such a relationship is still discussed, many authors think it holds also for heterocyclic molecules. The system studied is of course too large and there are few data about the tellurium atom in organic compounds to permit the development of any quantitative dependence.

Fig. 3. — Experimental (a) and calculated (b) spectrum (parameters from Table 3) of 2,8-difluorophenoxatellurine.



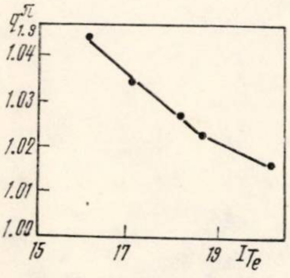


Fig. 4. — The dependence of the π-charge density of the 1,9 positions (calculated SCF — PPP) on the ionization potential of the tellurium atom.

However, semi-empirical SCF-MO calculations in the frame of the Pariser-Parr-Pople method were performed; basic assumptions and choice of parameters are discussed elsewhere [12], in connection to the electronic spectra. It was supposed that the electronegative substitution at the tellurium atom will enhance its ionization potential and it was found that the most sensitive were the 1,9 positions.

Fig. 4 shows a regular decrease of the 1,9-charge density with the increasing I. P. of the tellurium atom. This decrease is parallel to the observed shift towards low fields of the 1,9 protons on the electronegative substitution at the tellurium atom.

In conclusion, it may be stated that in the case of phenoxatellurine the electronegative substitution in the central ring brings about greater charge modifications at the 1,9 positions, shifting the signal of these protons towards low fields. On the contrary, the fluoro-substitution in the rings (2,8-positions) causes the screening of the neighbouring 1,9 protons. Quantitative treatments for such systems are difficult to perform but the trends of the calculated charge densities with parameters calibrated for electronic transition energies seem to give account for the observed shifts.

METHYL RADICALS ON POROUS VYCOR GLASS AS STUDIED BY ESR SPECTROSCOPY

D. P. LAZĂR* and JOHN TURKEVICH**

* Physical Chemistry Department "Al. I. Cuza" University, Jassy, Calea 23 August nr. 11, Romania

** Frick Chemical Laboratory, Princeton University, Princeton, New Jersey, U.S.A.

Received January 28, 1972

The practical procedures for preparing methyl radicals from methyl iodide adsorbed on porous Vycor glass are presented; then the ESR spectra of the methyl radical are in detail described following both temperature and microwaves-power influence on the methyl radicals decay. Chemical treatment of the glass support and its influence on the methyl radical lifetime are also reported.

EXPERIMENTAL PROCEDURE

Methyl radicals were prepared by u.v. light irradiation at liquid nitrogen temperature of methyl iodide adsorbed on porous Vycor glass rods (Vycor glass rods were of 1.5 mm diameter and 20 mm long, 40 Å pores size, Corning nr. 7930). The irradiation was carried out with a low pressure mercury lamp (110 volts input 5,000 volts output, 500 watts power) at a distance of 2 to 3 cm from the quartz tube containing Vycor rod sample which was, as a preliminary, immersed into a Dewar vessel (suitable for ESR measurements) filled with liquid nitrogen. The ESR Dewar vessel used for u.v. light irradiation was similar to the one used for the proper measurements, i.e. having a long transparent quartz tube at the bottom. Irradiation was carried out in a ESR Dewar vessel different from the one used for measurements to avoid the signals generated by the u.v. irradiation in the quartz of the ESR Dewar vessel.

The quartz used for the sample tubes containing Vycor samples, as well the Vycor glass, did not develop a signal on irradiation. After irradiation, the sample tube, having in a Vycor glass rod, was rapidly transferred (to avoid iceing) from one Dewar vessel filled with liquid nitrogen to the other Dewar vessel also containing liquid nitrogen.

To record ESR spectra, a VARIAN Spectrometer Md. V. 4500 operating at 9.5 kcycles/s, with a multi-purpose cavity mode TE_{102} was employed; the magnetic field was modulated at 100 KHz and was controlled by a Field Dial regulator V–FR 2200. All ESR measurements were made at liquid nitrogen temperature, except for cases when the temperature rise influence, was studied.

The Vycor glass rods, as received, were first treated with concentrated nitric acid, then with distilled water and heated in vacuum for 10–12 hours at 600°. Some of the Vycor samples were treated for 12 hours at room temperature with aqueous sodium tetraborate solutions (2.00 %–0.2 % – 0.1 % and 0.05 %) and others were treated with aqueous solutions of hydrogen fluoride (0.5 %–0.35 % – 0.25 % and 0.1 %).

Treatment with HF solutions having concentrations greater than 0.5% caused decrease in the size of the Vycor rods used.

The Vycor samples were placed in quartz tubes suitable for ESR measurements and these tubes were sealed through quartz-pyrex graded seals to stopcocks having standard tape joints which permitted attachment to a conventional vacuum system.

The sample was pumped off for at least 12 hours at 600° using a mercury diffusion pump; it was then cooled down in vacuum to room temperature; after this the sample was contacted for 2 minutes with vapours of freshly distilled methyl iodide at room temperature. After methyl iodide adsorption, the sample was pumped off for 15 minutes at room temperature, then transferred to the quartz Dewar vessel filled with liquid nitrogen and irradiated with u.v. light. Unless otherwise stated, the u.v. irradiation time was 15 minutes.

RESULTS

The ESR spectrum of the methyl radical consisted of four strong sharp lines centered at $g = 2$, each line having satellites. Frequently, 2 additional lines due to hydrogen atoms were observed.

The four sharp methyl radical lines have a separation of 22.1 G, which was constant to 1% in a given hyperfine complex structure and varied from measurement to measurement by at most 2%.

The intensities of lines under normal measurement conditions (microwaves power attenuation = 10 dB; modulation amplitude of 1.5 gauss; scan: 500 G/10 min) were in the ratio of 1.00/3.76/4.07/1.28 for magnetic field values of 3185.5/3214.7/3235.4/3251.1 G.

This result is in good agreement with the ratio 1.0/3.7/4.1/1.3 previously reported by Turkevich and Fujita. [1]

These former values markedly differ from the theoretical values of 1.0/3.0/3.0/1.0 experimentally confirmed for the methyl radical in aqueous solution by Turkevich and Mickevich. [2]

The line-width was 2.8 G, a value previously reported by Turkevich and Fujita [1] for the methyl radical on silica and, therefore, much wider than the value of 1.2 G found by Turkevich and Mickevich [2] for the methyl radical in solution.

Measurements were carried out to determine the effect of microwaves power and modulation amplitude on the intensity and width of the hyperfine structure. It was found that at 15 dB power attenuation the modulation amplitude has a large effect on the line intensities.

As is shown in Table 1, lines 1 and 2 (numbered from the lower field side) exhibit a maximum intensity at modulation 400 (= 1.5 G) while lines 3 and 4 at modulation 300 (= 1.2 G).

Distorsion of the lines was observed if the modulation amplitude was increased above 600 (= 2.25 G).

20	1425.00	4670.00	4255.00	1115.00	1.28	4.19	3.82	1
25	830.00	2950.00	2575.00	695.00	1.19	4.24	3.71	1

Conditions : F = 3205 G ; Sc = 500 G/10 min; L = 100 ; R = 2 ; T = 196°C; U.V. time = 5 hrs untreated Vycor rod.

The influence of microwaves power was determined both at modulation 400 and modulation 10 (= 0.375 G). At modulation 400, the hyperfine line of the spectrum seems to saturate at powers greater than 15 dB setting.

Table 3

Influence of the microwaves power (Modulation = 10).

	25		201.00	10.80	116.64	23.445

Conditions: Sc = 10 G/10 min.; $R = 1$; $L = 100$
$T = -196$°C; u.v. time = 6 hrs
untreated Vycor rod.

At modulation 10 the saturation effect starts at powers greater than 20 dB.

The width of the lines decrease in all cases with power, being 402 mili-gauss at the lowest power and modulation used.

The intensities of the four lines of the hyperfine spectrum are seriously different depending on the modulation amplitude, the best line-ratios being those which were observed at higher modulations. Measurements at 35 KHz/s, attenuation of 15 dB and modulation of 20 (= 0.75 G) gave the same spacing between the hyperfine lines as was obtained at 9.5 KHz/s when a ratio of line intensities of 1.0/2.75/2.37/0.73 was obtained. The line width was of 2.0 G.

In addition to the four main peaks of methyl radical spectrum (Fig. 1), nine satellite-peaks were observed. Eight of these satellites can be divided into two groups symmetrically placed around the main peaks.

The separation between the two outermost peaks is of 76.26 G while the separation between the penultimate lines of the main peaks of the methyl radical spectrum is of 71.46 G, resulting a difference of 4.80 G between the above given values. We assign these eight satellite peaks to a splitting produced in the main peaks by the natural abundance of C^{13} isotope. Turkevich and Fujita [1] found a difference of 38.5 G but using 55% enriched C^{13}, and characterized the methyl group as being a planar free-moving radical. On the basis of our present results, we must conclude that the methyl group is a planar radical rotating around the axis perpendicular to the plane. [3]

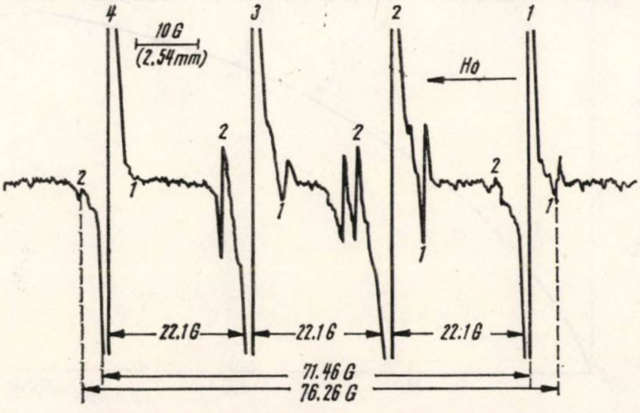

Fig. 1. — Electron spin resonance spectrum of methyl radicals from the U.V. light photolysis of methyl iodide on porous Vycor glass ($T = -196°C$).

Conditions: $F = 3205$ G; Sc = 1 KG/100 min; Att = 10 dB; Md = 10; $R = 2$; $L = 1\,000$; U. V. time = 6 hrs; untreated Vycor; Chart speed = 2.54 cm/min; Chart calibration: 1 cm = 3.937 G).

No peaks were found at a difference of 38.5 G characteristic for a planar free moving methyl radical nor at 300 G characteristic for a tetrahedral configuration of CH_3 radical.

The difference between our present results and that reported by Turkevich and Fujita [1] must be ascribed to the higher concentration of methyl radicals used in the present work and hence to the scarcity of methyl radicals (2% from the possible maximum concentration of methyl radicals) in the Turkevich-Fujita experiments.

The separation between the four peaks of the first group of satellite-lines is of 22.8/19.8/24.2 G, and 22.1/22.0/22.1 G respectively, for the second group, while the main peaks separations are of 22.1 G.

The intensity of the satellite-lines was about 1% of the second line of the main spectrum when for the C^{13} abundance it should be of 0.5%, since in the ESR methyl spectrum there are two C^{13} lines for each C^{12}

[3] Ţ. Cole, H. O. Pritchard, N. R. Davidson and H. M. Mc. Conell, *Mol. Phys.*, **1**, 406 (1958).

line. The ninth satellite-peak [*] was observed at a distance of 7.33 G from the peak number 2 on the low field side. Peak 2 (main spectrum) also shows a shoulder on each side separated by 4.2 G [**].

Very often a hydrogen atom spectrum consisting of two lines separated by 491 G was recorded and having an intensity of 0.4% of the smallest methyl peaks. Its lines were very sharp being 0.4 G at 25 dB power attenuation and for a field modulation of 0.1 G.

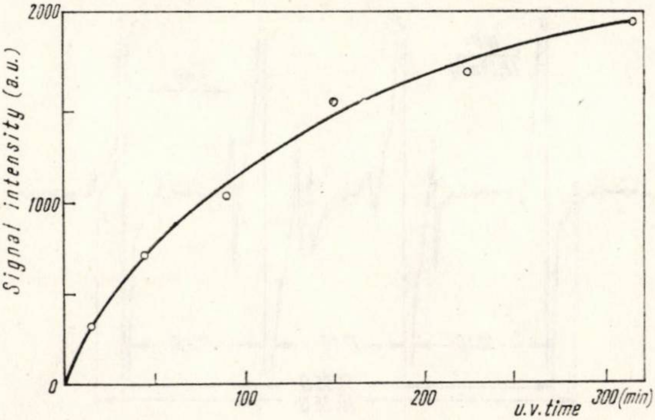

Fig. 2. – Influence of U.V. irradiation time (untreated Vycor rod).

The hydrogen spectrum saturated very easily and the above given value of the line-width may be an upper limit.

A small asymmetric signal was observed at $g = 4$.

U.V. time irradiation effect. The intensity of the ESR signal rose steadily with that of irradiation and, as Fig. 2 shows, approaches a limiting value when the opposite reaction

$$CH_3I \rightleftharpoons CH_3 + I \qquad (1)$$

reaches the equilibrium state. It should be noted that the signal after fifteen minutes u.v. irradiation was easily measured at a level of amplification of 40 and after 315 minutes u.v. irradiation at a level of 5. A level of 2 000 could be used before the noise of the instrument interfers with the methyl signals.

DECAY OF THE METHYL RADICALS AS A FUNCTION OF TEMPERATURE

The ESR signal of the methyl radicals decays as the temperature is raised from the liquid nitrogen temperature to room temperature, where the equilibrium of the opposite reaction (1) is shiften to the left, restoring the initial product. The procedure consisted in keeping the sample at liquid nitrogen temperature in a Dewar flask (filled with liquid nitrogen), then bringing it into a hole of a cylindrical aluminium block (placed into another Dewar flask) cooled to the desired temperature with liquid nitrogen. The temperature of the aluminium block was controlled with a calibrated chromell-alumel thermocouple.

---

[*] The ninth satellite is due to the Dewar vessel.

[**] These shoulders cannot be seen in Fig. 1.

The sample was kept at a certain fixed temperature for at least ten minutes (thermostation time interval) just sufficient to allow thermal equilibrium between sample and aluminium block and then again brought into the ESR Dewar to the temperature of liquid nitrogen for measurements. Experiments showed that at a given temperature the decrease of the ESR signal takes place very rapidly, perhaps in less then the ten minutes used as the measurement time interval, then the ESR signal decreases slowly with time as Fig. 3 shows.

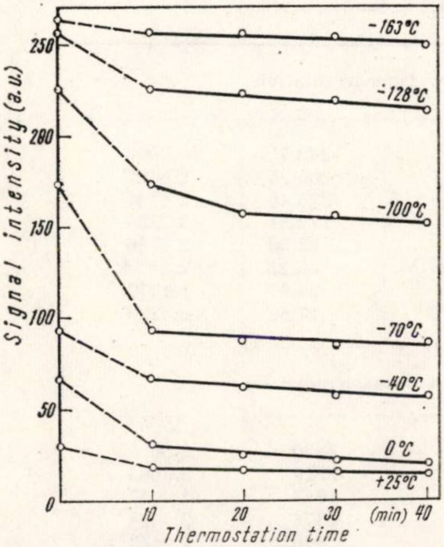

Fig. 3. – Curves of temperature and time decay of methyl radicals after fifteen minutes U.V. irradiation.

(Conditions: $F=3205$ G; $Sc=500$ G/10 min; $L=100$; $R=2$; Att$=15$ dB; untreated Vycor rod (see also the footnote under Table 4).

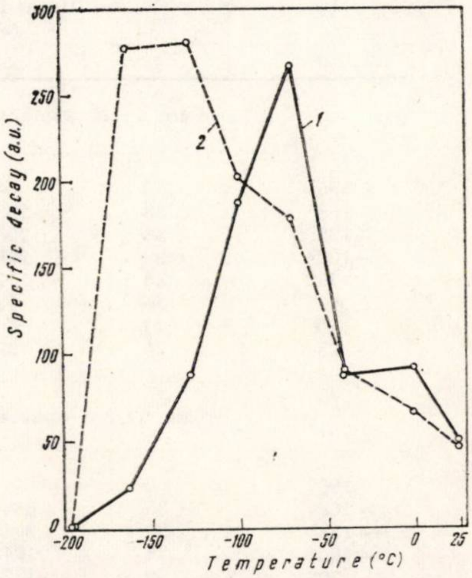

Fig. 4. – Specific decay of methyl radicals concentration for two distinct cases: 15 and 315 minutes U.V. time irradiation, respectively.

(Note: specific decay for 15 min U.V. time irradiation is ten times smaller than the specific decay for 315 min U.V. time irradiation).

Conditions: the same as for Fig. 3

Legend: *1*, full line = 15 min U.V. time; *2*, dotted line = 315 min U.V. time.

The main diminution of the signal takes place within the shortest time interval for measurements (namely in the first ten minutes). If we plot this decrease as a function of temperature we find that the greatest drop of the methyl radical concentration occurs at about − 70°. There is a discontinuity in the evolution of the decay process in the temperature range between − 70° and + 25°, this diminution having, as it seems to us, a periodical character (Fig. 4).

Table 4

Temperature and time decay of methyl radicals for two distinct cases : a/15 minutes u.v. irradiation b/315 u.v. time irradiation

Temp. °C	T °C	Reference signal intensity (a.u.)	Signal intensity (a.u.)	Specific decay $\frac{100-\Delta.10^2}{T}$
0	1	2	3	4
Case a : 15 minutes u.v. time irradiation				
−196°	0	—	263.75	0.0000
−163°	33	263.75	256.25	2.9327
−128°	33	256.25	225.40	2.5131
−100°	28	225.40	172.51	2.7335
− 70°	30	172.51	92.50	2.1736
40°	30	92.50	66.25	2.3873
0°	40	66.25	29.87	1.1272
+ 25	25	21.87	17.62	2.5296
Case b : 315 minutes u.v. time irradiation				
−196°	0	—	3830	0.00
−163°	33	3830	2919	2.3093
−128°	35	2919	1943	1.9017
−100°	28	1943	1378	2.5328
− 70°	30	1378	846	2.0463
− 40°	30	846	580	2.2223
− 0°	40	580	332	1.4310
+ 25	25	332	217	2.6144

Conditions : $F = 3205$ G; Sc : 500 G/10 min; L = 100; $R = 2$;
Att = 15 dB; untreated Vycor rod.
(Sample was kept for ten minutes at each temperature).

Note : $\Delta = \frac{\text{col } 2 - \text{col } 3}{\text{col } 2}$

An increase in the initial methyl radical concentration by increasing the u. v. light irradiation time (up to 315 minutes) from the value usually used as reference (337 arbitrary units for the ESR signal at − 196°) up to 3830 arbitrary units, leads to a more prominent decay at temperatures below − 100° and diminishes this decay at higher temperatures (− 100° to + 25°).

Influence of the chemical treatment on the methyl radical lifetime. Attempts were made to increase the stability of the methyl radicals into the Vycor glass pores by means of pretreatment with aqueous solutions (of different concentrations) of sodium tetraborate and hydrogen fluoride (treatment using Teflon provided no satisfactory results). Treatment with aqueous solutions of sodium tetraborate of various concentrations followed by a fifteen minutes u.v. time irradiation, produced the methyl radical amounts tabulated in Table 5.

The treatment with aqueous solutions of sodium tetraborate (0.1% — 0.2%) provided an increase of methyl radical concentration (compared

Table 5

Influence of treatment with sodium tetraborate (aq.sol) and the corresponding temperature decay

Sodium tetraborate (aq.sol) %	Signal intensity as function of temperature (a.u.).				
	$-196°$	$-130°$	$-65°$	$0°$	$+25°$
2.00	183.00	91.00	45.00	23.00	7.00
0.20	410.00	88.00	38.00	27.00	15.00
0.10	572.00	275.00	114.00	40.00	29.00
0.05	126.00	81.00	37.00	14.00	9.00
untreated Vycor as reference sample	337.00	162.00	64.00	21.00	10.00

Conditions : $F = 3205$ G; Sc = 500 G/10 min
Att = 10 dB (15 dB for 0.2%)
$L = 100$; Md = 400; R = 2
u.v. time = 15 min; untreated Vycor rod.
(Sample was kept for 60 minutes at each temperature).

with methyl radical concentration on untreated Vycor glass) and also a more rapid diminution of methyl radicals concentration as temperature rose (Fig.5).

Table 6

Influence of treatment with hydrogen fluoride (aq.sol) and corresponding temperature decay

Hydrogen fluoride (aq.sol) %	Signal intensity as function of temperature (a.u.).				
	$-196°$	$-130°$	$-65°$	$0°$	$+25°$
0.50	220	96	44	15	7
0.35	440	203	89	25	15
0.25	309	167	72	25	14
0.10	241	118	53	16	10
untreated Vycor rod as reference	337	162	64	21	10

Conditions : $F = 3205$ G; Sc = 500 G/10 min;
Att = 10 dB; Md = 400; $R = 2$;
$L = 100$; u.v. time = 15 min
(sample was kept for 60 minutes at eaoh temperature).

The treatment with aqueous solutions of hydrogen fluoride solutions produced the folowing quantities of free methyl radicals tabulated in Table 6 and plotted in Fig. 6.

Thus, the treatment of Vycor rods with 0.35% H F aqueous solution produced the largest quantity of methyl radicals. The decay curves for the

−160°	10	23.60
−125°	10	12.90
−100°	10	7.46
− 70°	10	4.43
− 40°	10	signal disappeared

Conditions: **F = 3205 G; Sc = 500 G/10 min; Att = 15 dB; R = 2; L = 100; γ-rays irradiation time = 12 hrs at liquid nitrogen temperature; untreated Vycor rod.**

methyl radicals concentrations on treated Vycor rods are similar and exhibit a broad maximum between −130 °C and 0°C (Fig. 5 and Fig. 6).

Methyl iodide irradiated for 24 hours at liquid nitrogen temperature with γ-rays from a Co^{60} source gave a ESR signal of 86 arbitrary units. The lifetime decay of the methyl radicals during this experiment is illustrated on Table 7.

Methyl bromide was found to be a poorer source of methyl radicals (compared with methyl iodide) giving a signal of 42 arbitrary units where the methyl iodide gave a signal of 572 arbitrary units (under the same experimental conditions).

Attempts to get methyl radicals directly captured on Vycor glass from methane gas using electrical discharges gave no satisfactory results.

KINETICS AND MECHANISM OF THE THERMAL DECOMPOSITION OF AZIBENZYL. I

DECOMPOSITION IN BENZENE SOLUTION

M. CONTINEANU*, TATIANA ONCESCU* and R. N. SCHINDLER**

Received September 9, 1972

The thermal decomposition of azibenzyl in benzene solution was studied by gas chromatographic determination of the N_2 evolved during the reaction and by following the change in azibenzyl absorption at $\lambda = 320$ nm. Kinetic evaluation of the data indicate that the decomposition can be described as a unimolecular process with an activation energy of 26.5 Kcal/mole. A pre-exponential coefficient $A \approx 10^{14}$ sec^{-1} and an activation entropy $\Delta S^* = 3$ e.u. are calculated for the process.

INTRODUCTION

The present paper deals with the decomposition kinetics of azibenzyl (known also as Phenyl-benzoyl-diazomethane or Diazodesoxybenzoine) in the inert solvent benzene. The kinetic parameters were determined by means of the spectrophotometric as well as chromatographic technique. They permitted to evaluate the reaction mechanism of this thermal decomposition.

Numerous papers have dealt with the study of the reactivity of diazocarbene compounds in different media.[1-9] The high reactivity of this group of substances has been found useful both in preparative organic chemistry and in the development of theoretical interpretations of reactions in which these compounds occur.

The formation of diphenylketene by heating a benzene solution of azibenzyl to 60° was long ago mentioned by Schröter.[10]

The reaction mechanism is known as Wolff's rearrangement.[11]

The thermolytic, photolytic and catalytic (with copper powder or silver ions) decomposition cause the elimination of N_2 from the azibenzyl molecule with the formation of the intermediate α-ketocarbenic radical. This intermediate forms diphenylketene through an intermolecular rearrangement when the reaction takes place in inert solvents.[10,12] Under these conditions the diphenylketene can be isolated. There is a competition between the rearrangement and different capture processes when working in solvents which capture the α-ketocarbenic radical.[13]

EXPERIMENTAL

Azibenzyl was prepared by oxidizing the corresponding hydrazone.[14]

1st Technique : The thermal decomposition of azibenzyl in benzene was carried out in a cell as shown in figure 1.

The cell containing 5 ml solution (3×10^{-2} m/l) under investigation was introduced into liquid N_2 and a stream of helium was passed through, to remove the air from the installation. After this, the tap R_2 in figure 1 is turned so that helium under a pressure of 1.2 atm flows as carrier gas to a Perkin Elmer F_6 Chromatograph and the four-way tap R_1 is turned to separate cell and chromatograph.

The cell was introduced into a thermostat and the N_2 evolved in the reaction was measured chromatographically as function of reaction time. Experiments were carried out for the temperatures in the 55° – 32.5° range.

The value of the rate constants obtained in this way shows errors which increase with temperature. Consequently we adopted another technique.

2nd Technique : In this case the cell shown in figure 2a was used.

5 ml of azibenzyl solution were introduced at *A* into the cell, which was then cooled to −193° and evacuated through joint *A*.

At the point marked I in figure 2a, the cell was sealed off by flame melting. The cell thus evacuated was placed in the thermostat at the working temperature for a certain time. Through the joints *S* and *S'*, the cell was connected to the same chromatograph tap R_2, as can be seen from figure 2b.

The cell tap was washed with helium, brought from outside, then R_2 was turned so that the carrier gas helium could flow through the cell tap.

From the beginning two short iron bars (*M*, *M'*) were introduced into the cell (figure 2a), which can be actioned from outside by a magnet in order to break the two pointed ends *P* and *P'* of the cell. In this way, the connection with the rest of the cell is achieved. The working temperatures for these experiments were 40°, 50°, 60° and 70°, respectively.

For the two chromatographic techniques we used a column made in laboratory of 1.5 m and $\Phi_i = 5$ mm, filled with molecular sieve of 5 Å.

to study the decomposition of azibenzyl in benzene solution at temperatures of 40°, 50°, 60° and 70°, respectively.

RESULTS

In the chromatographic experiments the number of N_2 moles was determined by a previously calibration with pure nitrogen which was introduced into the chromatograph at known pressures. If we denote by n_{N_2} and n_A respectively, the numbers of N_2 and azibenzyl moles, at time t, then the rate of N_2 formation is given by

$$\frac{dn_{N_2}}{dt} = k_1 n_A = k_1 n_A^0 e^{-k_1 t} \qquad (1)$$

where n_A^0 is the initial number of azibenzyl moles.

By integration of (1) and with $n_A^0 = n_{N_2}^0$ ($n_{N_2}^0$ is the total number of N_2 moles at complete decomposition) equation (2) is obtained

$$k_1 = (2.303/t) \cdot \lg (n_{N_2}^0 / n_{N_2}^0 - n_{N_2}) \qquad (2)$$

Our experimental data follow this first order kinetics equation. As an illustration, in table 1 we give the number of N_2 moles and the rate constants for a working temperature of 50° and a $3 \cdot 10^{-2}$ mole/l azibenzyl concentration.

Table 1

The determination of rate constants with the 1st technique at $T = 50°$

				Average :	13.95

The values of the rate constants determined by the second chromatographic technique are given in table 3.

The rate constants from spectrophotometric measurements were calculated with equation (3)

$$k_1 = (2.303/t)\,.\,\lg(\varepsilon_0/\varepsilon_t) \tag{3}$$

where ε_0 and ε_t are the optical densities of the initial solution and after a reaction time t, respectively. These were measured at $\lambda = 320$ nm at which wavelength the azibenzyl has an absorption maximum and the reaction product is not absorbing.

Table 4

Spectrophotometric determination of rate constants at $T = 50°$

Time (min)	ε	$\lg \dfrac{\varepsilon_0}{\varepsilon_t}$	$k_1\cdot 10^4$ sec^{-1}
0	1.95	—	—
12	1.84	0.0253	0.808
30	1.64	0.0751	0.959

420	0.16	1.0859	0.991
495	0.1	1.29	0.99

Average : $k_1 = 0.974\cdot 10^{-4}$

As an illustration the rate constants for a temperature of 50° of a solution of $4\cdot 10^{-3}$ mole/l are given in table 4.

It was found that the rate constant satisfies quite well equation (3) and its mean values come close to that calculated from the determinations of N_2 by the chromatographic technique.

The values of the rate constants for a whole range of temperatures are given in table 5.

Table 5

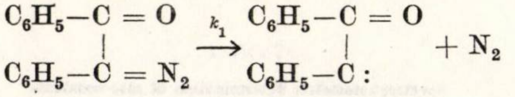
Kinetic parameters determined spectrophotometrically at several temperatures

T °C	$k_1 \cdot 10^4$ sec^{-1}	lg A
40	0.262	13.93
50	0.974	13.96
60	3.12	13.90
65	6.01	13.93
70	9.24	13.87

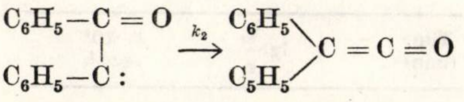
Average: 13.91

DISCUSSION

The first order kinetics verified by our experimental data both by relation to the N_2 evolved from the reaction and to the azibenzyl decomposed, suggests the following mechanism also mentioned in literature.[4,10]



$$\begin{array}{c} C_6H_5-C=O \\ | \\ C_6H_5-C=N_2 \end{array} \xrightarrow{k_1} \begin{array}{c} C_6H_5-C=O \\ | \\ C_6H_5-C: \end{array} + N_2 \qquad (4)$$



$$\begin{array}{c} C_6H_5-C=O \\ | \\ C_6H_5-C: \end{array} \xrightarrow{k_2} \begin{array}{c} C_6H_5 \\ C_5H_5 \end{array}\!\!\!>C=C=O \qquad (5)$$

The number of the N_2 moles measured at the end of the reaction corresponds quantitavely to the theoretical value according to the stoichiometry of reaction (4). This excludes the possibility of a secondary reaction between the intermediate radical and a molecule which is not decomposed, with the formation of the corresponding ketazene as it is reported in the thermal decomposition of diphenyldiazomethane.[15]

A reaction with the solvent is not likely to occur because the latter is inert.

The formation of diphenylketene could not be studied quantitatively by the spectrophotometric technique, as it presents an absorption maximum[16] at $\lambda = 409$ nm (the molar extinction coefficient $K = 270$) and the azibenzyl, having an absorption maximum at $\lambda = 435$ nm, absorbs well at $\lambda = 409$ nm ($K = 103$).

---

[15] T. Oncescu, M. Contineanu and G. Bălăceanu, *Rev. Roumaine Chim.*, **17**, 213 (1972)

[16] G. Lardy, *J. Chim. phys.*, **21**, 281 (1932).

But in this case in the absorption spectra of azibenzyl solutions for different reaction times shown in figure 3, a shifting of the absorption maximum from 435 nm to 409 nm can be noticed, accompanied by an increase of the absorption. This proves the formation of diphenylketene at the expense of azibenzyl.

Mention must be made of the fact that if the heating of the solution is continued, the absorption begins to decrease at a certain moment, which indicates that a transformation of diphenylketene takes place too.

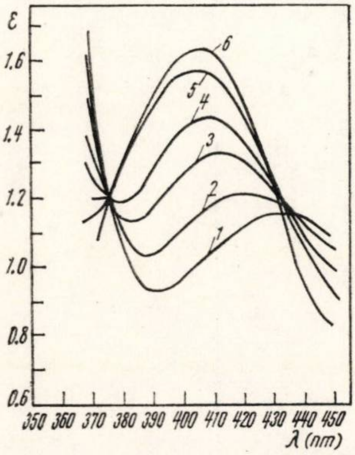


Fig. 3. — Absorption curves watching the diphenylketene formation at $T = 60°$ during the reaction.

1 – 6 various reaction moments between 0 – 60 minutes.

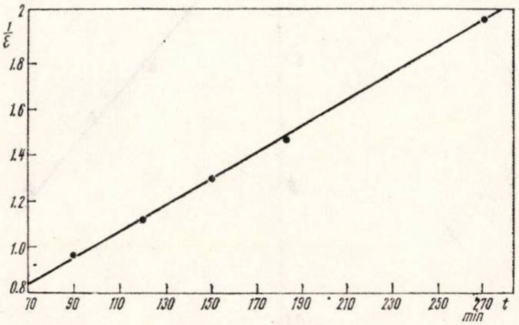

Fig. 4. — Plotting reciprocal values of diphenylketene absorption $\frac{1}{\varepsilon}$ *versus* time at $T = 60°$.

Plotting $1/\varepsilon$ measured at $\lambda = 409$ nm as function of time, a straight line is obtained, characteristic of the reaction :

$$2A \rightarrow B$$

suggesting the disappearance of diphenylketene from the system through dimerization.

It is known from literature that diphenylketene forms dimers, as can be also seen from our experimental data.

Figure 5 shows the values of log k versus $1/T$, obtained from the three techniques we used. From the slope of the straight line an activation energy of 26.5 Kcal/mole was calculated, whose value agrees quite well, with the values typical of unimolecular processes.

Using this energy the pre-exponential coefficients were calculated for all the working temperatures in the three techniques used, and they are given in tables 2, 3, 5. They agree each other leading to a mean value of log $A = 13.93$.

This points to a pre-exponential coefficient of about 10^{14} $\sec^{-1}$. With the aid of equation (6) the activation entropy $\Delta S^* = 3$ e.u. was calculated.[17]

$$A = \frac{e k T_m}{h} e^{\Delta S^*/R} \tag{6}$$

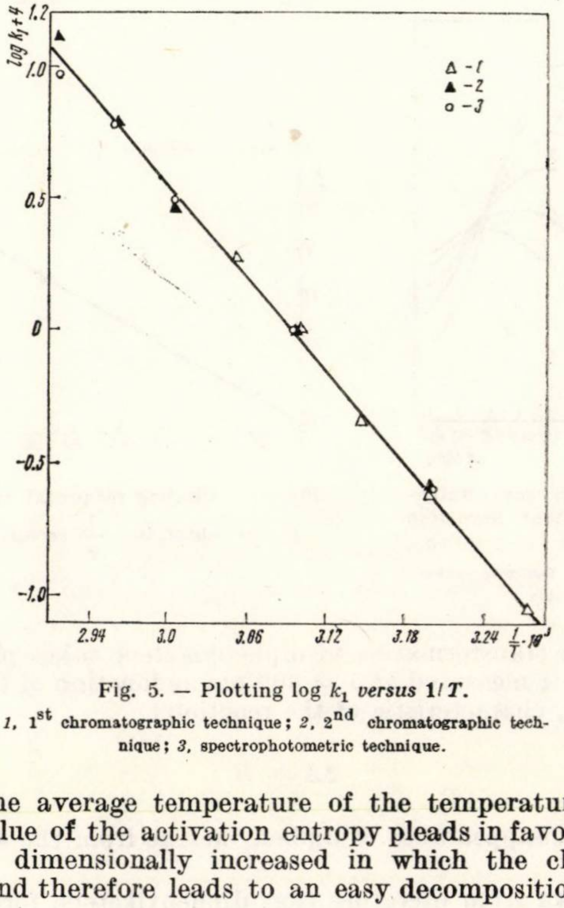

Fig. 5. — Plotting log k_1 *versus* 1/*T*.

1, 1st chromatographic technique; *2*, 2nd chromatographic technique; *3*, spectrophotometric technique.

where T_m is the average temperature of the temperature range used. The positive value of the activation entropy pleads in favour of an activated complex, dimensionally increased in which the chemical bonds are weakened and therefore leads to an easy decomposition of azibenzyl.

Researches on dilute liquid cadmium solutions in lead carried out by means of emf measurements of concentration cells : Cd | $CdCl_2$ in LiCl-KCl | Cd–Pb resulted in determination of thermodynamic properties in the form of Wagner equation : $\ln \gamma_{Cd} = \ln\gamma^0_{Cd} + X_{Cd}\,\varepsilon^{Cd}_{Cd}$. On the basis of the known thermodynamic data of liquid metal and salt phases the equilibrium constant of side reaction : $Pb + CdCl_2 = Cd + PbCl_2$ occurring in the concentration cell has been determined. Also the curve of equilibrium compositions was obtained and the range of compositions and temperature in application to Cd – Pb system has been considered.

In the investigations on dilute zinc solutions with $X_{Zn} = 0.01-0.1$ molar fraction in the systems Zn–Cd[1] and Zn–In,[2] using the emf method of the concentration cells, it has been found that the results for $X_{Zn} = 0.01$ show considerable errors. They are caused by the side reactions which occur between $ZnCl_2$ from the electrolyte and the components of alloy electrode, especially when they are placed near the zinc in the electromotive series.

Hence we may conclude that the occurring of side reactions may be combined with the difference in standard free energy of the formation of chlorides appearing in electrolyte and of the alloy component. Wagner [3] informs that if the absolute value of the difference $\Delta F^0_{ZnCl_2} - \Delta F^0_{MCl_2}$ (where M = the alloy component) is greater than 7000 cal then the side reaction does not take place at all or its effect is negligible.

As a result of side reactions for the molar fraction $X_{Zn} = 0.01$, especially at higher temperatures, the amount of alloy component is being reduced and thus the increase of the electromotive force with temperature is smaller, which as a consequence leads to higher values of the activity coefficients. This is evident from Fig. 1 in which the results of the investigations on the dilute Zn—Pb[4] Zn—Cd[1] and Zn—In[2] and Cd—Pb solutions described in the present paper, are enclosed. As

In paper[5] the side reaction is discussed which occurs in the investigations of zinc-cadmium dilute solutions

$$ZnCl_2 + Cd = Zn + CdCl_2 \tag{1}$$

and the equilibrium constant of this reaction has been determined on the basis of the thermodynamic properties of the dilute Zn–Cd, $ZnCl_2$ and $CdCl_2$ solutions in the eutectic LiCl–KCl.

The present paper discusses the side reaction

$$Pb + CdCl_2 = Cd + PbCl_2 \tag{2}$$

which occurs in the investigations on the dilute solutions of cadmium in lead when applying the method of the electromotive forces of concentration cells as a result of the similar electrochemical properties of cadmium and lead. For this purpose the thermodynamic properties of the dilute Cd–Pb solutions have been determined, which in connection with the previously carried out investigations on the activity of $CdCl_2$[5] and $PbCl_2$[6] in the eutectic LiCl–KCl will help to define the equilibrium constant of the reaction (2) and relate it to the alloy composition and temperature above which this reaction takes place.

THERMODYNAMIC PROPERTIES OF THE DILUTE Cd–Pb SOLUTIONS

Applying the emf method of the concentration cells with liquid electrodes and liquid electrolyte the cells have been arranged according to the following scheme :

$$Cd \mid CdCl_2 \text{ in the eutectic } LiCl - KCl \mid Cd{-}Pb \tag{3}$$

The way of preparing the electrolyte and its dehydration have been described in one of the previous papers.[1,2,4] The purity of the metals used for preparing the alloys was not less than 99.99%. The measurements were made at temperatures from 680–840 K in the concentration range of cadmium $X_{Cd} = 0.01-0.1$ molar fraction. The obtained values of the electromotive forces depending on temperature are shown in Fig. 2. Using the least squares method their mean values have been found, and from the obtained linear equations the values of the electromotive forces at the temperatures : 714, 757, 805, 842 and 877 K have been determined, and these again were used for further calculations. In

[6] L. Yang and R. Hudson, *Trans. of AIME*, **215**, 589 (1959).

Table 1 are given the linear equations from which the E_{mV} values for the temperatures 714–877 K were calculated, and these were next used to obtain the values of the activity coefficient for cadmium from the dependence

$$\gamma_{Cd} = \frac{1}{X_{Cd}} e^{\frac{-nEF}{RT}} \tag{4}$$

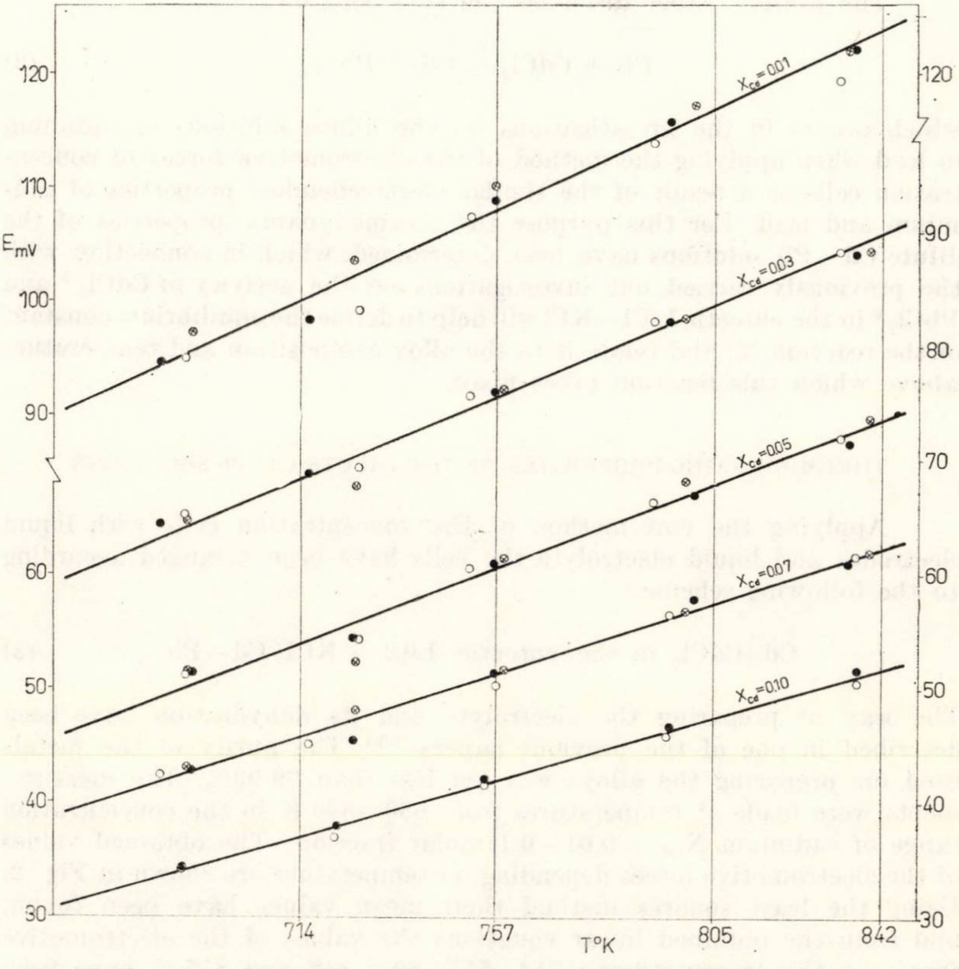

Fig. 2. – Dependence of E_{mV} on temperature in liquid dilute Cd–Pb solutions.

where γ_{Cd} – activity coefficient of cadmium,
X_{Cd} – concentration of cadmium in molar fractions,
n – valence, ($n = 2$),
E – electromotive force,
F – Faraday's constant (23066 cal/volt).

On the basis of the obtained results, a diagram (Fig. 1) showing the dependence of ln γ_{Cd} *vs* X_{Cd} for the temperature range 714–877 K has been plotted. As can be seen from Fig. 1 due to the side reaction (2) higher values of ln γ_{Cd} for $X_{Cd} = 0.01$ are obtained when compared with the results given for the other concentrations, especially at higher temperatures. From the above diagram it is possible to determine the interaction parameters derived by Wagner[7] using the least squares method from the dependence

Table 1

Experimental results in dilute Cd–Pb solutions

X_{Cd}	Linear equations obtained by the least squares method	$\ln\gamma_{Cd}$					$T°K$	$\ln \overset{\circ}{\gamma}_{Cd}$	ε_{Cd}^{Cd}
		714°	757°	805°	842°	877°			
0.01	$E = -32.405 + 0.18544\ T$	1.348	1.236	1.132	1.060	0.998	714	1.376	−2.79
0.03	$E = -52.372 + 0.16900\ T$	1.292	1.187	1.088	1.020	0.960	757	1.261	−2.45
0.05	$E = -55.875 + 0.15375\ T$	1.236	1.138	1.044	0.979	0.922	805	1.155	−2.21
0.07	$E = -46.226 + 0.12882\ T$	1.181	1.090	1.000	0.938	0.884	842	1.081	−2.04
0.10	$E = -45.376 + 0.11531\ T$	1.097	1.016	0.934	0.877	0.827	877	1.017	−1.90

$$\varepsilon_{Cd}^{Cd} = \left(\frac{\partial \ln \gamma_{Cd}}{\partial X_{Cd}}\right)_{X_{Cd}=0} \tag{5}$$

To establish the slope for the temperature 714° the values of ln γ_{Cd} were taken for all concentrations, whereas for all the other temperatures only the values starting from $X_{Cd} = 0.03$. The values ε_{Cd}^{Cd} given in Table 1 were used to establish the dependence of ε_{Cd}^{Cd} on temperature. For this purpose the Fig. 3, ε_{Cd}^{Cd} *vs* $\frac{1}{T}\ 10^3$ was plotted, from which the following relation was derived

$$\varepsilon_{Cd}^{Cd} = -\frac{3273}{T} + 1.827 \tag{6}$$

In a similar way from the limiting values of the activity coefficients $\ln \gamma_{Cd}^{0}$ in Table 1 the dependence on temperature has been established and the following formula obtained

$$\ln \gamma_{Cd}^{0} = \frac{1385}{T} - 0.504 \tag{7}$$

Making use of formulae (6) and (7) it is possible to establish, in accordance with Wagner,[7] relation for the activity coefficient of cadmium in the dilute liquid solutions in lead as a function of the composition of the solution

---

[7] C. Wagner, "Thermodynamic of alloys", Cambridge Massachusets, 1952.

$$\ln \gamma_{Cd} = \ln \gamma^0_{Cd} + X_{Cd}\, \varepsilon^{Cd}_{Cd} \tag{8}$$

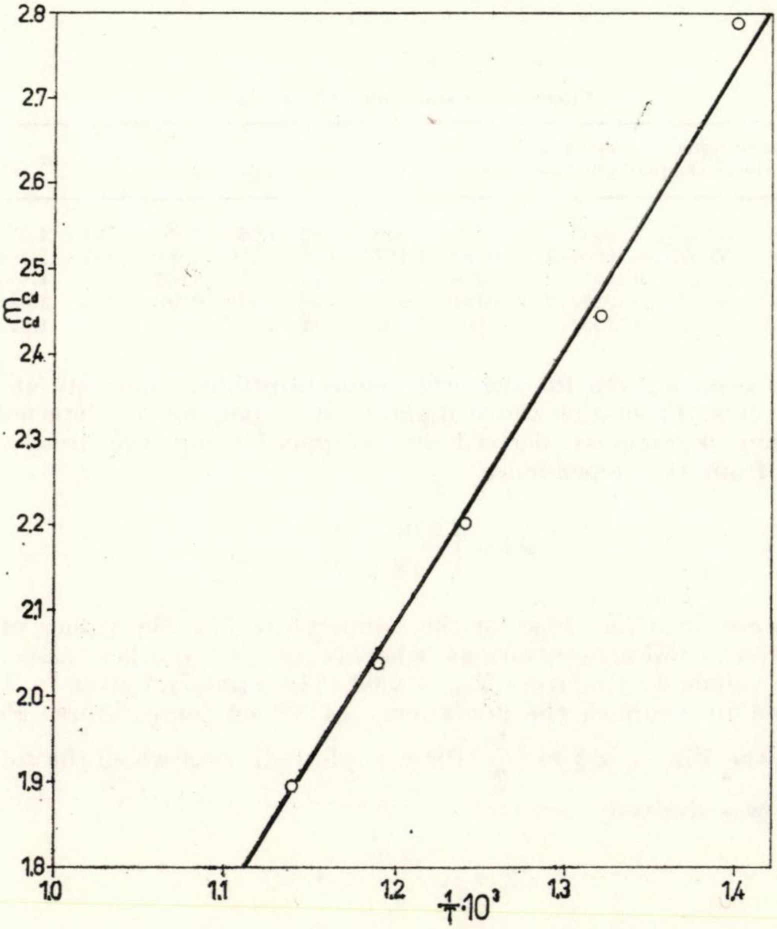

Fig. 3. — Dependence of self-interaction parameter ε^{Cd}_{Cd} *vs* $\frac{1}{T} \cdot 10^3$ in liquid dilute Cd—Pb solutions.

Formula (8) may be successfully applied for the concentration range $X_{Cd} = 0.01-0.1$ molar fraction. To calculate the equilibrium constant of the side reaction (2) the data obtained from Eq. (7) are used.

THE EQUILIBRIUM CONSTANT OF REACTION (2) IN THE CONCENTRATION CELL

The reaction occurring between the lead of the alloy electrode and the cadmium chloride in the salts may be considered from the point of view of the equilibrium between the salt and the metal phase. Considering the fact that both cadmium in lead in the metal phase as well as $CdCl_2$ and $PbCl_2$ in the solution with LiCl–KCl in the salt phase are dilute solutions, the equilibrium constant of reaction (2) may be presented as follows

$$K = \left(\frac{1 - X_{CdCl_2}}{X_{CdCl_2}}\right)\cdot\left(\frac{X_{Cd}}{1 - X_{Cd}}\right)\cdot\frac{\gamma^0_{PbCl_2}}{\gamma^0_{CdCl_2}}\cdot\gamma^0_{Cd} \tag{9}$$

assuming that $X_{CdCl_2} + X_{PbCl_2} \cong 1$; $X_{Cd} + X_{Pb} \cong 1$ and $\gamma_{Pb} \cong 1$. In Eq. (9):

γ^0_{Cd} – limiting activity coefficient of cadmium in lead when $X_{Cd} = 0$,

$\gamma^0_{CdCl_2}$ – limiting activity coefficient of $CdCl_2$ in LiCl – KCl when $X_{CdCl_2} = 0$,

$\gamma^0_{PbCl_2}$ – limiting activity coefficient of $PbCl_2$ in LiCl – KCl when $X_{PbCl_2} = 0$.

When assuming Eq. (9) at the assumption that the metal and the salt phases behave like ideal solutions, the following dependence has been obtained

$$X_{CdCl_2} = \frac{1}{(1 - K) + \dfrac{K}{X_{Cd}}} \tag{10}$$

whereas in the case of real solutions

$$X_{CdCl_2} = \frac{1}{(1 - K') + \dfrac{K'}{X_{Cd}}} \tag{11}$$

$$\text{where}: K' = \left(\frac{K}{\gamma^0_{Cd}}\right)\cdot\left(\frac{\gamma^0_{CdCl_2}}{\gamma^0_{PbCl_2}}\right) \tag{12}$$

what makes possible the calculation of the equilibrium compositions of reaction (2). It follows from Eqs. (10) and (12) that for this purpose it is necessary to know:

1. the equilibrium constant K of reaction (2) which can be calculated from the free energy change ΔF^0_T of the reaction (2),

2. the value γ^0_{Cd}, which can be defined from the thermodynamic properties of the dilute Cd–Pb solutions,

3. the values $\gamma^0_{CdCl_2}$ and $\gamma^0_{PbCl_2}$, which can be defined from the thermodynamic properties of the dilute $CdCl_2$–LiCl–KCl and $PbCl_2$–LiCl–KCl solutions.

THE DETERMINATION OF THE EQUILIBRIUM CONSTANT K

In the previous paper[5] a formula has been derived for the mean value of $E^0_{CdCl_2} = 1.6990 - 0.000599\ T°$. (13)

On the basis of the works by Lorenz and Velde[8], Lantratow andAłabyszew,[9] Wachter and Hildebrandt[10] the mean value of $E^0_{PbCl_2}$ has been established

$$E^0_{PbCl_2} = 1.5766 - 0.000602\ T° \tag{14}$$

The change in the standard free energy ΔF^0_T of reaction (2) can be calculated from the Eq.

$$\Delta F^0_T = -2F(E^0_{PbCl_2} - E^0_{CdCl_2}) \tag{15}$$

which in connection with the known dependence

$$\Delta F^0_T = -RT \ln K$$

allowed to determine the value K of reaction (2) at the temperatures 773, 823 and 873 K.

THE DETERMINATION OF THE $\gamma^0_{PbCl_2}$ and $\gamma^0_{CdCl_2}$ VALUES

In paper,[5] $\gamma^0_{CdCl_2}$ values have been defined by constructing the cells of formation of $CdCl_2$ with chlorine electrode. The activity measurements of $CdCl_2$ carried out in the range of dilute solutions ($X_{CdCl_2} = 0.010 - 0.073$) in the eutectic LiCl—KCl allowed the extrapolation of the values $\ln \gamma_{CdCl_2}$ to $\ln \gamma^0_{CdCl_2}$ when $X_{CdCl_2} = 0$. This was possible due to the linear dependence of $\ln \gamma_{CdCl_2}$ *vs* X_{CdCl_2} obtained for the dilute $CdCl_2$ solutions. Similarly $\gamma^0_{PbCl_2}$ has been defined basing on the work of Yang and Hudson[6] by extrapolating the obtained values of electromotive forces of the cell Pb | $PbCl_2$—LiCl—KCl | Cl_2 to the temperatures 773, 823, 873 K; and next from plots $\ln \gamma_{PbCl_2}$ *vs.* X_{PbCl_2} the dependence of $\ln \gamma^0_{PbCl_2}$ on temperature has been defined by the Eq.

$$\ln \gamma^0_{PbCl_2} = -\frac{175}{T} - 0.655 \tag{16}$$

from which the values of $\gamma^0_{PbCl_2}$ (when $X_{PbCl_2} = 0$) have been obtained.

The corresponding values of γ^0_{Cd} have been calculated from (7). The obtained values are given in Table 2.

Table 2

The values of equilibrium constant of side reaction (2) and the terms in Eq. (9)

$T° K$	ΔF°_T	K	$\overset{\circ}{\gamma}_{Cd}$	$\overset{\circ}{\gamma}_{CdCl_2} \cdot 10^2$	$\overset{\circ}{\gamma}_{PbCl_2} \cdot 10^2$	K'
773	5716	0.024	3.41	4.54	41.41	0.00078
823	5720	0.030	2.06	5.59	41.98	0.00130
873	5730	0.037	2.78	6.73	42.50	0.00209

Basing on the data given in Table 2 and Eqs. (10), (11) the equilibrium compositions of reaction (2) have been determined and compared with the experimental data obtained by Lorenz, Frenkel and Silberstein [11] and by Jellinek and Hewsky [12]. The comparison is shown in Fig. 4.

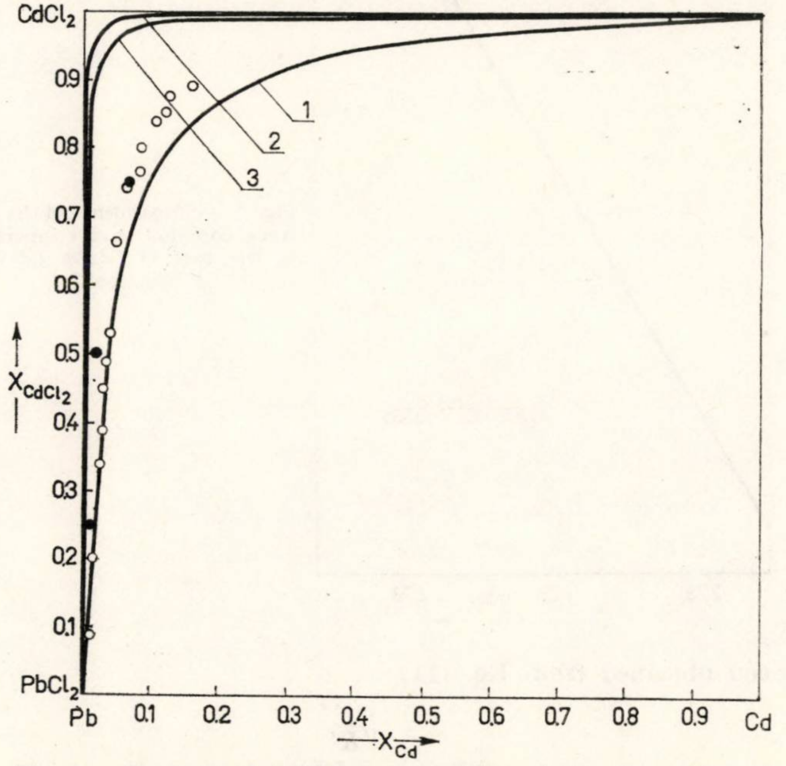

Fig. 4. — The curve of equilibrium compositions of the side reaction (2) in comparison with ideal solutions and the data obtained from literature.

1, correspond to ideal solutions at temperature 873 K; *2*, *3*, correspond to real solutions calculated respectively at temperatures 773 K (line 2) and 873 K (line 3);

○ — data of Lorenz, Frenkel and Silberstein [11] at 873 K,

● — data of Jellinek and Hewsky [12] at 873 K.

---

[11] R. Lorenz, W. Frenkel and F. Silberstein, *Z. anorg. Chem.*, **131**, 247 (1923).

[12] K. Jellinek and D. Hewsky, *Z. Elektrochem.*, **39**, 444 (1933).

Assuming that the beginning of the side reaction in the cell corresponds to a point on the equilibrium curve when

$$\frac{dX_{CdCl_2}}{dX_{Cd}} = 1 \tag{17}$$

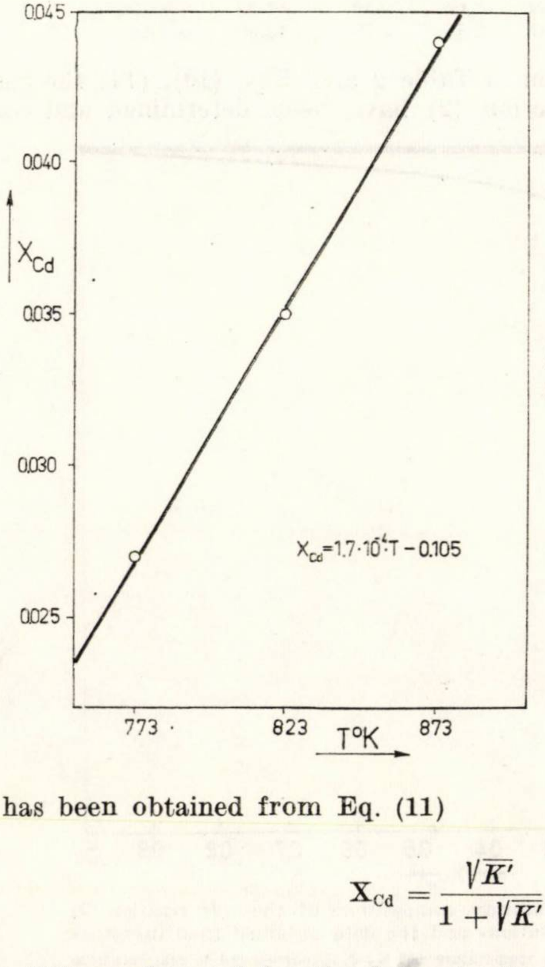

Fig. 5. — Dependence of the electrode composition on temperature in the case of liquid Cd — Pb solutions.

it has been obtained from Eq. (11)

$$X_{Cd} = \frac{\sqrt{K'}}{1+\sqrt{K'}} \tag{18}$$

Eq. (18) can be used for the determination of the composition of alloy electrode depending on temperature. The obtained results are defined by the formula

$$X_{Cd} = 1.7\cdot10^{-4}\cdot T - 0.105 \tag{19}$$

which is plotted in Fig. 5. It is easy to calculate that the composition $X_{Cd} = 0.01$ is attained by the electrode already at 677 K and $X_{Cd} = 0.03$ at 793 K. Fig. 1 confirms the deviation of the points caused by reaction (2) at 757 K for $X_{Cd} = 0.01$ and for $X_{Cd} = 0.03$ at 805 K.

DISCUSSION AND CONCLUSIONS

In the present paper the equilibrium constant of a side reaction occurring in the concentration cell when investigating liquid solutions of cadmium in lead has been defined. It has been found that the condition 7000 cal given by Wagner and the difference between the standard free energy of forming of the respective chlorides is confirmed not only when zinc forms the reference electrode and $ZnCl_2$ is present in electrolyte, but also when investigations deals with cadmium in lead solutions.

A detailed discussion on the subject of applying the metal-salt equilibrium dependences for defining the equilibrium of the side reaction in the cell is to be found in.[5] In reference to the $Cd-Pb-CdCl_2-PbCl_2$ system the identical phenomenon of divergence between the experimental data [11,12] and the curve calculated from (11) is observed. This phenomenon is caused by the presence of the eutectic LiCl$-$KCl when defining the experimental values of $\gamma^0_{CdCl_2}$ and $\gamma^0_{PbCl_2}$. Similarly as in [5] the eutectic is not a neutral medium when the thermodynamic properties of $CdCl_2$ and $PbCl_2$ in the $CdCl_2-LiCl_2-KCl$ and $PbCl_2-LiCl-KCl$ solutions are being determined.

The observed discrepancy between the calculated temperatures at the beginning of the side reaction and the corresponding temperatures resulting from Fig. 2 for the assumed compositions: $X_{Cd} = 0.01$ and $X_{Cd} = 0.03$ is due to the combination of the investigation results carried out independently on the Cd$-$Pb system in the concentration range $X_{Cd} = 0.1-0.9$ and $X_{Cd} = 0.01-0.07$.

When the points for $X_{Cd} = 0.1$ are disregarded and the results obtained only for low concentrations taken into account the agreement is considerably better. This may have some connection with the fact that, in practice, $PbCl_2$ is always formed, though not any amount of it distorts the e.m.f. measurements. Therefore, as the composition of the beginning of the side reaction there should be considered such amount of $PbCl_2$ in the solution which would distort the e.m.f. measurement. For the composition $X_{Cd} = 0.1$ in the solution there is some amount of $PbCl_2$ (Fig. 1), which unavoidably affects the measurement result but does not distort it i.e. reaction (2) does not occur yet. It causes probably the shifting of the points for $X_{Cd} = 0.1$ (Fig. 1) in relation to the points obtained in the concentration range $X_{Cd} = 0.01-0.07$ when the $PbCl_2$ content is increasing. This remark suggests that the formula defining the thermodynamic properties of metal solutions based on the data obtained by the e.m.f. method should be determined on the basis of experimental data from the concentration range $X_{Cd} = 0.9-0.5$, where the amount of the formed $PbCl_2$ is possibly small.

Получена 26 сентября 1972

Предметом настоящей работы является исследование фазового состава катализатора, к которому с целью улучшения термических свойств добавлены марганец и алюминий. Образцы одинакового основного состава подвергнуты рентгеноструктурному анализу при комнатной температуре и при повышенных температурах, в атмосфере водорода, окиси углерода или их смеси. Полученные результаты показывают, что улучшение активности и термической устойчивости катализатора с добавкой марганца можно объяснить полным восстановлением окиси меди до элементарной меди с повышенной кристалличностью присутствием закиси меди в большом количестве. Присутствие алюминия, который проявляет ингибирующее действие на активность катализаторов, препятствует образованию кристаллических структур основных компонентов, а также восстановлению окиси меди до элементарной меди и закиси меди.

В нашей предыдущей работе [1] показаны результаты рентгенофазового анализа катализатора для низкотемпературной конверсии окиси углерода, синтетизированного в нашей лаборатории, основные компоненты которых показаны последовательно по количественному присутствию: цинк-медь-хром. В отсутствии добавок, при температуре 180—250°, этот катализатор способствует конверсии окиси углерода в выходном газе до 0,2%, но при температурах больше 250° он теряет свою каталитическую активность. Рентгеноструктурным анализом в атмосфере воздуха при комнатной температуре и высокотемпературной рентгеновой дифракцией в атмосфере водорода, окиси углерода и воздуха, мы установили, что образцы этого катализатора, которые отличаются высокой активностью, характеризуются выделением элементарной меди при относительно низких температурах, присутствием закиси меди в измерительных количествах и хорошим формированием кристаллической решетки окиси цинка. После прокалки при температурах свыше 500° в катализаторе этого состава замечено появление цинкохромового шпинеля.

Задачей этой работы является определение фазового состава катализатора, к которому, с целью улучшения термических свойств, добавляли марганец и алюминий. Наши предыдущие исследования влияния большого числа добавок [2] показали, что окиси этих двух металлов, добавленые одновременным осаждением с основными компонентами, приводят к значительному изменению активности катализатора. Присутствие марганца улучшает каталитическую активность и термическую устойчивость катализатора, в тоже время алюминий проявляет заметное тормозящее действие.

Для утверждения способа действия этих добавок интересным является результат, полученный методом термического анализа [3], где в интервалах температур, при которых каталитическая активность изменялась, происходили фазовые трансформации, зарегистрированные в образцах с добавками и без добавок.

В этой работе использовался метод рентгеноструктурного анализа при комнатной температуре в атмосфере воздуха и рентгеновская дифракция при повышенной температуре в атмосферах водорода и окиси углерода, а также и в их смеси, образцов того же основного состава, к которым добавлены марганец или алюминий в количестве до 0,2%.

Результаты исследования фазового состава при комнатной температуре, до и после активирования образцов с добавками, показаны на рисунках 1 и 2.

На рисунке 1 представлена рентгенограмма образца катализатора с добавкой марганца, который отличается высокой активностью, до 0,2% окиси углерода в выходном газе и хорошей термической устойчивостью до 400°. На рисунке видны пики окислов металлов, представленных в образце до исследования его активности (1) и после исследования активности, [2] при условиях составе газовой смеси, объемной скорости и температуре, которые способствуют промышленному применению. На рисунке 2 показана рентгенограмма образца с добавкой алюминия, который характеризуется значительно меньшей активностью, до 5,2% окиси углерода в выходном газе. И в этом случае рентгенограммы получены при 20° в атмосфере воздуха до [1] и после [2] исследования активности, проведенного в тех же самых условиях, как и в случае исследования катализатора без добавок и с добавками марганца.

Сопоставление рентгенограммы образцов с добавками между собой и с результатами, полученными исследованием без добавок [1], можно отметить полную аналогию разниц в активности и в фазовом составе. Образец с добавкой марганца [1] характеризуется до исследования активности присутствием окиси цинка и окиси меди в кристаллическом виде, а окись хрома находится в аморфном состоянии. После активирования [2] в этом образце, наряду с хорошо формированной решеткой окиси цинка, появляются и четкие дифракционные линии элементарной меди и очень нечеткие и «размытие» линии окиси меди. Эта рентгенограмма отличается от рентгенограммы образца без добавок [1], отсутствием измерительных количеств окиси меди, что указывает на ускорение превращения этой фазы в присутствии добавленного марганца.

[3] P. Putanov, Ž. Jovanović i Bj. Aleksić, *Bull. soc. chem. Beograd*, **35**, 285 (1970).

Катализатор с добавкой алюминия, показан на рисунке 2, имеет до и после активирования фазового состава подобен менее активному катализатору без добавок [1]. До восстановления в этом образце плохо сформирована кристаллическая решетка окиси цинка и окиси меди, а окись хрома в аморфном состоянии; после восстановления появляются очень небольшие количества закиси меди.

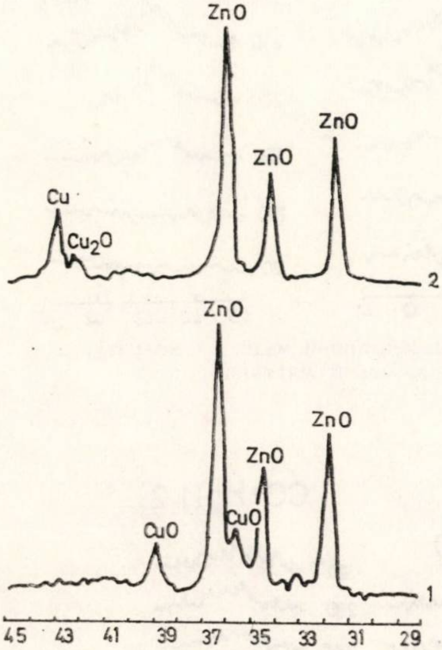

Рис. 1. — Характерные пики рентгенограммы катализатора с добавкой марганца до (1) и после (2) исследования активности.

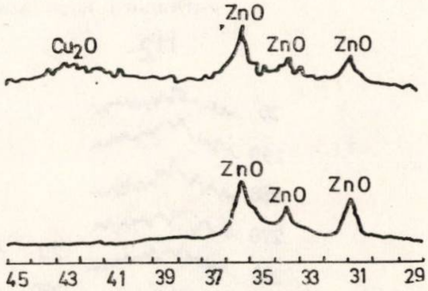

Рис. 2. — Характерные пики рентгенограммы катализатора с добавкой алюминия до (1) и после (2) исследования активности.

Следовательно, улучшение активности и термической устойчивости, которое выражает катализатор с добавкой марганца, можно объяснить выделением элементарной меди с большой степенью кристалличности, присутствием закиси меди в больших количествах и полным восстановлением окиси меди. В присутствии алюминия заметно ограничено формирование кристаллической структуры основных компонентов: окиси цинка и окиси хрома, а также восстановление окиси меди в элементарную медь и закись меди.

Ни у одного из двух образцов с добавками не замечено появление шпинельной структуры в интервале до 400°, марганец и алюминий не могли быть обнаружены, имея в виду чувствительность метода при количествах 2%.

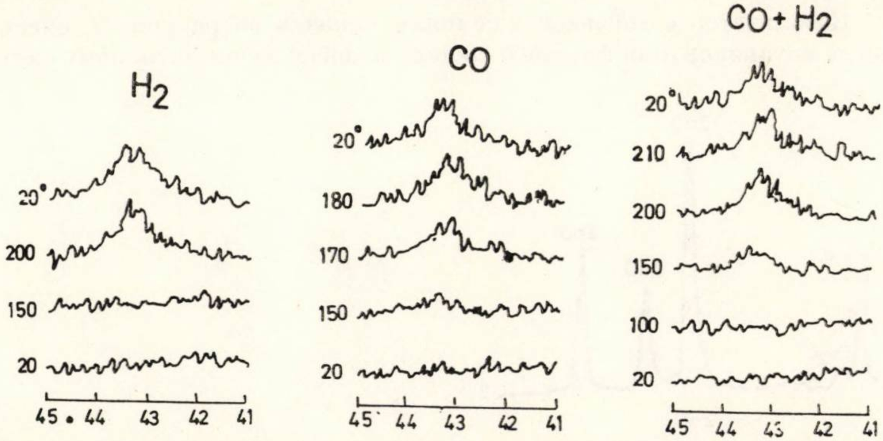

Рис. 3. — Характерные пики появления элементарной меди с температурой у активного катализатора с добавкой марганца.

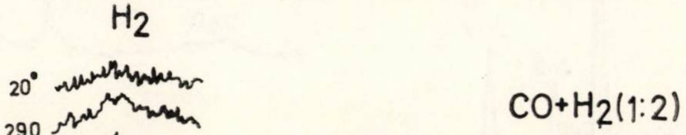

Рис. 4. — Характерные пики появления элементарной меди с температурой у менее активного катализатора с добавкой алюминия.

Результаты исследований влияния температуры на выделение элементарной меди в различных восстановительных средах показаны на рисунках 3 и 4.

На рисунке 3 показаны пики элементарной меди, замеченные с помощью высокотемпературной рентгеновой камеры при исследовании образца с добавкой марганца в атмосферах водорода, окиси углерода и в смеси этих двух газов в соотношении 1 : 1.

Как видно на рисунке, элементарная медь появляется уже при температуре около 170°, независимо от газовой среды. При 200° количество формированной меди значительно, оно потом замечается и на охлажденном катализаторе (20°).

На рисунке 4 показаны аналогические результаты, полученные для образца с добавкой алюминия. У этого катализатора образование меди начинается только при температуре 200°; замечается, что линии очень слабые и размытые. При более высоких температурах (300—400°) во всех образцах замечено появление закиси меди.

Улучшение качеств катализатора с добавкой марганца, которые отражаются как на активность, так и на термическую устойчивость этого образца, можно объяснить влиянием марганца на формирование кристаллической структуры компонентов и полным восстановлением окиси меди в элементарную медь. В тоже время можно сделать вывод, что алюминий в синтетизированном катализаторе препятствует формированию кристаллической структуры основных компонентов, а также формированию активного компонента — элементарной меди, в чем и выражается его ингибирующее действие.

На основании этих фазовых исследований можно заключить, что при синтезе катализаторов для низкотемпературной конверсии окиси углерода водяным паром состава цинк-медь-хром, необходимо добавлять марганец, совместным осаждением с основными компонентами, в качестве промотора.

INVESTIGATION OF SOME PROPERTIES OF THE AMMONIA SYNTHESIS CATALYSTS OBTAINED BY MELTING NATURAL MAGNETITE

BOJANA D. ALEKSIĆ and ANA TERLECKI-BARIČEVIĆ

Institute for Chemistry, Technology and Metallurgy,
Department for Catalysis, Beograd, Yugoslavia

Received September 26, 1972

Within the framework of systematic studying of ammonia synthesis catalyst properties and functions, investigations of correlations between the promotor addition procedure and physico-chemical properties and activity of catalysts obtained by fusion natural magnetite have been conducted. In addition to the determination of structural and textural characteristics of catalysts, measurements of electrical conductivity of unreduced catalysts, to which the same promotors have been added by two different procedures, were performed. Simultaneously, an industrial catalyst of similar type and a natural magnetite without promotors have been investigated. The results obtained have shown that the manner of addition the promotor affects to a large extent the investigated properties and catalyst activity in the reaction of ammonia synthesis.

Under the conditions of ammonia catalyst synthesis by high temperature melting, distribution of promotors in catalysts as well as their phase compositions depend, *inter alia*, on the procedure of promotors addition-sequence of addition, the nature of added promotor compound and relative concentrations of some of promotors.

Within the framework of ammonia synthesis catalyst properties and functions, investigations of correlations between promotor addition procedure and physico-chemical properties and activity of catalysts obtained by melting natural magnetite have been conducted.

EXPERIMENTAL

Natural magnetite from Yugoslav deposits of the "Ibarski rudnici" mine was purified by successive dry and wet separations.

Catalyst samples were synthetized by melting purified natural magnetite in electric-arc vacuum furnace with a wolfram electrode, in argon. [1] After melting the samples were cooled fast.

---

[1] B. D. ALEKSIĆ and Dj. I. MILOSAVLJEVIĆ, "Proceedings of the Ist National Congress on Chemical Engineering", June 1971, Beograd, Yugoslavia, p. 291.

Two different procedures of promotor addition were applied. Following the first, a mixture of magnetite and magnesium oxide powders has been soaked in aluminium nitrate solution, and ammonia hydroxide was added by dropping and permanent mixing; after washing and filtration, the slurry was mixed with lime, dried at 140° and soaked with alcoholic solution of potassium hydroxide; after elimination of alcohol by evaporation in vacuum, the sample was heated for 4 hours at 600° in air, and then subjected to melting. This sample was marked as MB—1.

By the second procedure, promotors under the form of aluminium, calcium and magnesium oxides and potassium carbonate, *p.a.* grade, were added to the powdered magnetite, and before melting, the mixture was homogenized in the rotated mixer for twelve hours. The sample was marked with MB—2.

Sample microstructure was investigated by metallographic microscope. Samples were ground with grinding papers and polished on the cloth with γ-alumina.

Specific surfaces determinations were performed by means of Perkin Elmer Shell, model 212 D, sorptometer.

The pore distribution was determined by the method of mercury porosimetry.

An attempt was made to investigate the distribution of promotors in a catalyst grain, by electron microprobe. Measurements were performed on the device type SEM—2, AEI—Manchester *. Radiations of potassium are detected only.

The electric conductivity changes of the synthetized samples were observed in vacuum, in nitrogen and in air in a temperature range of 100 to 450°. The measurement cycle in different atmosphere was identical for all synthetized samples and it consisted of heating the tablets in vacuum up to 450°, keeping at this temperature until constant resistance had been reached and then cooling with permanent evacuation. This cycle was repeated twice, the resistance being registered at every 50°, then a steam of nitrogen was passed over the tablet cooled to the room temperature and the resistance recorded during heating and cooling. The tablet was then evacuated for 30 minutes and conductivity measured during heating and cooling in air. In all cases the tablet was kept for about 30 minutes at 450° for resistance stabilization.

Within the framework of investigation of changes occurring during melting in natural magnetite as the catalyst base, the electric conductivity of natural magnetite without promotors was measured before and after melting. After outgasing the sample surface and stabilizing its electric conductivity in vacuum, the resistances were measured on heating and cooling in air, the cycle being repeated.

Measurement of catalytic activity, in reaction of ammonia synthesis were performed in the differential reactor at pressure of 280 at, the space velocities of the stoichiometric mixture of hydrogen, nitrogen and 5 % of inert gas being 10, 25 and 50.000 h^{-1} and temperatures up to 550°. Reduction was made *in situ*, with space velocities 25.000 h^{-1}. Granulation of the samples was of 4 — 6 mm, volume of catalyst bed 30 ml **.

RESULTS AND DISCUSSION

In Table 1, chemical compositions of natural magnetite, two synthetized samples and one commercial sample of industrial catalyst used for comparison, are listed.

---

* Measurements were performed at the Institute of Nuclear Sciences, Vinča, Beograd.

** Authors wish to express their thanks to ing. L. Sokol for the catalyst activity measurements in the laboratory of Chemical Works, Zaluži u Mostu, ČSSR.

For its rich content of magnetite fraction the selected magnetite was very convenient as a base for ammonia synthesis catalyst. Sulphur and phosphor being eliminated by evaporation during the melting process, the remaining ingredients in magnetite are in tolerant limits regarding their influence on catalyst activity.[2] The only disadvantage is a somewhat higher content of silica.

Table 1

Chemical composition of natural magnetite and investigated catalyst samples

Component sample	Natural magnetite	MB – 1	MB – 2	Industrial catalyst (D)
Magnetite fraction	96.59	—	—	—
Fe — total	69.40	61.40	63.72	67.89
Fe^{+2}	23.13	24.44	32.21	27.64
Fe^{+2}/Fe^{+3}	0.50	0.66	1.02	0.40
SiO_2	2.54	3.00	2.70	1.30
Al_2O_3	0.20	4.10	3.50	1.82
CaO	none	1.39	1.75	1.36
MgO	0.65	0.81	1.15	0.77
K_2O	—	0.75	1.54	0.32
S	0.60	none	none	none
P_2O_5	0.04	none	none	none
MnO	0.03	—	—	—
Na_2O+K_2O	0.12	—	—	—

According to the chemical analysis results, the conclusion might be drawn that less potassium evaporation from the surface occurred with the melted sample that contained potassium carbonate than with that one in which potassium hydroxide solution was poured.

The different way of promotors deposition on the catalyst surface may have protective effects on the shift of iron oxidation state during melting in an inert atmosphere, which resulted in the difference of Fe^{+2}/Fe^{+3} ratio in the MB-1 and MB-2 samples.

Microstructure of the natural magnetite, melted without promotors and two synthetized catalyst samples, is shown in Fig. 1 (a—c).

Presence of promotors in the MB-1 and MB-2 samples resulted, *inter alia*, in occurrence of finer, more developed dendrites and smaller pores.

Specific surfaces were of order 10^{-1} m²/g for natural magnetite and unreduced samples MB-1 and MB-2, sample granulation being $-1.02 + + 2$ mm, but the results obtained prevented drawing a definite conclusion concerning the dependence of the specific surface on the mode of catalyst synthesis.

---

[2] J. Beneš and J. Šuša *Chem. průmysl.*, 10/35, **9**, 453 (1960).

The cumulative pore volume against pore radius in synthetized samples is shown in Fig. 2. Besides the evident difference in cumulative pore volumes, the size of pores and shape of their relative distribution curves are similar for both samples.

Table 2

Activation energies of electrical conductivity for samples obtained by melting magnetite

Sample	E, eV		
	Vacuum	Nitrogen	Air
MB−1	0.32(100−350°) 0.42(350−450°)	0.25(100−350°) 0.52(350−450°)	0.38(100−200°) 0.68(200−450°)
MB−2	0.29(150−250°) 0.80(250−450°)	0.48(150−300°) 1.22(300−450°)	0.67(150−280°) 1.44(280−450°)
D	0.42(215−300°) 1.10(300−425°)	0.57(215−350°) 1.24(350−425°)	0.41(125−260°) 1.54(260−425°)
Melted magnetite	0.60(200−450°)	0.95(250−450°)	0.61(150−300°) 0.85(300−450°)

Higher porosity of MB-2 sample may be the result of a more effective porous structure regulation during the cooling process in the presence of promotors in the form of powdered oxides.

Distribution of promotors in catalyst grain investigated by electron microprobe is shown in Figs. 3 and 4 (a−b).

On the electronic picture of the chosen part of MB-2 sample surface, shown in Fig. 3, bright surfaces are visible surrounded by dark ones, like a network; inside the bright areas there are dark points corresponding to various concentrations of the promotor in the holes or grain boundaries, concentration of potassium being greater in the dark areas. A cross-section is chosen along which a distribution of potassium K_α radiation was further investigated (Figs. 4a and 4b).

On the basis of the results obtained, conclusions can be drawn that the segregation of potassium takes place in distinct points of grain boundaries in amounts about 8−10 times greater than on the grain surface.

Lg σ dependencies on reciprocal absolute temperature during cooling in various atmospheres obtained for natural magnetite after melting, for two synthetized catalysts on magnetite basis to which promotors were added by different methods (MB-1 and MB-2) and for one commercial sample of industrial catalyst (D), are shown in Fig. 5 (a, b, c and d).

The electric conductivity of all tested samples did not change uniformly with temperature. Two regions with different activation energies were observed. Calculated activation energies for intervals of lg σ linear dependence on $1/T$ in vacuum, nitrogen and air, are shown in Table 2.

c

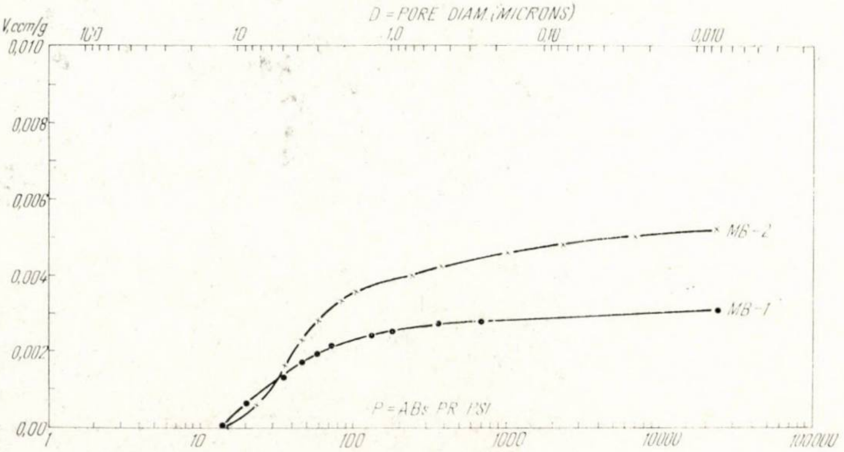

Fig. 2. — Total pore volume distribution *vs* pore radius of unreduced synthetized samples.

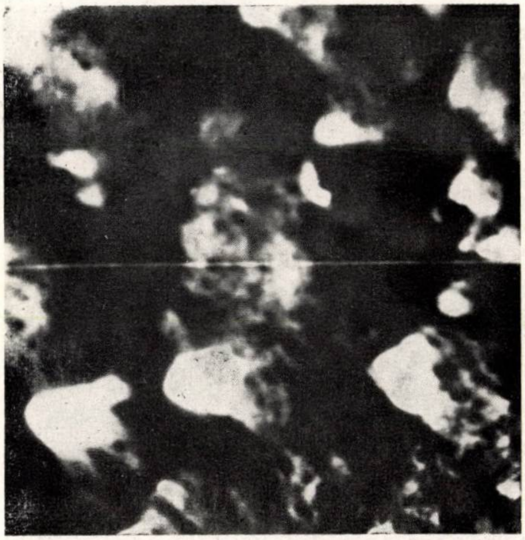

Fig. 3. — Electronic picture of MB—2 surface (with the marked line), × 280.

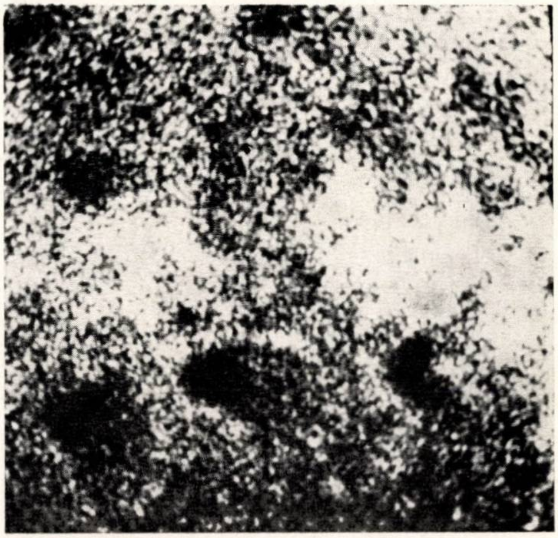
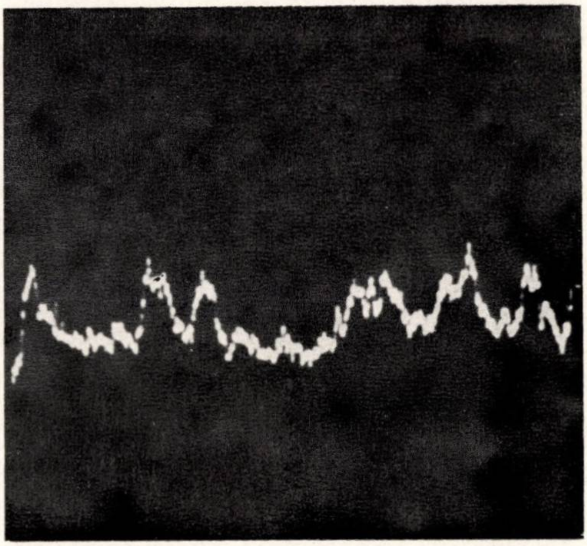


a



b

Fig. 4. — *a*, Electron microprobe exposure showing distribution of potassium; density of light spots proportional to concentration. b, Relative intensity of K_α radiation of potassium along the line marked on Figs. 3 and 4, proportional to concentration.

Differences in activation energies undoubtedly indicate that in lower temperature intervals predominates conductivity which, according to activation energy, corresponds to the surface conductivity of additives.[3] At higher temperatures, activation of defects in the magnetite mass with more consumption of energy and simultaneous diffusion of these defects over the surface of catalyst, takes place.

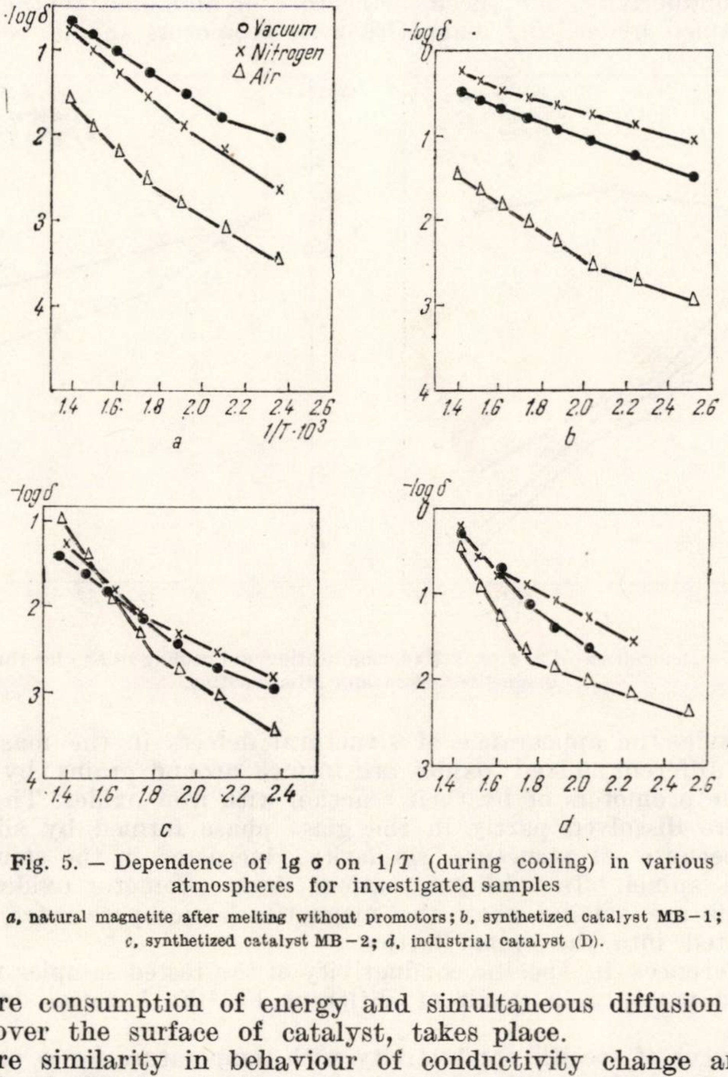


Fig. 5. — Dependence of lg σ on $1/T$ (during cooling) in various atmospheres for investigated samples

a, natural magnetite after melting without promotors; *b*, synthetized catalyst MB – 1; *c*, synthetized catalyst MB – 2; *d*, industrial catalyst (D).

More similarity in behaviour of conductivity change and closer values of calculated activation energies, in the lower and higher temperature intervals for the sample MB-2 and D catalyst, can be ascribed to the effect of similar procedure of promotor addition during catalyst synthesis. The effect was also manifested in higher activation energies in comparison with the MB-1 sample, to which promotors were added in another way.

[3] V. I. SPICYN, B. V. EROFEEV and I. V. MIHAJLENKO, *Izvest. Akad. Nauk S.S.S.R. Otdel. khim. Nauk*, **10**, 2117 (1969).

While explaining the effect of the mode of promotor addition on electric conductivity, the specific structure of ammonia synthesis catalysts obtained by melting magnetite with promotors should be kept in mind. Besides the appearance of structural defects in the mass during melting, different mixed oxides are formed around grains by interaction of the promotors or by their reaction with iron oxides. These compounds are dissolved partly in the glass phase formed by silica and, partly, because of structure similarity, incrusted in the structure of magnetite spinel.[4] In addition, cations from promotor oxides, whose ionic radia are smaller than the magnetite lattice parameter, can be incorporated into the spinel lattice.

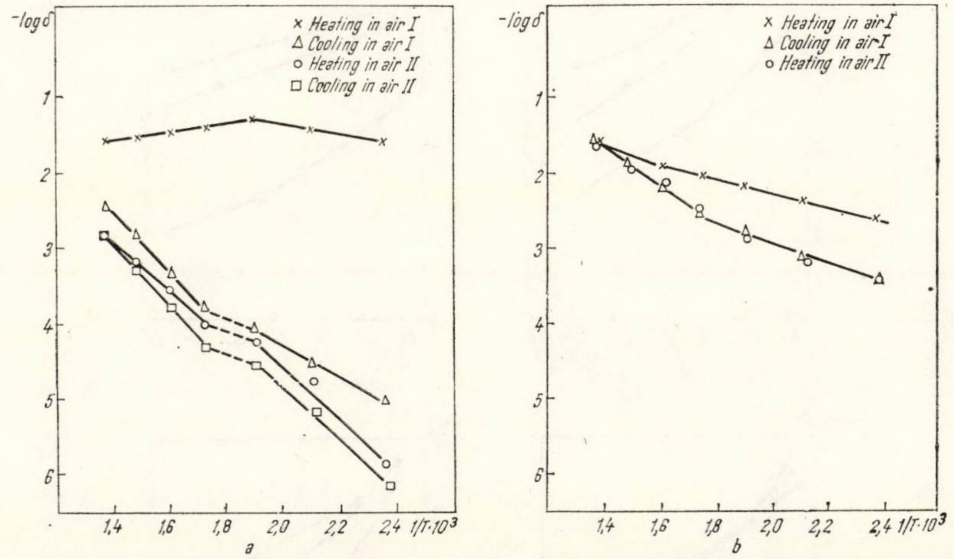

Fig. 6. — Dependence of lg σ on $1/T$ (during heating and cooling in air) for the natural magnetite before and after melting.

Differences in specific conductivity of the tested samples might be considered partly as a result of different Fe^{+2}/Fe^{+3} ratios in melted catalysts.

Changes of specific conductivity with temperature for a nonmelted and melted sample of natural magnetite are shown in Fig. 6.

Nonmelted natural magnetite shows characteristic behaviour of conductivity during heating. The conductivity decrease at temperature over 250°, which is not observed in melted magnetite, may be ascribed to the surface oxidation of magnetite grains, which takes place in air within this temperature range. Comparison of the first and the second cycle of heating in air shows that, in contrast with melted magnetite, the conductivity in the natural magnetite was not stabilized during the first cycle of heating.

---

[4] R. Hosemann, *Chem. Ind. Techn.*, **42**, 21, 1325 (1970).

Activities of synthetized catalysts samples and a commercial sample of industrial catalyst, expressed by rate constant of ammonia synthesis reaction are listed in Table 3.

Table 3

Results of catalyst activity determination. Rate constant, k, of the reaction of ammonia synthesis (for Temkin-equation coefficient $\alpha = 0.75$)

t°C	Catalyst sample		
	MB–1	MB–2	*D*
400	—	0.01	0.05
425	—	—	0.16
450	0.08	0.25	0.48
475	—	0.51	1.38
500	1.11	0.90	3.07
525	—	—	4.95
550	3.76	3.28	6.40

The catalyst activity of the MB–1 sample was somewhat higher as compared to MB–2, which could be expected according to its more favorable Fe^{+2}/Fe^{+3} ratio, as well as to more convenient binding of promotors to the magnetite catalyst base. The lower activity of the synthetized samples in comparison with that one of the most active industrial catalysts, resulted partly from the technology of laboratory sample synthesis which could not completely simulate the industrial catalyst production conditions, and partly from the higher content of silica in natural magnetite.

CONCLUSIONS

Promotors addition procedure has various effects on the investigated physico-chemical, textural and structural properties of unreduced catalysts for ammonia synthesis.

The applied methods have shown that those effects are more pronounced in the microstructure formation, than in the development of the specific surface and in the character of porous structure of unreduced samples.

The mode of promotor addition was reflected on electric conductivity changes and activation energies of conduction in investigated conditions, too.

Results obtained for the catalytic activity of reduced synthetized samples are in agreement with the conclusions concerning the effect of promotor addition procedure on the properties of unreduced catalysts.

POLAROGRAPHIC BEHAVIOUR OF BISMUTH (III) IN ACID PERCHLORATE SOLUTIONS

C. DRĂGULESCU, ANA NIMARĂ, I. JULEAN and D. MARANDIUC

Chemical Research Center
Bd. Mihai Viteazul 24, Timişoara, Romania

Received November 4, 1972

The polarographic behaviour and the kinetics of Bi (III) reduction in acid solutions, pH 0–2, were investigated. A scheme of the electrode reaction is proposed consisting in the participating of species $BiOH^{2+}$ in the slow stage. The heterogenous rate constant of the electrode process and the activation energy for both waves at different pH were determined.

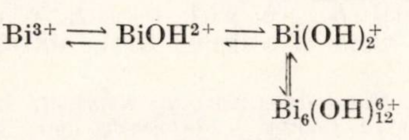
Kinetics of electrode processes and determination of electroactive species for hydrolyzing metallic ions are complex phenomena.

The great influence exerted by pH on reduction processes of some metals in acid solutions pointed out the importance of hydrolyzed species in these processes.

In order to elucidate the dependence of kinetics of the electrode processes on the pH of the solution, the influence of acidity on reduction rate of bismuth ions have been studied using the dropping mercury electrode and the hanging mercury drop electrode.

Taking into account the great hydrolyzing tendency manifested by bismuth (III) even in acid solution, we thought interesting to study the behaviour of hydrolyzed species in the electrode process.

Polarographic determinations depending on pH show the existence of two waves, that denote the establishment of some equilibria in solution. pH-metric data [1,2] and the spectrophotometric as well cyclic voltametric data [3] show the existence of the following hydrolyzed species within the pH range of 0–2 :



$$\begin{tikzcd} Bi^{3+} \arrow[r, leftrightharpoons] & BiOH^{2+} \arrow[r, leftrightharpoons] & Bi(OH)_2^{+} \arrow[d, leftrightharpoons] \\ & & Bi_6(OH)_{12}^{6+} \end{tikzcd}$$

[3] C. Drăgulescu, A. Nimară and I. Julean, *Chem. Analit.*, **17**, 631 (1972).

As to the species reduced on the electrode the conclusions drawn in the literature are still questionable. Losev and Gorodetki[4] consider that at pH 0—2 the reduced species is $BiOH^{2+}$, resulted both through Bi^{3+} hydrolysis and hexamer dissociation.

The later results obtained by Moorhead and Lipscey[5] show that the first wave represents the reduction of both Bi^{3+} and $BiOH^{2+}$, while for the second wave they are ready to accept Goward's hypothesis[6] that this wave is due to the reduction of $Bi(OH)_2^+$ in rapid equilibria with the hexamer $Bi_6(OH)_{12}^{6+}$.

The present work deals with the investigation of the electrode process mechanism in order to obtain information about the nature of reducing species and, indirectly, about the hydrolyzed species existent in the solution. This was obtained by determining the kinetic parameters k^0, αn function of pH, and the temperature — then, out of the rate constant values, the activation energy was determined knowing this to be a direct measure of the energy required by structural changes of the reacting particle.[7]

EXPERIMENTAL

Measurements have been carried on PO4 polarograph and PHM 25 pH-meter.

The capillary had the following characteristics : $h = 58$ cm, $t = 3.5$ s, $m = 2.09$ mgS^{-1} in $HClO_4 + NaClO_4$ 1 M solution, open circuit. A slow cyclic polarization technique was applied using 0.8 V.p.m. potential change rate.

The ionic strength has been maintained constant with sodium perchlorate at 1.0 mol l^{-1}.

RESULTS AND DISCUSSION

Polarographic and cyclic voltametric curves show that the electrode process is irreversible, and that in the process hydrogen ions are taking part, since the half-wave potential becomes more negative with the increase of pH.

The kinetics of the electrode process was followed by analysis according to the method given by Meites and Israel[8] by means of the following relation

$$E = \frac{0.0591}{\alpha n_a} \log \frac{1.349\, k^0 t^{1/2}}{D^{1/2}} - \frac{0.0542}{\alpha n_a} \log \frac{I}{I_d - I}$$

where k^0 is the heterogeneous rate constant of the electrode process at an arbitrary potential $E' = 0$, with respect to the saturated calomel electrode; t is life time of a drop; D, the diffusion constant of the depolarizer ; α, the electron transfer coefficient ; n_a, the number of electrons participating in the slow stage of the process ; I is the maximum current at a potential E and I_d is the diffusion current. From the slope of the plot of E *vs*.log $[I/(I_d - I)]$ the value of αn_a is obtained and the intercept having the meaning of the half-wave potential, yields the constant k^0.

By the method suggested by Nicholson[9] from cyclic voltammetric curves by means of relation

$$\psi = \gamma K_S / \sqrt{\pi a D}$$

where ψ = kinetic parameter tabulated *vs* experimental ΔE_p

$$\gamma = \left[\frac{Da}{D_R}\right]^{1/2} \cong 1$$

$$a = \frac{nFv}{RT}$$

v = potential change rate V_{sec}^{-1}

Values of rate constants for the two mentioned waves are presented in table 1.

Table 1

Dependence of the heterogeneous rate constant on pH ; $C_{Bi}^{3+} = 1 \cdot 10^{-3}$M 1 M NaClO$_4$; 25°C

pH	First wave		Cyclic voltammetry	Second wave	
	Polarographic			Polarographic	
	k^0	αn	k^0	k^0	αn
0	$4.49 \cdot 10^{-4}$	0.797	$6.5 \cdot 10^{-4}$	—	—
1	$1.39 \cdot 10^{-3}$	0.757	$2.26 \cdot 10^{-3}$	—	—
1.12	$3.76 \cdot 10^{-3}$	1.77	$2.38 \cdot 10^{-3}$	$1.36 \cdot 10^{-4}$	0.786
1.30	$4.56 \cdot 10^{-3}$	1.77	$2.87 \cdot 10^{-3}$	$8.92 \cdot 10^{-5}$	0.786
1.50	$2.22 \cdot 10^{-3}$	1.475	$1.87 \cdot 10^{-3}$	$6.31 \cdot 10^{-5}$	0.786
1.90	$1.49 \cdot 10^{-3}$	1.44	$1.00 \cdot 10^{-3}$	$3.24 \cdot 10^{-5}$	0.786

Data in table 1 show that in the pH range 0—1.3 the increase of pH brings about the increase of the cathodic process rate. This can be accounted for by presuming the existence of a chemical reaction preceding the discharge phase and consisting in Bi^{3+} ions passing into hydrolyzed ions.

The increase of the rate constant with pH confirms the De Maeyer and Kustin's hypothesis[10] by which cation reduction is easier when water molecules in the hydrated shell of the metallic ion are replaced by OH^- ions, which act as a catalyst, accelerating the electron transition between the electrode surface and the particle in discharge.

---

[10] L. De Mayer and K. Kustin, *Ann. Rev. Phys. Chem.*, **14,** 12 (1963).

When pH is beyond 1.3, formation of polymeric species $Bi_6(OH)_{12}^{6+}$ takes place in solution and as its concentration increases, the rate constant decreases, probably due to diminution of $BiOH^{2+}$ concentration. For the second wave also a decrease of rate constant is established with increase of pH, then the process irreversibility increases, which is confirmed also by voltammograms shape.

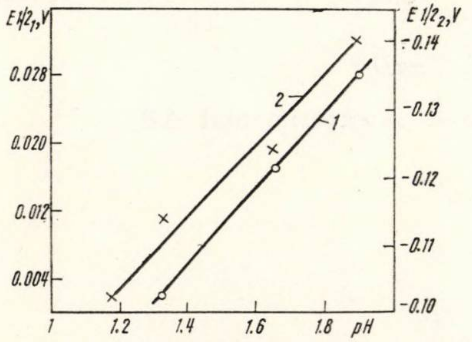

Fig. 1. — The change in the half-wave potential on variation of the pH of the solution. 1.0×10^{-3} M Bi^{3+} ; 1 M $NaClO_4$.

1, First wave; *2*, Second wave.

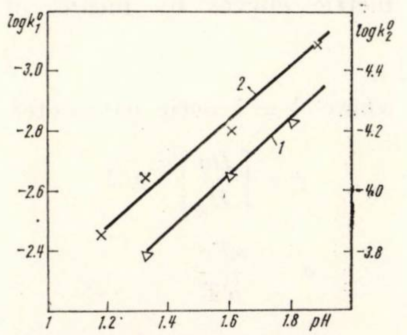

Fig. 2. — The change in the heterogeneous rate constant on pH of the solution. 1.0×10^{-3} M Bi^{3+} ; 1 M $NaClO_4$.

1, First wave; *2*, Second wave.

The change in the half-wave potential and the constant k^0 on variation of the pH of the solution are plotted in figs. 1 and 2 and show that hydrogen ions are participating in the slow stage of the electrode process. By inserting the slopes obtained corresponding to these straight lines into the following relation

$$\frac{\Delta E\,1/2}{\Delta \mathrm{pH}} = \frac{0.0591}{\alpha n_a} \qquad \frac{\log k^0}{\Delta \mathrm{pH}} = \frac{0.0591}{\alpha n_a}\,\mathrm{p}$$

we could determine the number of hydrogen ions that take part in the process, and for both waves, values very close to unity were obtained. This means that in the slow stage of the process only one electron is taking part. The resulting value of $p = 1$ leads to the conclusion that the slow electrode process involves only one hydrogen ion. The probable electrode process is occurring according to the following scheme

$$BiOH^{2+} + H^+ + e^- \rightleftharpoons Bi^{2+} + H_2O$$

$$Bi^{2+} + 2e \rightleftharpoons Bi$$

Taking into account that the rate constant corresponding to the second wave is proportional to $[H^+]^1$ concentration we can presume the species $BiOH^{2+}$ for the second wave to result from reaction

$$Bi(OH)_2^+ + H^+ \rightleftharpoons BiOH^{2+} + H_2O$$

The scheme given above is in a good agreement with the one suggested by Lovrecek and Mekjavic,[11] who from galvanostatic determinations draw the conclusion that the slow stage of the electrode process is represented by the elimination of the first electron.

Confirmation of the above mentioned has been obtained studying the dependence of the rate constant on the temperature at different pH values, corresponding to different hydrolysis stages and determining the activation energy.

For the first wave, determinations were carried out at pH 0 and 1, results being given in figs. 3 and 4.

For a Bi^{3+} solution of pH 0 (fig. 3) it has been ascertained that within the range of 25–35°, the rate constant varies slightly. This being a proof that up to 35° the hydrolysis process develops very slowly. At temperatures higher than 35°, hydrolysis makes progress and consequently rate constant increases. Activation energy, determined from the slope, is of 3.07 kcal/mol for temperatures of 25–35°. This value is close to that of the activation energy for diffusion of metallic ions in water which, according to literature, is about 4 kcal/mol.[12] So, we are entitled to consider that at pH 0, the reduced species is the simple unhydrolyzed Bi^{3+} ion. For the range of 40–50° a value of 17.7 kcal/mo for the activation energy is obtained.

Carrying out the same determinations with a solution of pH 11 (fig. 4), when both Bi^{3+} and $BiOH^{2+}$ are present, it was found that up to 40° the rate constant increases and then remains approximately constant. This shows that over 40° bismuth is totally hydrolyzed, the value of activation energy being also of 17.5 kcal/mol.

The same determinations were carried out for the second wave at pH 1.60. The rate constant increases in this case, also with the increase of the temperature (fig. 5).

Temperature increase causes the two waves to fuse into a single one with a half wave potential of −0.05 V (SCE) that means that under the influence of temperature $Bi(OH)_2^+$ passes into $BiOH^{2+}$, the latter species participating in the reduction process. This is confirmed also by the slope, which gives a value of 17.3 kcal/mol, approximately identical in all the three cases.

[12] R. Parsons, "Handbook of electrochemical constants", Butterworths, London, 1959, p. 79.

In conclusion, the study of the mechanism of the electrode process allowed the identification of species formed at bismuth hydrolysis. Bi^{3+} species is present and reduced only in solution with pH=0. At a greater pH than 1 there appear the mononuclear species $BiOH^{2+}$ and $Bi(OH)_2^+$. The latter polymerizing rapidly in hexamer, the reduced species on the electrode being $BiOH^{2+}$. So, these hydrolyzed species behave as a series of successive complex compounds, only one of them being reduced on the electrode.

NEW COMPOUNDS OF YTTRIUM AND LANTHANIDES WITH N,N'-ETHYLENEDIANTHRANILIC ACID (EDAN)*

P. SPACU and EUGENIA IVAN

Center of Physical Chemistry, Dumbrava Roşie, 23
Bucharest – 9, Romania

Received October 20, 1972

A new series of lanthanide compounds with a ligand containing nitrogen, ethylenedianthranilic acid (EDAN) were prepared. The compounds have the general formula $Ln_2(EDAN)_3$ (Ln = La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Yb and Y) and contain 1 – 2 water molecules. The new synthetized compounds were characterized by their electronic spectra in UV and visible ranges as well as by IR spectra and X-ray Debyegrams which gave informations about their structural formula.

In these last years, the affinity of the lanthanide ions towards a wide variety of donor atoms was intensively investigated. It has been generally observed that the lanthanide ions have a marked preference to form chemical bonds with those ligands containing oxygen as the donor atom.[1]

Nevertheless, the possibility of chemical bond formation with ligands containing nitrogen as donor atom is not excluded. The case of the aminopolycarboxilic acids, whose geometry allows the aliphatic nitrogen atoms be tightly bound to the lanthanide ion and which is invoked by many authors,[2–6] is an example of interaction between nitrogen and the lanthanide ions.

The aim of the present note is to demonstrate the existence of this interaction in the lanthanide complexes containing N,N'-ethylenedianthranilic acid (EDAN) as coordinated ligand.

---

EXPERIMENTAL

REAGENTS

— Lanthanide chlorides and nitrates were prepared from lanthanide oxides (Johnson-Matthey — 99.9% purity, except for Eu_2O_3 — 98%) treated with diluted 1 : 1 hydrochloric acid and nitric acid, respectively.

— N, N′-ethylenedianthranilic acid (EDAN) molecular formula ($C_{16}H_{16}N_2O_4$) was prepared using the modified Frankel and Spero method [7] as well as the Sweet and Harris indications, [8] as follows : 4 moles of methyl anthranilate and 1 mole of ethylenebromide are refluxed for 6 hours at 140—150° on the oil bath. One must take care to keep the indicated temperature interval, otherwise at higher temperatures (over 160°) the products decompose and the reaction yield tends to zero. The product is cooled on ice and treated with 2n HCl to solve the excess of anthranilic acid, the insoluble dianthranilic ester being afterwards crystallized from ethanol as thin needles with mp = **117°**.

The esther is refluxed with 20% alcohol solution of KOH for 12 hours (pH = 8 — 9). The crystallized potassium salt is filtered, solved in water and treated with acetic acid (1 : 10 in water) up to pH=3, when the ethylenedianthranilic acid precipitates. The recrystallization is made from a 20% KOH alcohol solution (1 : 4 alcohol and water, respectively) by precipitation with acetic acid. Its melting point is 222—223°.

SYNTHESIS OF LANTHANIDE COMPOUNDS

4.5 g of EDAN are solved in 50 ml 2N NH_4OH, slightly heated to remove the excess of ammonia, diluted in 200 ml of water and then filtered. Alcohol is added to the filtrate up to 500 ml, to obtain a 0.03 M (pH = 7.5) solution. The lanthanides and yttrium react quantitatively with EDAN in the following way : 0.01 M (pH = 4.5—5) solution of lanthanide chloride is precipitated by the reagent prepared as shown above. One must take care that a slight excess of cation solution should be present, to assure the complete reaction. The precipitates are immediately formed in a few minutes at the room temperature, the pH being maintained at 5. The solid products are left to stay for 24 hours, then filtered, washed with water and absolute ethanol and dried in the air at the room temperature.

ELEMENTAL ANALYSIS

The lanthanide elements were estimated from their oxides obtained by the direct combustion of the compounds. Nitrogen, carbon and hydrogen were determined by microanalysis. The results of the chemical analysis are given in table 1.

The electronic spectra in UV were recorded for EDAN and all its synthetized compounds in 10^{-4} M absolute methanol or DMF solutions, as well as by reflectance on the solid state in MgO pellets (1 : 10 or 1 : 20). The absorption in the visible range was determined as reflectance spectra only for all the compounds obtained, as well as for hexahydrated lanthanide nitrates taken as standards.

The spectral measurements on solutions were carried out using a Zeiss VSU–2 spectrophotometer and those on the solid state using a Zeiss VSU–1 spectrophotometer with the corresponding attached reflectance device.

IR spectra were recorded for the solid EDAN and neodymium compound using pellets of KBr in suitable dilutions.

The IR spectra within 4 000 – 400 cm^{-1} range were recorded using a UR–10 spectrophotometer.

X – Ray Debyegrams were recorded on powders by means of the Debye-Scherrer method for EDAN and all synthetized compounds, using a TUR–M 60 equipment and the following radiations and filters :

– Cr $K\alpha_1$ ($\lambda = 2.28962$ Å) radiation and V filter for La, Ce, Pr, Nd compounds ;

– Fe $K\alpha_1$ ($\lambda = 1.93597$ Å) radiation and Mn filter for the Sm compound ;

– Co $K\alpha_1$ ($\lambda = 1.78892$ Å) radiation and Fe filter for Eu and Gd compounds ;

– Ni $K\alpha_1$ ($\lambda = 1.65784$ Å) radiation and Co filter for Tb and Dy compounds ;

– Cu $K\alpha_1$ ($\lambda = 1.54051$ Å) radiation and Ni filter for EDAN and Y, Ho, Er and Yb compounds.

The films were recorded using a microphotometer with photocell Carl Zeiss with automatic recording.

The diffractograms for EDAN and ytterbium compound were recorded using a HZG–1 (DDR) diffractometer, $CuK\alpha_1$ radiation and Ni filter. θ angles were transformed into d(Å) using the A. J. Rose standard tables.

RESULTS AND DISCUSSION

As results from the chemical analysis (table 1), the chemical formula of the synthetized compounds corresponds to $2Ln.3EDAN.nH_2O$ ($n = 1, 2$). The presence of water in such compounds influences the analytical results, especially the data concerning carbon and hydrogen, as happens in the case of the metal compounds containing aminobenzoic acids with substituted rings.[9] Usually, the water molecules are inserted within the crystalline lattice, the complexes occasionally containing one or more moles of water.

All the synthetized compounds are solid and very stable, their melting points being over 300°. Except the europium compound which is intense yellow-coloured, all the compounds of the lanthanides series are cream-coloured.

The solubility of these compounds is reduced and it does not exceed 10^{-4} M for the majority of ordinary organic solvents : ethanol, methanol, acetone, acetophenone, dioxane, chloroform, benzene, carbontetrachloride, methyl ethylcetone and no more than 10^{-3} M in dimethylformamide or dimethylsulfoxide. The insolubility of the synthetized compounds makes difficult the recording of the absorption spectra on solutions. Like the bisanthranilates of bivalent metals,[10] the scarce solubility in different solvents, a polymeric structure could be proposed in our compounds.

The absorption electronic spectra in UV of all the new compounds are similar to each other, either in shape or intensity log ε (solution) or 100-R (solid).

Fig. 1 shows, for this reason, the absorption spectra of EDAN and its compounds with La and Yb only, recorded on solutions of 10^{-4} M in methanol and DMF. Fig. 2 shows the same spectra recorded on the solid state, using pellets of MgO at the ratio 1 : 20. For other compounds, the two absorption spectra are summarized in table 2.

The absorption maxima occurring in the UV range are ascribed to the π electron system of the ligand.

As may be seen in figs. 1–2, EDAN presents the same absorption curve both in absolute methanol or DMF, while the corresponding absorption maxima of the compounds have exactly the same position in both solvents, but in DMF a marked increase in their intensity should be observed.

The reflectance spectra have the same two absorption maxima shifted with 10–15 nm towards higher wavenumbers, the shifts being probably due to the interaction between ligand (compound) and the crystalline lattice. The almost perfect identity between the absorption spectra recorded for the solid state and solution would indicate the lack of any structural changes of the compounds in solution or solid state.

[9] J. S. Decker and Frye Herchel, *Z. Naturforsch*, **21**, 522 (1966).

[10] S. Sandhu, S. Manhas, R. Mittal and S. Parnar, *Indian J. Chem.*, **7** 1051 (1969).

As may be seen in table 2, the absorption maxima of the coordinated ligand occurring in the reflectance or solution spectra are shifted towards higher wave numbers if they compared with those of the free ligand.

The shift of the maximum appearing at 260 nm is small (~5 nm), but nevertheless it becomes evident for heavier lanthanide ions. The other shift of the absorption maximum at 350 nm is more pronounced (10—12 nm) and it is maintained in all the series of compounds. The bandshifts mentioned above could be ascribed to the interruption of the "π" conjugation between the carboxylic group and the phenyl ring, as a consequence of nonplanarity between them, caused by the coordination requirements. The above assumption agrees with the chemical results and the X-Ray data which would indicate a polymeric structure.

3, $Yb_2EDAN_3.H_2O$

As far as the electronic spectra are concerned, the absorption bands occurring in the visible range could be assigned to the internal transitions between the spectral terms of the central metal ion.

The absorption bands of ethylendianthranilates with Pr, Nd, Dy, Ho and Er have been compared with the maxima occurring in the corresponding hexahydrated nitrates taken as reference.

As may be observed from table 3 the almost all absorption bands are shifted towards smaller wavenumbers (red shift).

The shifts were used to evaluate the mean covalency degree of the chemical bonds by means of the formula :

$$\delta' = \frac{1-\beta'}{\beta'} \cdot 100,^{11} \text{ where } \beta' - \text{is the nephelauxetic ratio,}$$

$$\beta' = \frac{\beta_{\text{complex}}}{\beta_{\text{aquo ion}}} = \frac{\tilde{\nu}_{\text{complex}}}{\tilde{\nu}_{\text{aquo ion}}}, \text{ and } \tilde{\nu}$$

are the wavenumbers of the same transition in the aquo ion taken as standard and complex.

The quantity δ′ represents a measure of the covalency degree of the metal-ligand chemical bond.

The assignments of spectral terms were made consulting the literature. [12,13]

As may be seen from table 3, the δ′ parameter assumes positive values for the majority of absorption bands, which indicates that the chemical bonds, with the oxygen atoms of carboxylic groups are more covalent than those with the water molecules.

---

[11] S. P. Sinha, *Spectrochim. Acta*, **22**, 57 (1966).

[12] N. K. Dutt and S. Gupta *J. Inorg. Nuclear Chem*, **33**, 4188 (1971).

[13] T. H. Siddall and N. E. Stewart, *J. Inorg. Nuclear Chem.*, **32**, 1147 (1970).

It should be mentioned that the bands are differently shifted, and hence different δ' are estimated. This could be explained by the fact that the "*f*" orbitals are differently involved in the chemical bonding, function of the stereochemistry of the complex.

It should be also noted that the covalency degree δ' assumes higher values for Pr(f^2) and Nd (f^3), lower for Er (f^{11}), zero or negative values for Dy(f^9) or Ho(f^{10}) ethylenedianthranilates.

This fact should be explained by the lowering of the bond covalency due to the gradual filling with electrons of the "*f*" orbitals, which renders difficult the possibility of their participation to the chemical bond formation. The IR spectra of EDAN and its compounds with lanthanides were analyzed comparing to vibration frequencies characteristic to the groups able to coordinate. The assignment was empirically made using the data [14,15] for similar amino acids.

The intensity changes of the carboxylic and CN frequencies going from the free ligand to the coordinated one constitute an obvious indication of complex formation. If the vibration frequency which occurs at 1670 – 1650 cm^{-1} is characteristic for the anthranilic acids with internal hydrogen bonds, the frequencies at 1610 and 1555 cm^{-1} in neodymium compound correspond to the antisymmetric vibrations of the ionized carboxylic group. Moreover, the vibration $\nu_{C=O}$ of the unionized carboxylic group does not occur in the IR spectra of the compound. The existence of these changes proves the coordination of carboxylic groups to the lanthanide ion.

The intense and narrow band at 1420 cm^{-1} has been ascribed to the symmetric vibration ν_S(CCN) of the aliphatic group, moved by coordination at 1400–1395 cm^{-1}, and at the same time increased in intensity, due to the presence in the same region of the symmetric vibration of COO$^-$.

Besides oxygen coordination, the changes in the C–N frequencies prove also the nitrogen coordination to the central metal ion.

The vibration characteristic to the NH group appears in EDAN as a narrow and intense band at 3375 cm^{-1} and in the coordination compounds at 3370–3340 cm^{-1}, broadened (due probably to the polymeric associations by the intermolecular hydrogen bonds).

The X-ray diffraction for EDAN leads to similar Debyegrams and diffractograms. Table 4 shows the d expressed in [Å] for the main diffraction lines of diffractograms.

The röentgenograms recorded for all the synthetized ethylenedianthranilates do not present any diffraction line, proving the amorphous state and high molecular weight.

The Debyegrams recorded for La, Ce, Pr, Nd, Sm, Eu, Gd, Dy, Er, Yb and Y compounds present two halos within 1.5–2.5 [Å] and 2.5–6.3 [Å]. The first halo is less obvious for the first lanthanides but

3.92	67.5	1.78	17.0

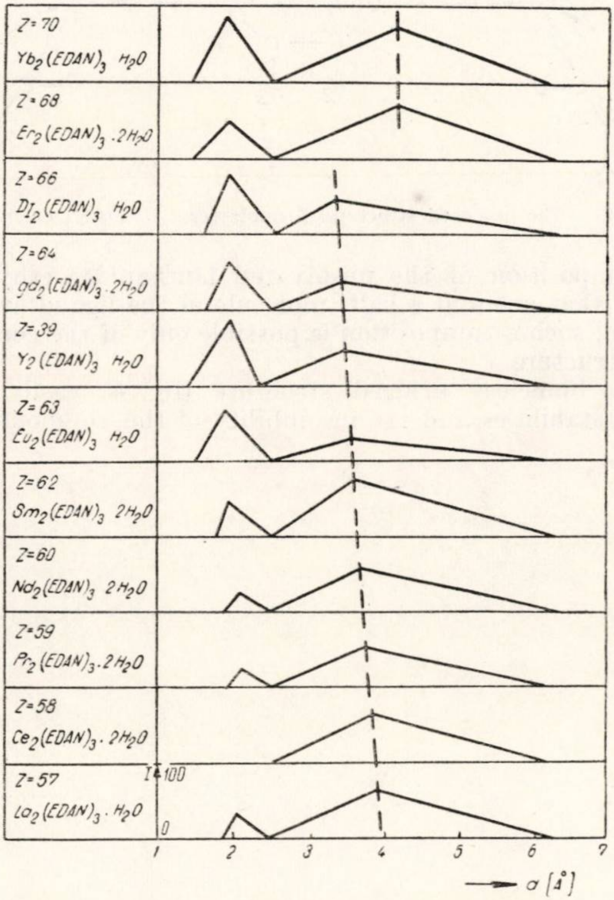

Fig. 3. – Debyegrams of $Ln_2EDAN_3.nH_2O$ compounds.

increases in intensity for heavier ones. The maximum of the second halo at 3.4–4.2 [Å] varies linearly with *Z* in the sequences La–Dy (including *Y*) and Er–Yb, as shown in figure 3.

Like the organic polymers, the halo-shape of the diffraction effects appearing in Debyegrams shows the amorphous and polymeric structure of the synthetized compounds, different from the roëntgenograms of the former lanthanides salts and original EDAN.

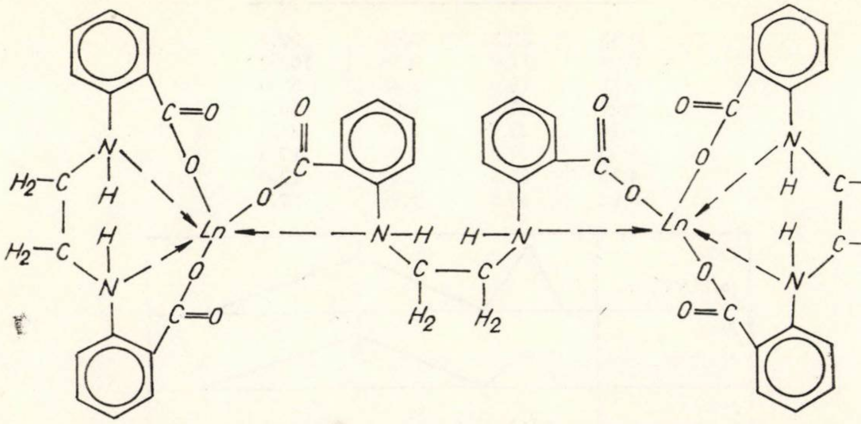

Fig. 4. – The proposed structural formula for Ln_2EDAN_3 compounds.

The composition of the unsolvated lanthanides ethylenedianthranilates shows that one and a half molecule of the ligand are attached to a metal atom; such a composition is possible only if the compounds have a dimeric structure.

Such a binuclear bridged structure (fig. 4) easily explains the high thermal stabilities and the insolubility of the compounds in organic solvents.

LANTHANIDE COMPOUNDS WITH HYDROCHLORIC PALUDRINE

ILEANA ALBESCU

Center of Physical Chemistry, str. Dumbrava Roşie 23,
Bucharest, Romania

Received September 28, 1972

The present paper describes the syntheses used to obtain some new compounds of lanthanides with hydrochloric paludrine, pald. HCl, compounds of the type: $(\text{pald. HCl})_n\ \text{LnCl}_3$, where $\text{Ln} = \text{Nd}-\text{Y}_b$. The new combinations were structurally characterized by means of their electronic absorption spectra.

In the previous papers [1-4] we have studied the effect of paludrine basis upon the lanthanide halides. Later on we directed our works also on the hydrochloric paludrine, pald. HCl, and on the thiocyanic paludrine, pald. HSCN, in order to obtain new types of combinations.

The aim of the present paper is the study of the systems:

$$\text{pald HCl}-\text{LnCl}_3 \qquad \text{Ln} = \text{Nd} - \text{Yb}$$

$$\text{and} \quad \text{pald HSCN}-\text{Ln(SCN)}_3 \qquad \text{Ln} = \text{Nd,Sm.Tb}$$

as regarding their syntheses, their physico-chemical properties and the analyses of their electronic spectra in order to establish their bond types.

There are two possibilities to synthetize the new compounds:

1) syntheses carried out in solution, using anhydrous reagents, in anhydrous solvents and in inert gas medium.

2) syntheses carried out in the first stage in molten salts followed by an extraction, refluxing with THF and then the concentration and the removal of the solvent; in this case hydrated salts were initially used, the subsequent working operations being made in inert gas medium too.

In an intermediate stage Ln(SCN)_3 was obtained in order to be used in the preparation of the new compounds with thiocyanic paludrine.

EXPERIMENTAL

1. *pald $HCl.LnCl_3$* Ln = Nd, Sm, Eu, Gd, Dy, Ho, Yb.

A mixture of anhydrous $LnCl_3$ or adduct, $LnCl_3$.xTHF, and pald. HCl in a molar ratio 1 : 3 is refluxed in a minimum amount of anhydrous methanol for two hours. The solution is evaporated under vacuum on P_4O_{10} till the complete removal of the solvent and the crystals thus obtained are refluxed for 10 minutes with a minimum quantity of THF. The solution is rapidly filtered at heat; from the filtrate a precipitate can immediately be separated as a gel which by stirring becomes crystalline and is coloured according to the nature of the metal ion.

All the working operations are made in inert gas medium as we have mentioned in the previous paper. [1-4] The chemical analysis of the compound corresponds to the above mentioned formula.

2. *(pald $HCl)_nLnCl_3$* n = 2 Ln = Nd, Sm, Eu, Yb

n = 3 Ln = Gd, Dy, Ho.

Besides the compound we have mentioned at point 1° as a main product and with a high efficiency one obtains in the filtrate, after 3—6 days concentration under vacuum crystals coloured in yellow (Sm), violet (ND, Yb), pink (Eu, Dy), cream (Dy). All the compounds thus synthetized are unstable in air, soluble in alcohol, acetone, THF whereas the compounds of general formula pald. $HCl.LnCl_3$ are more stable.

With a view of preparing compounds of the general formula (pald. $HCl)_nLnCl_3$ in a more varied series and with a better efficiency our observations led us to a second method: in a first stage the synthesis is carried out in molten salts, then it is continued in solution by extraction with solvent. The general development of the synthesis runs as follows:

3. *(pald $HCl)_n.LnCl_3$* n = 2 Ln = Yb

n = 3 Ln = Nd, Eu, Dy, Ho.

n = 4 Ln = Sm

n = 5 Ln = Gd

A mixture of $LnCl_3.nH_2O$ and pald. HCl in a ratio 1 : 3 is carefully melted in a China crucible lest the temperature should exceed 210°, then all the quantity becomes a homogeneous paste, it is treated with 25 ml anhydrous methanol or THF; the operation being now made in nitrogen atmosphere. The extract is stirred and left to settle the unsoluble part as a secondary product which contains the oxychloride of lanthanide. After 6—8 hours it is filtered and the extract is refluxed in a nitrogen atmosphere for two hours. During the refluxing the colour of the solution becomes more intense according to the nature of the metal ion: intense yellow (Sm, Ho), light yellow (Gd, Eu), violet (Nd), pink yellow (Dy), violet yellow intense (Yb). After refluxing the solution is concentrated under vacuum on P_4O_{10}; after 2—3 days the glue obtained becomes crystalline. The above mentioned compounds have been identified at the chemical analysis. The compounds thus prepared as well as the compounds which were synthetized at point 2° are unstable in air, soluble in alcohol, acetone, THF.

4. *(pald $HCl).3LnCl_3$* Ln = Dy, Ho

In this case after refluxing, the solution extracted from melting with THF deposits a white crystalline precipitate, before it is concentrated under vacuum in order to lead to compounds of type (pald $HCl)_3.LnCl_3$; the precipitate is separated by filtration, washed with THF and dried under vacuum. The chemical analysis of the compound thus obtained leads to the combination of general form, pald. $HCl.3LnCl_3$

These new combinations are stable only in the absence of humidity ; they are kept in nitrogen atmosphere. They are unsoluble in alcohol, acetone and THF. Table 1 shows the chemical analysis of the new compounds

PSEUDOHALOGENO-COMPOUNDS

To obtain these combinations the anhydrous thiocyanates of lanthanides, used in the syntheses, have been prepared in an intermediary stage.

5. *pald* $HSCN.Ln(SCN)_3$ Ln = Nd, Sm, Tb

In the exchange reaction between $LnCl_3$ and KSCN in a methanol solution, $Ln(SCN)_3$ is obtained after the filtration of KCl ; a solution of pald HCl in methanol in ratio 1 : 3 is added and then the solution is refluxed for two hours in nitrogen atmosphere. After the removal of the solvent by evaporation under vacuum on P_4O_{10}, a crystalline mass is obtained, which is passed in a schlenk with frit G_3 and then it is extracted by refluxing with THF. The excess of pald HCl remains on the frit and the solution is concentrated under vacuum ; after 6–8 days a microcrystalline paste is obtained, which becomes crystalline in time.

For the syntheses the following ratios were used : 0.777 g $NdCl_3$ in 10 ml methanol with 0.914 g KSCN in 5 ml methanol. After the quantitative titration of KCl, supposing that in the solution there are 0.986 g $Nd(SCN)_3$ this solution is treated with 2.699 g pald HCl in 10 ml methanol which would correspond to the 1 : 3 salt-ligand ratio.

For the respective compound of Sm there were used : 0.5306 g $SmCl_3.1^{1/2}$ THF,0.4242 g KSCN and 1.266 g pald HCl respectively, keeping the proportion of the solvents.

For the compound with Tb we worked with : 0.5842 g $TbCl_3$, 0.6421 g KSCN and 1.917 g pald HCl recommending the respective proportions of solvent.

As regarding the refluxing with THF, 25–30 ml is the maximum quantity of solvent we recommend, for working with the best concentration of solution.

The compounds are coloured in : intense violet (Nd), dark yellow (Sm), pink yellow(Tb). They are not stable in air, decompose with water, are soluble in alcohol and THF.

6. (*pald* $HSCN)_3.Ln(SCN)_3$ Ln = Nd, Sm, Tb.

In this case the working operations are the same as those in the above mentioned syntheses till in the last stage of preparation a compound in the form of a glue is obtained. The latter is treated in ice with a minimum quantity of water till a precipitate appears. The chemical analysis shows the above mentioned combination.

The compounds are coloured in violet-brown (Nd), yellow (Sm), intense yellow towards pink (Tb) ; they are unstable in air, pass into glue if they lose water, are soluble in ethanol, THF, are kept in nitrogen.

The analytical results are given in table 2.

The electronic absorption spectra have been recorded in order to establish the structure of these compounds.

GENERAL DISCUSSIONS

The preparation of the new lanthanide compounds with pald HCl in the series of the studied elements strongly depends on two factors :

— the concentration of the initial components ; the concentration must be as much as possible near to the value of the molar concentration and it must be kept constant during the reaction. The observation is in concordance also with our studies in solution on the $MX\text{-}LnCl_3$, $M = Na$, K, Rb, Cs systems when we worked at the molar concentrations,[5-7] as well as with those in meltings concerning the existence and the stability of the $[LnX_n]^{n-3}$ ion.

— the second main factor refers to the difference of solubility in THF between paludrine basis and hydrochloride paludrine , the latter being unsoluble, as well as the difference of solubility between the compounds of general formulas, pald HCl. $LnCl_3$, and those of the type (pald $HCl)_n.LnCl_3$; the first ones precipitate and are separated from the THF

solution making possible the preparation of the latter ones in the crystalline form.

We remark that in the syntheses carried out in the first stage in meltings, hydrated halides are used because the anhydrous halides melt over 600° which does not allow their melting together with the ligand which

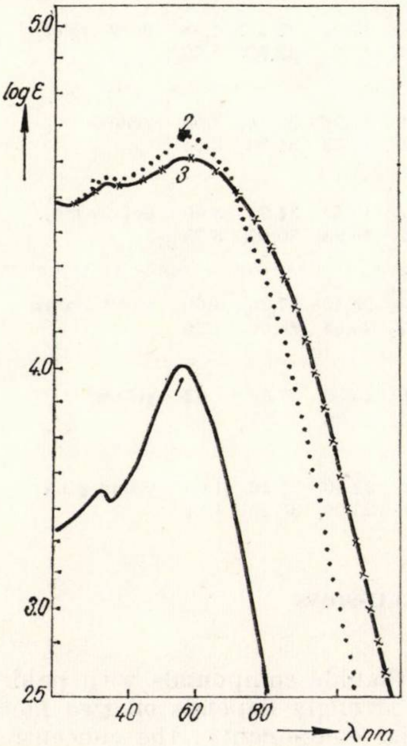

Fig. 1. – UV spectra of the Ho compounds. *1*, pald HCl ; *2*, pald HCl. $HoCl_3$; *3*, (pald HCl)$_3$.$HoCl_3$.

has the melting point at 212° ; through melting the situation of the anhydrous salts is somehow reached.

Since the compounds are not stable in air and are soluble in alcohol, their electronic spectra have been recorded on solution.

The combination pald HCl.$LnCl_3$ is the most stable from the whole series of compounds and it has permitted also the recording of its spectra on pellets.

Figs. 1,2 and 3 show the absorption spectra in UV and visible range of Ho and Dy compounds, against the corresponding aquo ions and anhydrous chlorides.

Unlike the compounds obtained with paludrine basis with the same elements,[1–4] the new combinations have, besides the characteristic band at 260 nm, proper to the benzene ring, a second absorption band at 233 nm of the pald HCl, slightly shifted towards smaller wavenumbers in the corresponding compounds.

To estimate the covalency degree of the chemical bands one evaluates the mean nephelauxetic ratio of the absorption band shifts reported to the absorption bands of the corresponding complex, $[Ln(H_2O)_6]^{3+}$.

The forbidden spin frequencies for the f^n configuration of the central ion are shifted by coordination.

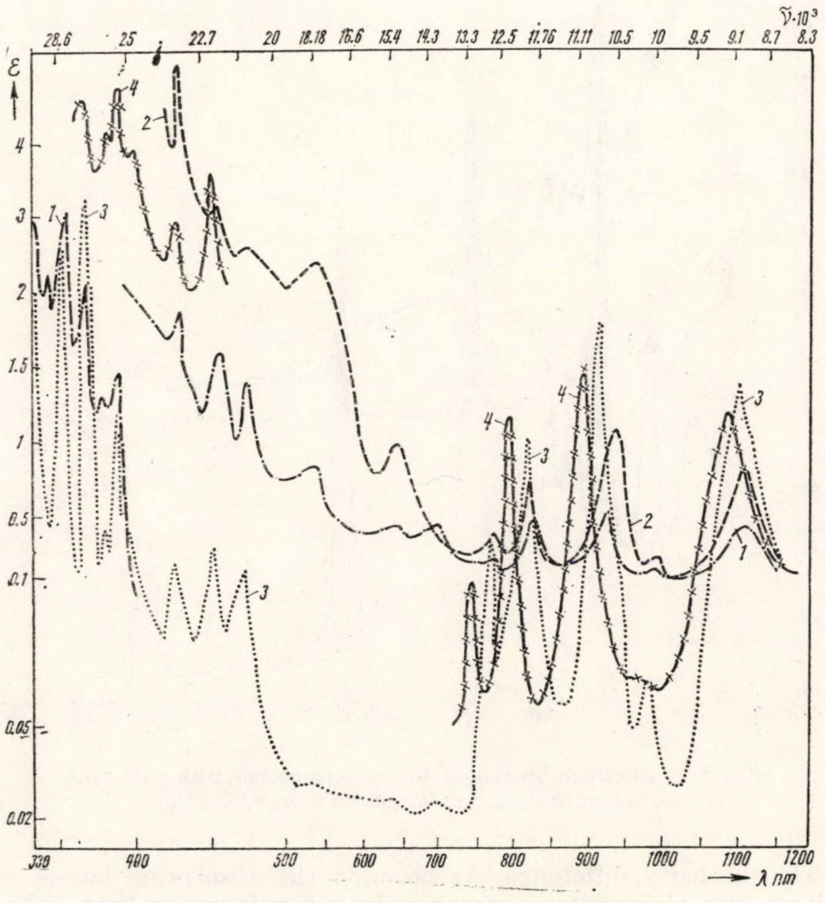

Fig. 2. — Electronic spectra of the Dy compounds with pald HCl.
1, pald HCl.$DyCl_3$; *2*, (pald HCl)$_3$.$DyCl_3$ *3*, $[Dy(H_2O)_6][NO_3]_3$ *4*, $DyCl_3$.

Like in the paludrine complexes the shifts assume low values in the present compounds. For each complex the δ_m parameter was calculated.

The most probable assignment of the absorption bands and of the corresponding transitions of the metal ion has been established like for the paludrine compounds. That is why table 3 presents the illustrative data only for Nd complexes.

As may be seen, δ_m values show a higher covalency degree of the chemical bands in our complexes than in the corresponding aquaion.

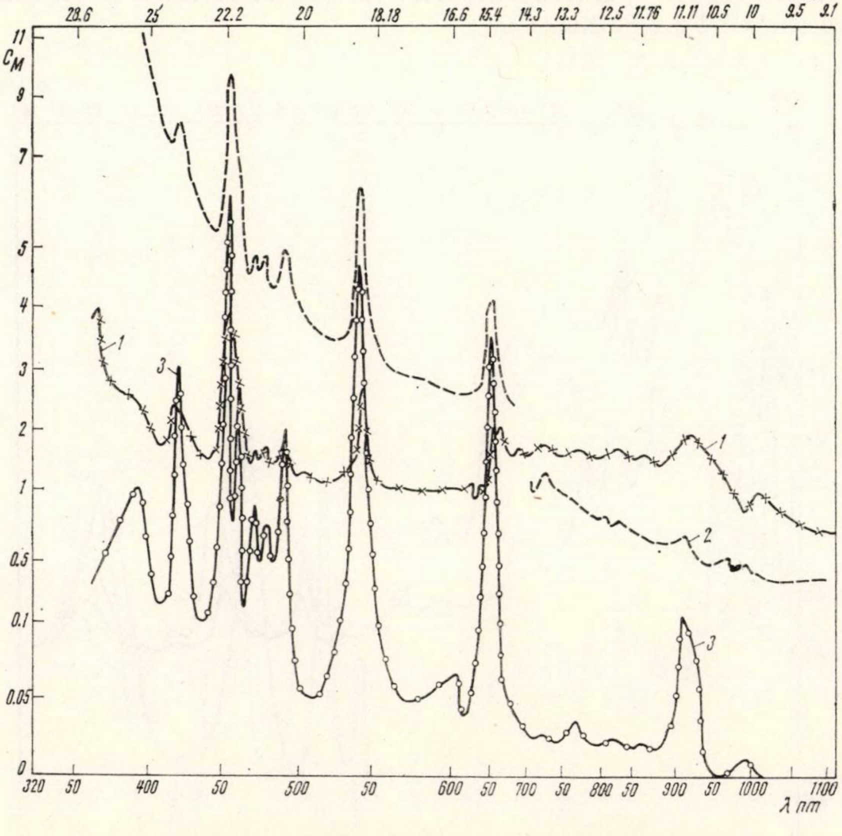

Fig. 3. — Electronic spectra of the Ho compounds with pald HCl.
1, pald HCl. $HoCl_3$; *2*, (pald HCl)$_3$.$HoCl_3$; *3*, $[Ho(H_2O)_6][NO_3]_3$.

The intensity difference $\Delta\varepsilon$ between the absorption bands of our complexes and those of the corresponding aquaions has been calculated by means of the simple formula :

$$\Delta\varepsilon = \varepsilon_{\text{mol complex}} - \varepsilon_{\text{mol aquaion}}$$

As may be seen from the data presented in Tables 5—6, the highest intensity differences which are noticed with δ_m parameter assume the highest values too.

The fact proves once more the coordination of the ligand to the rare earth metal ion.

Further researches on this line will follow in forthcoming papers.

CONTRIBUTION À L'ÉTUDE DE L'HYDROLYSE DE L'ION UO_2^{2+} EN MILIEU PERCHLORIQUE

MARIA MAVRODIN-TĂRĂBÎC
Centre de Chimie Physique — Bucarest,
31, str. Galați

Reçu le 5 juillet 1972

On détermine, par la méthode de la « fonction de formation » et la méthode « core + links », la nature des espèces ioniques formées par l'hydrolyse de l'uranium (VI). On tire la conclusion que, si jusqu'au pH = 2,5, le seul ion d'uranium (VI) qui se forme dans la solution est l'ion UO_2^{2+}, à des valeurs de pH>2,5, l'ion UO_2^{2+} hydrolyse par une suite de réactions qui mènent, même dans des solutions très diluées, à la formation des complexes polynucléaires du type « core + links », caractérisés par la formule générale $UO_2[(OH)_2UO_2]_n^{2+}$.

Tel qu'il résulte de l'analyse des travaux, souvent contradictoires, effectués ces derniers temps,[1–16] l'étude de la nature des espèces ioniques qui se forment par l'hydrolyse de l'uranium (VI) représente un domaine de recherche très important et très actuel.

Vu la grande complexité des réactions d'hydrolyse de l'uranium (VI), pour pouvoir déterminer exactement la nature et la stabilité des espèces ioniques qui se forment dans la solution, nos études sur le système perchlorate d'uranyle-eau, effectuées dans un autre travail [17] par voie spectrophotométrique et par l'analyse mathématique différentielle des courbes pH-métriques, ont été vérifiées et complétées dans ce travail, par *la mé-*

thode de la «fonction de formation», élaborée par Bjerrum[18] — pour le cas général des complexes en solution — et adaptée par Ahrland[19] — pour le cas spécial des réactions d'hydrolyse et par la méthode «*core + links*», élaborée par Sillen[20] pour l'étude des complexes polynucléaires.

L'étude des équilibres hydrolytiques par une méthode générale utilisée pour les complexes en solution est justifiée par le fait que les réactions d'hydrolyse peuvent être considérées comme des réactions de formation des complexes, dans le cas de l'ion UO_2^{2+} — en qualité d'ion central — avec les ions OH^- — en qualité de ligand —, l'ion d'uranyle représentant une constellation d'atomes parfaitement stable dans toutes les conditions du milieu de réaction.

PARTIE EXPÉRIMENTALE

RÉACTIFS

Perchlorate d'uranyle, $UO_2(ClO_4)_2\ 6\ H_2O$ (*p.a.* Th. Schuchardt). On a préparé une solution «stock» approximativement 0,1 N, dont on a obtenu, en diluant avec de l'eau bidistillée, les solutions de perchlorate d'uranyle de différentes concentrations : 0,02 N, 0,05 N, 0,01 N, 0,001 N.

Les concentrations de ces solutions ont été vérifiées par voie gravimétrique (évaporation et calcination à l'état d'oxyde U_3O_8).

Perchlorate de sodium, $NaClO_4$ (*purum,* Merck). Il a été utilisé après trois recristallisations et séchage à 110°C.

Hydroxyde de sodium (*p. a.* Merck). Les solutions utilisées ont été préparées en diluant une solution «stock» approximativement 0,1 N. La concentration des solutions de NaOH a été établie avec du phtalate acide de kalium.

Acide perchlorique, $HCl\ O_4$, (*p.a.* Merck) de concentration d'environ 75%. On a utilisé des solutions approximativement 0,1 N, analysées par titrage alcalimétrique.

APPAREILS

On a utilisé un pH-mètre Radiometer — Copenhagen (électrodes de verre et calomel). Les déterminations ont été faites dans une installation fermée, spécialement construite.

MODE DE TRAVAIL

Les déterminations pH-métriques ont été effectuées en titrant les solutions de perchlorate d'uranyle dans lesquelles on a ajouté auparavant une quantité d'acide perchlorique ; les titrages ont été faits en utilisant une solution de NaOH 0,1 M, le domaine de pH étudié étant compris entre 1,6 ÷ 4,5. Pour tirer des conclusions sur l'influence de la concentration sur la nature des espèces ioniques qui se forment par l'hydrolyse, on a travaillé avec des solutions de perchlorate d'uranyle de différentes concentrations, comprises entre 0,1 ÷ 0,001 M.

---

[18] N. Bjerrum, Thèse, Copenhaga (1948).

[19] S. Ahrland, *Acta Chem. Scand.*, **3**, 374 (1949).

[20] L. G. Sillen, *Acta Chem. Scand.*, **9**, 179 (1955).

L'influence de la force ionique a été évaluée en effectuant des déterminations pour chaque concentration, à quatre forces ioniques : $I = 0,5$; 1 ; 1,5 et 2, réalisées avec du $NaClO_4$.

(À mentionner que tous les titrages ont été répétés trois fois, les valeurs du pH représentées graphiquement et utilisées dans le calcul étant les valeurs moyennes. Les valeurs d'équilibre ont été obtenues après 60 secondes d'agitation continue.)

RÉSULTATS ET DISCUSSIONS

1. L'ÉTUDE DU SYSTÈME PERCHLORATE D'URANYLE – EAU PAR LA MÉTHODE DE LA « FONCTION DE FORMATION »

Si l'on élimine, conformément aux déterminations spectrophotométriques, la formation des polymères $(UO_2)_2$, $(UO_2)_3 \ldots (UO_2)_n$, dans les solutions aqueuses du perchlorate d'uranyle il existe — théoriquement — la possibilité de la formation des séries de complexes suivantes :

— mononucléaires MA, MA_2, MA_3 . . . .

— binucléaires M_2A, M_2A_2, M_2A_3 . . . .

— *m*- nucléaires M_mA, M_mA_2, M_mA_3 . . . .

La sélection des espèces ioniques qui se forment réellement dans la solution a été faite conformément à la méthode de Bjerrum en calculant $\bar{n}$, le nombre moyen de ligands OH^- liés à l'ion central d'uranyle et en analysant les courbes de la fonction de formation du système pour les différentes concentrations de l'ion UO_2^{2+}.

Les relations fondamentales utilisées dans le calcul ont été les suivantes :

$$\bar{n} = \frac{C_A - (A)}{C_M} \tag{1}$$

dans laquelle :

— C_A = la concentration totale du ligand (OH^-), connue dès les données initiales du travail :

$$C_A = (A) + (MA) + 2(MA_2) + \ldots + (M_2A) + 2(M_2A_2) + \ldots$$
$$\ldots + (M_mA) + 2(M_mA_2) + \ldots \tag{2}$$

— C_M = la concentration de l'ion central (UO_2^{2+}) également connue dès les données initiales du travail :

$$C_M = (M) + (MA) + (MA_2) + \ldots + 2(M_2A) + (M_2A_2) + \ldots$$
$$\ldots + m((M_mA) + (M_mA_2) + \ldots) + \ldots \tag{3}$$

— A = la concentration du ligand « libre » déterminée par la méthode pH-métrique.

La courbe de la fonction de formation du système a été obtenue en représentant $\overline{n}$ en fonction de (A) et est définie par l'équation :

$$\overline{n} = \frac{\beta_1'(A) + 2\beta_2'(A)^2 + 3\beta_3'(A)^3 + \ldots + (M)\,\beta_1''(A) +}{1 + \beta_1'(A) + \beta_2'(A)^2 + \beta_3'(A)^3 + \ldots + 2(M)(\beta_1''(A) +}$$
$$\frac{+\, 2\beta_2''(A)^2 + \ldots + (M)^{m-1}(\beta_1^{(m)}(A) + 2\beta_2^{(m)}(A)^2 + \ldots}{+\, \beta_2''(A)^2 + \ldots + m(M)^{m-1}(\beta_1^{(m)}(A) + \beta_2^{(m)}(A)^2 \ldots} \qquad (4)$$

L'équation (4) a été obtenue en remplaçant, dans l'équation (1), C_A et C_M par leurs valeurs déduites de la relation (2) et, respectivement (3) ; les concentrations des différentes espèces ioniques ont été, de même, remplacées, par leurs expressions déterminées par la relation générale :

$$(M_m A_n) = \beta_n^{(m)} (M)^m (A)^n \qquad (5)$$

Lorsque dans la solution du sel d'uranyle il ne se forme que des complexes mononucléaires, les constantes β'', β''', … β^m … $= 0$ et — ainsi qu'on peut le constater de l'analyse de la relation (4) — $\overline{n}$ dépend seulement de (A) et ne dépend pas de (M).

Dans ce cas on obtient graphiquement, pour les différentes concentrations du C_M, des courbes $n = f(A)$, coïncidentes.

Lorsque dans le système il se forme aussi des complexes polynucléaires, les constantes β'', β''' … $\neq 0$, et $\overline{n}$ dépend tant de (A) que de (M), ce qui se traduit graphiquement par l'obtention des courbes $\overline{n}$ en fonction de (A), à de différentes valeurs du C_M, parallèles.

Compte tenu que les données déterminées expérimentalement ont été obtenues par la méthode pH-métrique et se rapportent au ligand « libre » $(A) = (\mathrm{OH}^-)$ d'une manière indirecte, la quantité mesurée directement étant la concentration des ions H^+, liée à (OH^-) par la relation : $(\mathrm{OH}^-) = K_w/(\mathrm{H}^+)$, l'expression mathématique de la fonction de formation devient :

$$\overline{n} = \frac{1}{(\mathrm{H}^+)} = \frac{\left(x_1' + \frac{2x_2'}{(\mathrm{H}^+)} + \frac{3x'}{(\mathrm{H}^+)^2} + \ldots\right) + (M)\left(x_1'' + \frac{2x_2''}{(H^+)} + \right.}{\left(1 + \frac{x_1'}{(\mathrm{H}^+)_{(m)}} + \frac{x_2'}{(\mathrm{H}^+)^2} + \ldots\right) + 2(\mathrm{M})\left(\frac{x_1''}{(\mathrm{H}^+)} + \frac{x_1''}{(\mathrm{H}^+)^2} + \right.}$$
$$\frac{\left. + \frac{3x_3''}{(\mathrm{H}^+)^2} + \ldots\right) + (M)^{(m-1)} \frac{p x_p}{(\mathrm{H}^+)^{p-1}} + \frac{(p+1)\, x_{p+1}^{(m)}}{(\mathrm{H}^+)^p} +}{+ \frac{x_3''}{(\mathrm{H}^+)^3} + \ldots + m(M)^{m-1} \frac{x_p^{(m)}}{(\mathrm{H}^+)^p} + \frac{x_{p+1}^{(m)}}{(\mathrm{H}^+)^{p+1}} +}$$
$$\frac{\left. + \frac{(p+2)\, x_{p+2}^{(m)}}{(\mathrm{H}^+)^{p+1}} + \ldots\right) + \ldots}{\left. + \frac{x_{p+2}^{(m)}}{(\mathrm{H}^+)^{p+2}} + \ldots\right) + \ldots} \qquad (6)$$

L'équation (6) a été obtenue en remplaçant, dans la relation (4), les valeurs de $A = (OH^-)$ par $K_w/(H^+)$ et en réunissant les constantes β et K_w dans de nouvelles constantes x, conformément à la relation :

$$(M_mA_n) = (M_m(OH)_n) = \beta_n^{(m)}(M)^m(OH^-)^n =$$

$$= \beta_n^{(m)} + K_w^n + \frac{(N)^m}{(H^+)^n} = x_n^{(m)} + \frac{(N)^m}{(H^+)^n} \tag{7}$$

Ainsi qu'on peut observer de l'équation (6), $\bar{n}$, le nombre moyen de ligands OH^- liés à l'ion central de UO_2^{2+}, dépend seulement de (H^+), si dans le système il ne se forme que des complexes mononucléaires ; $\bar{n}$ dépend tant de (H^+) que de (M), lorsque dans le système il se forme aussi des complexes polynucléaires.

Le calcul de la concentration des ions OH^- consommés pour la formation des complexes, à un moment donné du titrage, C_{OH}, a été fait compte tenu du fait que la quantité de NaOH qui correspond au premier point d'inflexion des courbes pH-métriques équivaut à la quantité d'acide présente dans la solution au moment initial.

En corrigeant, dans les calculs, la concentration des solutions en fonction du volume, $\bar{n}$ peut être déterminé à l'aide de la relation :

$$\bar{n} = \frac{C_{OH}}{C_M} \tag{8}$$

Les données expérimentales et les résultats obtenus par le calcul pour les solutions de perchlorate d'uranyle de différentes concentrations et forces ioniques sont présentés dans les tableaux 1–16.

La détermination de la nature des espèces ioniques formées par l'hydrolyse a été faite par l'analyse du diagramme 1.

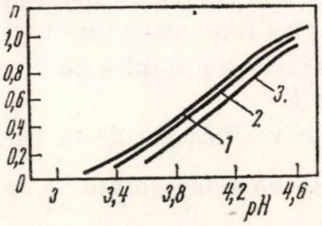

Fig. 1. — Courbes de formation déterminées pour les différentes concentrations des solutions de perchlorate d'uranyle, à I = 0,5.

C = 0,05 M (courbe *1*) ; C = 0,02 M (courbe *2*) ; C = 0,01 M (courbe *3*).

De l'analyse de la figure 1 on constate que les courbes $\overline{n} = f(\mathrm{pH})$ ne coïncident ni même pour les moindres valeurs de C_M ; on tire la conclusion que l'hydrolyse de l'ion UO_2^{2+} implique la formation des complexes polynucléaires, cette tendance se manifestant même à des dilutions très grandes.

La tendance de l'ion UO_2^{2+} de former, dans la solution, des complexes polynucléaires est analogue à celle de tous les métaux du groupe VI qui, en état d'ions hexavalents, apparaissent sous forme d'ions complexes avec de l'oxygène (CrO_4^{2-}), MoO_4^{2-} et WO_4^{2-}) et ont une tendance très marquée à l'agrégation.

2. L'ÉTUDE DU SYSTÈME PERCHLORATE D'URANYLE-EAU PAR LA MÉTHODE « CORE + LINKS »

Conformément à la méthode « core + links », considérée à présent, la méthode la plus efficace pour l'étude des complexes polynucléaires, la déduction de la nature et de la formule générale des espèces ioniques formées par l'hydrolyse est basée sur l'analyse des courbes $Z(\log h)_M$, analogues aux courbes $n(\log h)_M$, obtenues en représentant les valeurs de Z en fonction de $\log h$ et en réunissant tous les points qui se caractérisent par M constant.

(A mentionner que : Z représente le nombre moyen d'ions OH^- liés à l'ion central d'uranyle ; h = la concentration des ions d'hydrogène « libres » ; M = la concentration totale des ions UO_2^{2+} libres ou liés dans les complexes.)

Lorsque les courbes $Z(\log h)_M$ coïncident, dans le système il ne se forme que des complexes mononucléaires, caractérisés par la formule générale $Me(OH)_n$; si les courbes $Z(\log h)_M$, obtenues pour les différentes valeurs de M, sont parallèles, la distance entre elles, $\Delta\log h$, étant proportionnelle à $\Delta\log M$, on peut écrire la relation :

$$\left[\frac{\partial \log M}{\partial \log h}\right]_Z = -R = t = \text{constant}. \tag{9}$$

Dans le cas où la concentration des ions UO_2^{2+}, « libres » (m) est négligeable en comparaison de la concentration totale de l'ion $UO_2^{2+}(M)$, les complexes formés dans le système peuvent être considérés de type « core + links » et caractérisés par la formule générale $Me[(OH)_t Me]_n$, dans laquelle « t » est une constante déterminée graphiquement en utilisant la relation (9) et « n » représente une variable non déterminée.

Ainsi qu'il résulte de l'équation (9), Z est fonction de $X = \log M - t \log h$.

La vérification de la valeur déterminée graphiquement pour « t » a été faite en représentant $Y = \frac{Z}{t}$ en fonction de $X = \log M - t \log h$.

Dans le cas où « t » a été correctement calculé, on obtient, pour toutes les valeurs de M, une seule courbe $Y = f(X)$.

Après avoir établi la formule générale des complexes résultés de l'hydrolyse, il faut déterminer les valeurs de « n » et la nature des réactions qui ont lieu dans le système.

En considérant que, dans le système perchlorate d'uranyle-eau, il se forme des complexes « core + links », le type général de réaction qui doit être analysée est :

$$UO_2^{2+} + tnH_2O + nUO_2^{2+} \rightleftarrows UO_2[(OH)_tUO_2)]_n^{2+} + tn\ H^+$$

En ce qui concerne la valeur de « n », on obtient des indications en analysant l'allure des courbes $Y(X)$.

Du fait que les courbes $Z\ (\log h)_M$ obtenues pour les solutions aqueuses de perchlorate d'uranyle sont parallèles, on tire la conclusion que l'ion UO_2^{2+} hydrolyse avec la formation des ions complexes polynucléaires du type « core + links » caractérisés par la formule générale $UO_2\,[(OH)_t\,UO_2]_n^{2+}$.

La valeur de « t » $\left(t = -R = \frac{\log M}{\log h}\right)$ a été établie à l'aide du diagramme 2, qui représente $\log M = f(\log h)_{Z=\text{ct}}$.

Tel qu'on le voit dans la figure 2 les droites $\log M = f\ (\log h)_{Z=\text{ct}}$ sont parallèles et se caractérisent par une pente $\frac{\log M}{\log h} = 2$, ce qui mène à la conclusion que $t = -R = 2$, Z étant fonction de $X = \log M - 2 \log h$.

Pour confirmer la valeur $t = 2$, les données expérimentales ont été recalculées et représentées dans le système de coordonnées $Y = Z/2$, en fonction de X (fig. 3).

Ainsi qu'on le constate de la figure 3, les courbes $Y = f(X)$ obtenues pour deux solutions de perchlorate d'uranyle (0,033 M et 0,02 M) se superposent, ce qui confirme que $t = 2$ et les ions formés par l'hydrolyse se caractérisent par la formule générale : $UO_2[(OH)_2UO_2]_n^{2+}$.

En ce qui concerne le nombre des complexes qui résultent de l'hydrolyse on a obtenu des indications en analysant l'allure des courbes $Y(X)$.

Du fait que, dans le domaine de concentration et du pH étudié, la courbe qui représente la variation du nombre des ions OH^-/UO_2^{2+} croît continuellement à mesure que la valeur de X augmente, on peut déduire que, par l'hydrolyse de l'ion UO_2^{2+}, il se forme une série illimitée de complexes polynucléaires du type $UO_2[(OH)_2\ UO_2]_n^{2+}$.

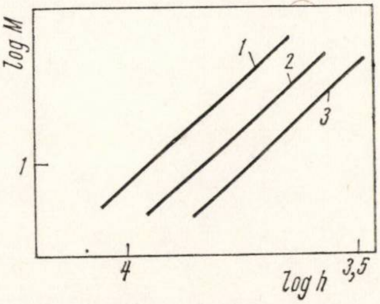

Fig. 2. — Détermination de la valeur « t » de la formule : $UO_2[(OH)_tUO_2]_n^{2+}$ ($Z=0,2(1)$; $0,3(2)$ et $0,4(3)$)

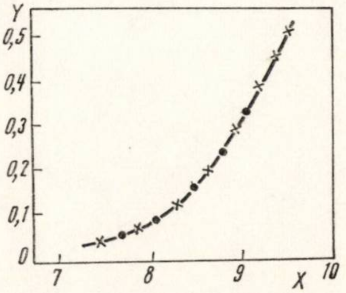

Fig. 3. — Vérification de la valeur « t » à l'aide de la courbe $Y = f(X)$.

CONCLUSIONS

L'application de la méthode de la « fonction de formation » et « core + links » à l'étude de l'hydrolyse de l'ion UO_2^{2+} en milieu perchlorique, tenant compte de toutes les espèces ioniques qui peuvent résulter de la réaction, a démontré que l'hydrolyse de l'uranium (VI) a lieu par une suite de réactions qui mènent, même dans le cas des solutions très diluées, à la formation d'une série illimitée de complexes polynucléaires du type $UO_2[(OH)_2\ UO_2]_n^{2+}$.

Ce comportement est analogue à celui de certains autres ions métalliques qui contiennent de l'oxygène et qui font partie du même groupe du système périodique : CrO_4^{2-}, MoO_4^{2-}, WO_4^{2-}.

THE ROLE OF CLINKER AND OF CALCIUM CHLORIDE IN THE HARDENING PROCESS OF SOME SILICATE SLAGS

I. TEOREANU and MARIA GEORGESCU

Polytechnic Institute
Laboratory of Technology of Silicates
and Oxide Compounds
Str. Polizu 1
Bucharest, Romania

Received October 25, 1972

The present paper studies the hardening processes of some silicate slags corresponding to wollastonite and rankinite and the manner in which they are influenced by adding Portland cement clinker and calcium chloride, single or together. Additions of 15 % Portland cement clinker, 2 % calcium chloride or 15 % clinker + 2 % calcium chloride, activate the hardening process of wollastonite and rankinite slags. The intensity of the activating effect varies with respect to the nature of the additions and to the basicity of the silicate slag. The mixed addition of 15 % Portland cement clinker + 2 % calcium chloride proved to be most efficient. The activating action of clinker or calcium chloride additions is manifested both by the intensification of the hydration processes of slags and by the increased crystallinity of the hydrated phases and, possibly, change of their basicity.

1. The reduced basicity of calcium silicates existing in high furnace slags accounts for the insignificant rate at which hydration processes are manifestly intensified by adding basic substances (introducing calcium hydroxide into the system), either calcium sulphate or calcium chloride — single or together.

The activating action of calcium hydroxide generating additions upon the hardening processes of calcium silicates in C_2S, C_3S_2, CS * slags is certainly ascertained; however, different opinions are expressed with regard to the nature of this action — as to whether the calcium hydroxide introduced into the system participates or not in the chemical reaction of hydrosilicates formation. Thus, while a number of researchers [1-4] consider that the role of $Ca(OH)_2$ is to provide a certain basicity of the medium, permitting thus a relatively high-speed formation of hydrosilicates which would condition the hardening of the system (without direct participating in the chemical formation process of those compounds), others [5] consider that the silicate slag, in the process of hydration, binds the calcium hydroxide resulting from basic additions. Smolczyk [6] relates the nature of calcium hydroxide action to the water/solid ratio of the system : in the case of β-C_2S pastes or mortars, calcium hydroxide introduced into the system by a basic addition, adheres to the silicate being hydrated, having, however, an indirect action in suspensions, since it influences the rate of the hydration processes without direct participating in them.

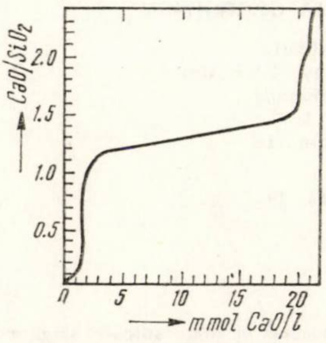

Fig. 1. — Dependence of CaO/SiO_2 ratio of the solid phase formed by hydration of calcium silicates on CaO concentration of the solution.

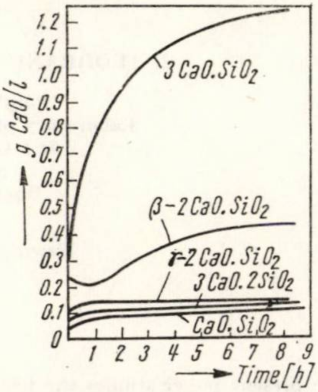

Fig. 2. — Variation of the CaO concentration in solution in the hydration of calcium silicates.

A unitary point of view may be reached in this sense, considering the equilibrium conditions that are being established in the calcium silicate — water system (figs. 1 and 2)

If the presence of the basic addition induces in the silicate — water system a higher CaO concentration than the equilibrium concentration, corresponding to the CaO/SiO_2 ratio of the hydrosilicate, formed by hydration of the silicate slag, it will bind calcium oxide in solution; in the opposite case, CaO will not be consumed in the hydration process or will be consumed only in small amounts.

2. Our present investigations concentrated on the effect of the Portland cement clinker and calcium chloride additions — single or together — upon the hydration of some silicate slags and the nature of hydrated phases formed under these conditions. Slags corresponding to rankinite ($3\,CaO.2SiO_2$) and wollastonite ($CaO.SiO_2$) * were synthesized to this end by melt-

* Bicalcium silicate, another constituent of furnace slags, has formed the object of numerous previous investigations.

ling stoichiometric mixtures of chemically pure oxides in an oxiacetylene flame and granulating in water.

Determinations of bound water (table 1) made according to the method described by Butt [7] and roentgenographic and derivatographic investigations made on paste with a 0.4 water/binder ratio, point out the fact that the higher basicity of the medium resulting from a 15% clinker addition significantly intensifies the hydration of wollastonite and rankinite, compared to clinker — free systems.

Table 1

Hydration degree of some silicate slags

Compound	Activating addition (%)		Amount of water bound in hydration (%) after :			
	Clinker	$CaCl_2$	28 days	90 days	180 days	360 days
$CaO \cdot SiO_2$	—	—	2.619	2.860	3.266	2.483
	—	2	3.128	4.080	5.576	6.903
	—	3.5	3.757	5.205	7.051	—
	—	5	4.125	8.311	7.981	7.408
	—	10	5.553	8.324	10.065	9.382
	—	20	7.715	11.065	12.080	17.220
	15	—	7.573	10.680	9.873	11.505
	15	2	10.576	12.360	11.937	13.336
$3CaO \cdot 2SiO_2$	—	—	2.930	6.290	7.281	11.574
	—	2	3.180	10.500	9.833	11.554
	15	—	11.500	11.800	9.980	10.614
	15	2	11.050	10.880	12.113	13.830

The increased hydration rate in the presence of an addition of 15% clinker, after 28 days could not be explained even if assuming the total hydration of the clinker (an unworkable phenomenon in fact), without also considering the acceleration of the hydration-hydrolysis processes of silicate slags in the presence of clinker.

Pure *wollastonite* does not form roentgenographically detectable hydrated phases, even after a period of 360 days. The endothermic effects appearing at temperature ranges of 150 . . . 220° and 600 . . .780° on the differential thermal analysis curves presented in figure 3, indicate the existence of certain amounts of hydro-compounds of the tobermorite hydrosilicates type.[8–10] Their preponderant gelic nature makes roentgenographic detection difficult.

It has been found that calcium hydrosilicates of CSH(I) type are formed in the presence of Portland cement clinker, even after short periods of time. They are revealed roentgenographically by interferences 3.03—3.05 (3.02)Å, 2.74—2.81 (2.78)Å and 1.79—1.82 (1.81)Å and thermographically by the endothermic effects from 140 ...150° and 660 . . . 750° (fig.4).

[10] Iu. M. Butt and L. N. Raschovich, "Hardening of binders at high temperatures", Ed. Tehnică, Bucharest, 1969 (translated from Russian).

All investigated wollastonite samples reveal the presence of an exothermic effect at temperatures of 840.. .850°. The higher amplitude of this effect for the anhydrous wollastonite or for wollastonite hydrated without additions causes us to assume that it is determined by the devitrification of the wollastonite slag.

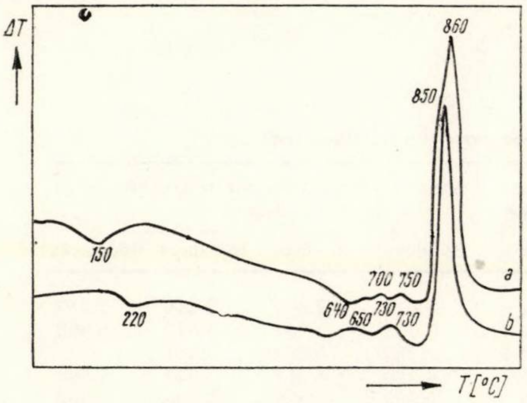

Fig. 3. — ATD curves of slag with a $CaO.SiO_2$ composition, hydrated for :
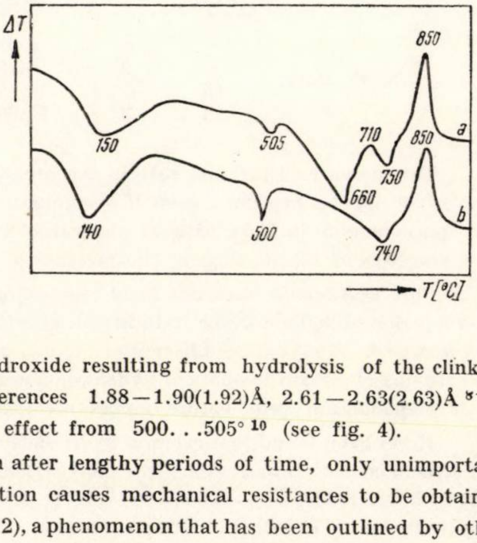
a — 90 days; b — 180 days.

Fig. 4. — ATD curves of slag with a $CaO.SiO_2$ composition, with 15% Portland cement clinker addition, hydrated for :
a, 90 days; b, 180 days.



The existence of the free calcium hydroxide resulting from hydrolysis of the clinker, is expressed roentgenographically by interferences 1.88 — 1.90(1.92)Å, 2.61 — 2.63(2.63)Å [8-10] and thermographically by the endothermic effect from 500. . .505° [10] (see fig. 4).

While pure wollastonite acquires, even after lengthy periods of time, only unimportant mechanical resistances, a 15% clinker addition causes mechanical resistances to be obtained as early as after 7 days of hardening (table 2), a phenomenon that has been outlined by other researchers as well. [11-13]

The mechanical resistances obtained must be attributed, in the first place, to the hardening of clinker and also to the activated slag. This statement is also supported by the fact, for instance, that mechanical resistance obtained for wollastonite and enstatite ($MgO.SiO_2$) [14]

7	10	10	45	100	90	21.6	43.5	53.5	67.8

* Mechanical resistances were determined on Kühl microsamples, manufactured of mortar with a 1 : 3 binder/aggregate ratio. They were calculated by relation : $R_c = F/S = F/2$ (daN/cm^2) ; $R_t = 6.F.l/a.b^2 = 60.F$ (daN/cm^2), where :

R_c – the compressive strength (daN/cm^2) ;
R_t – tensile strength (daN/cm^2) ;
F – breaking stress (daN) ;
S – cross-section area of the sample (cm^2) ;
l – length of the arm of the apparatus (cm) ;
a – width of the prism (cm) ;
b – thickness of the prism (cm).

with a similar clinker addition, has different values. In addition to this, significantly different mechanical resistances were obtained by replacing the slag in slag + clinker mortar by sand having a similar fineness (table 3).

Table 3

85	15	—	6.5	15.0	7.8	8.8
83	15	2	8.0	16.5	7.8	9.0
83	10	7	4.5	7.5	0	0
83	7	10	4.0	5.0	0	0

Calcium chloride does not exert an intensifying action upon wollastonite hydration (see table 1). The possible roentgenographic detection of some hydrated compounds of the tobermorite calcium hydrosilicates-type, even after 7 days of hydration, must be looked upon as a result of their more pronounced crystallization degree, compared to hydro-compounds formed by hydration of the pure wollastonite.

The fact that even in the case of big amounts of calcium chloride (up to 20 %), its binding and the formation of chlorinated complex combinations has not been reflected by roentgenographic and thermographic approaches, or by chemical analysis, makes us consider that

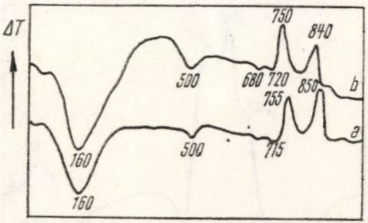
its action of intensifying wollastonite hydration (visible particularly after long periods of time) is a consequence of changes which it determines in the ionic equilibrium of the silicate-water system (especially from the viewpoint of its saturation),[15] withtout a direct participation in the chemical reactions involving the formation of hydrocompounds.

It is however possible to assume that chlorine ions introduced by calcium chloride are "built-in" in the calcium hydrosilicates lattice (this phenomenon was reported by Richartz[16] for the hydration of tricalcium silicate in the presence of calcium chloride) entailing consequences for morphology of the formed hydrosilicates. Such a phenomenon may induce the occurrence of an intense exotermic effect at 740...750° on the thermograms (fig. 5) owing to the displacement of the effect corresponding to tobermorite hydrosilicates towards lower temperatures.

Fig. 7. — ATD curves of slag with a $CaO.SiO_2$ composition, hydrated in the presence of 15% Portland cement clinker + 2% $CaCl_2$, for:
a, 90 days; *b*, 180 days.



At the same time, the electronomicroscopic images of wollastonite hydrated for 90 days in the presence of 2% $CaCl_2$ (fig.6) reveal the fibrous aspect of the hydrated phases (different from those noticed in pure wollastonite). This aspect is similar to that reported by other research workers[8,17,18] for stronger basic hydrosilicates, formed in chlorine-free systems.

The influence of calcium chloride on wollastonite hydration and hardening processes is however insignificant, particularly if we take into account the values of mechanical resistances obtained in the $CaO.SiO_2$ system ; we must consider, in the first place, the accelerating action exerted by calcium chloride on clinker hydration-hydrolysis processes, especially in short intervals of time, with consequences upon wollastonite hydration. The activating action of clinker on the hydration of monocalcium silicate is, in fact, intensified in this way. An important increase in the hydration rate is subsequently observed, materialized both by a higher amount of bound water after 28 days (see table 1) and by a significant reduction of the amount of nonhydrated wollastonite (as indicated by the amplitude of the devitrification effect from 840...850° — fig. 7) compared to the sample activated by the clinker alone (see fig.4). The endothermic effect from 500° — more reduced in amplitude as against the same effect on the thermograme, if wollastonite hydrated in the presence of clinker (see fig. 4) — ascertains the more intense hydration of monocalcium silicate, with $Ca(OH)_2$ binding under the conditions of a mixed addition of 15% clinker and 2% calcium chloride.

Tobermorite-type calcium hydrosilicates — CSH(I) — are identified as the main hydrated phases, in this case too. They have a more pronounced crystalline character reveling a higher number and intensity of roentgenographic interferences. Chlorinated complex combinations are not reported this time either. The strong exothermic effect from 750...755° (see fig. 7), ampler than for wollastonite hydrated in the presence of 2% $CaCl_2$ may be explained by the possible "built-in" of chlorine in the calcium hydrosilicates lattice.

[15] I. Teoreanu, Paper presented at the 36-th Congress of Chemical Engineering, Bucharest, 1970.

[16] W. Richartz, *Zement-Kalk-Gips*, **22**, 447 (1969).

[17] A. Van Bemst, *Silicates Industriels*, **22**, 213 (1957).

[18] P. I. Bojenov and G. F. Suvorova, *Tsement*, **8**, 23 (1957).

Owing to an increased hydration rate and to a certain proportion being established between gelic and crystalline hydrated formations, wollastonite with a 15 % clinker + 2 % $CaCl_2$ addition presents, after hardening, significantly higher mechanical resistances than in the case of another addition (see table 2).

By using mixed additions, in which the proportion of calcium chloride was higher (correspondingly reducing that of the clinker) we found that resistance-wise the optimum addition for the hardened binder consists of 15% clinker + 2% $CaCl_2$.

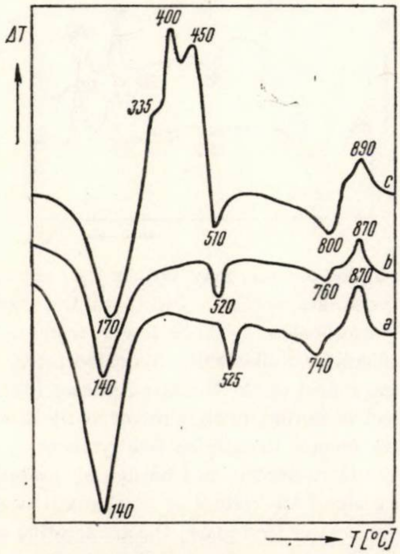

Fig. 8. — ATD curves of slag with a $3CaO.2SiO_2$ composition, hydrated in the presence of 15% Portland cement clinker, for :
a, 28 days ; *b*, 90 days ; *c*, 180 days.

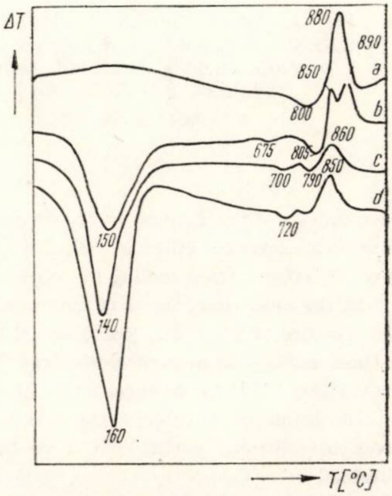

Fig. 9.— ATD curves of slag with a $3CaO.2SiO_2$ composition :
a, anhydrous ; *b*, hydrated for 28 days ; *c*, hydrated for 90 days ; *d*, hydrated for 180 days.

In the case of slags having the composition of *rankinite*, characterized by a stronger basicity than wollastonite and which, even in pure state hydrates more intensely than wollastonite, the intensity of the activating action of clinker and calcium chloride — single or together — undergoes some changes : if in the case of calcium chloride, the hardening processes of rankinite slag are intensified to a larger extent, addition of clinker or clinker + calcium chloride induces changes, particularly in the nature of the hydrated products being formed.

Pure rankinite forms by hydration, weakly basic tobermorite calcium hydrosilicates— CSH (I), as main products. The presence of a 15% clinker addition in the system determines also the formation of some more basic hydrosilicates. The diminution in time of the endothermic effect characterizing calcium hydroxide (fig. 8) and the occurrence on the debyegrame of some specific interferences — 1.99—2.03 (2.0)Å, 1.51—1.52 (1.56)Å ascertain the formation of some CSH(II)-type compounds too.

The amount of hydrated, mostly gelic formations is much larger in the presence of clinker in the system and significantly increases after 180 days, which explains the appearence on the thermogram of the exotermic effect group from 335...460°[19] (fig. 8), effects that are not reported for pure rankinite hydrated over a similar period of time (fig. 9).

---

[19] A. V. Volzhenskii, Iu. S. Burov, B. N. Vinogradov and K. V. Gladkih, "Betony i izdelia schlakovykh i zolinykh materialov", Izd. lit. po stroit., Moskva, 1969.

In the presence of calcium chloride, vitrous rankinite behaves more actively with respect to water than wollastonite. This is reflected both by the higher hydration rate – particularly in long periods of time (see table 1) – and by the higher values of mechanical resistances – particularly after periods of time involving more than 28 days (table 4).

Table 4

Mechanical resistances of slags with a $3CaO.2SiO_2$ composition

Activating addition (%)		Compressive strength (daN/cm^2), after :				Tensile strength (daN/cm^2), after :			
Clinker	$CaCl_2$	7 days	28 days	90 days	180 days	7 days	28 days	90 days	180 days
—	—	0	21	40	—	0	6.9	—	—
15	—	22.5	62.5	85	—	18.8	31.0	—	—
—	2	40.0	115.0	126.0	—	26.4	41.5	—	—

Since, for a period of 28 days, calcium chloride does not change the hydration rate of rankinite, the relatively high mechanical resistances, acquired after this interval, must be due especially to the intensification of the crystallization processes of the hydrated products. Roentgenographic and electronomicroscopic investigations confirm the change in the crystallinity of the hydration products of rankinite, in the presence of calcium chloride. The more crystalline character of the hydrated phases in samples of rankinite with calcium chlorite is evident if comparing the electronomicroscopic images of pure rankinite with those of rankinite with 2% calcium chloride addition (fig. 10).

In the case of rankinite with calcium chloride addition, the curves ATD (fig.11) outline the displacement of the exothermic effect characteristic for weakly basic hydrosilicates, towards lower temperatures (746...810°). The probable explanation is the same as in the case of wollastonite.

The results of the chemical analyses carried out on rankinite suspensions with a calcium chloride addition, and with a water/binder $=50$ ratio of 50, show that not even in the case of large addition of calcium chloride (up to 20%) do we find formations of chlorinated complex combinations.

The simultaneous presence of clinker and calcium chloride in the rankinite-water system provides it with a more active character due to the intensification of hydration-hydrolysis processes of the clinker by calcium chloride, in the first place, and also to the activated hardening of the slag.

The more improved behaviour of the hardening system of C_3S_2-(clinker + $CaCl_2$)-water, versus the C_3S_2-clinker-water system, is likely to be largely determined by the better crystallization of hydrated formations (reflected in increased intensitites of roentgen interferences) and in a lesser degree by larger amounts of hydrocompounds. The hydration rate increases significantly, with the formation of increased amounts of hydrocompounds (however, preponderantly gelic on the whole) only after longer periods of time (180 days). The group of exothermic effects from 350...490° (fig. 12) and the amount of bound water beyond this interval (see table 1) reflects this phenomenon.

The diminution in time of the exothermic effect from 505...530° indicate the intensification of rankinite hydration, with the binding of calcium hydroxide liberated by hydrolysis of

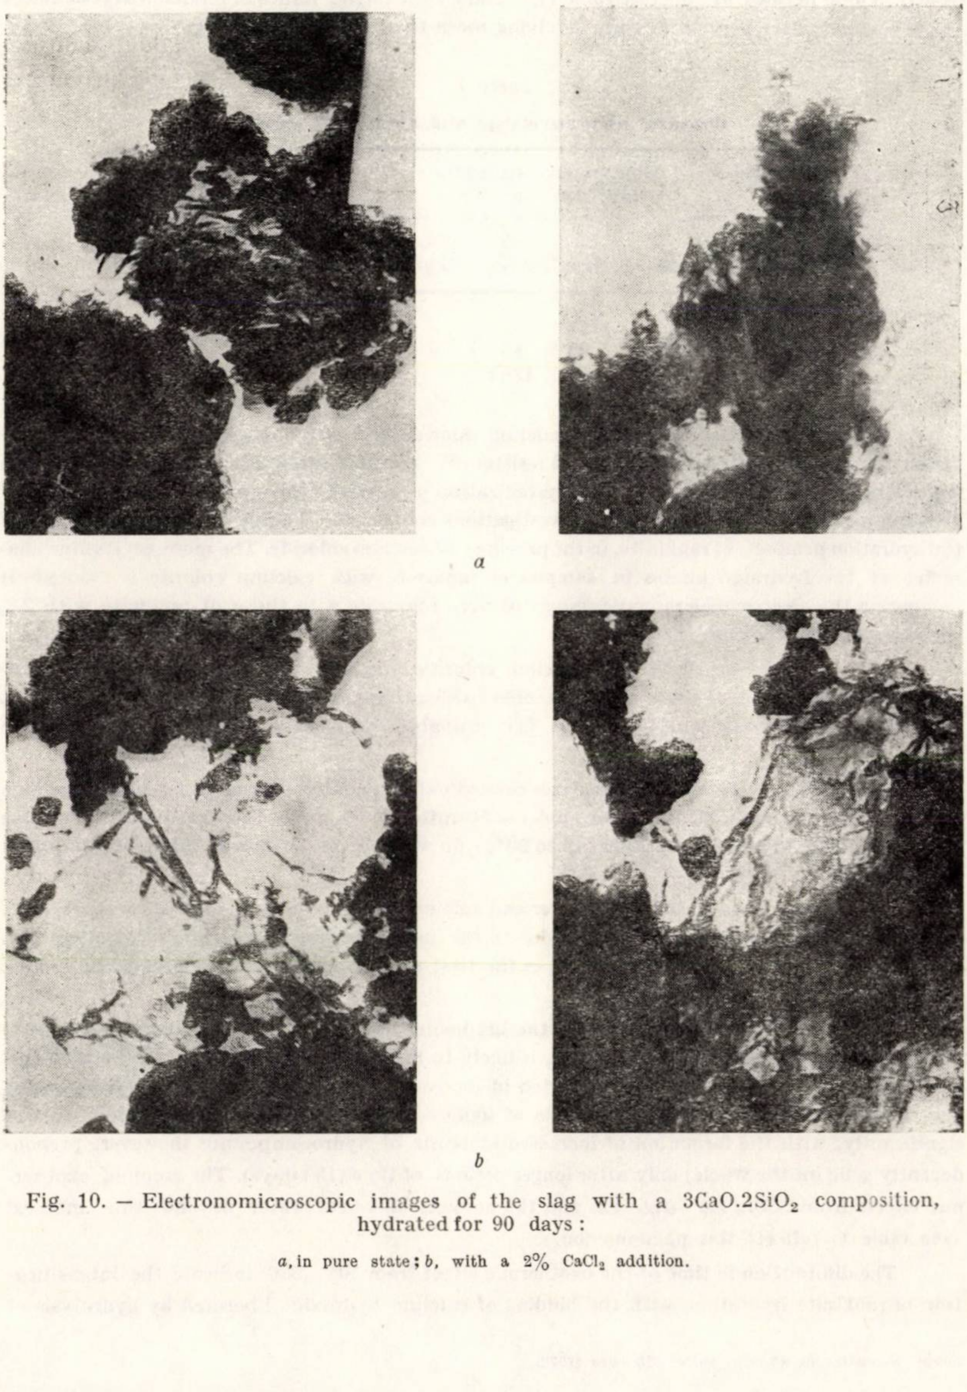

Fig. 10. — Electronomicroscopic images of the slag with a $3CaO.2SiO_2$ composition, hydrated for 90 days :

a, in pure state; *b*, with a 2% $CaCl_2$ addition.

the clinker. The reduced amplitude of this effect, compared to that of the similar effect on the thermogram of rankinite with an addition of clinker, must be considered as a confirmation of a more intense activation of rankinite by the mixed addition of clinker and calcium chloride.

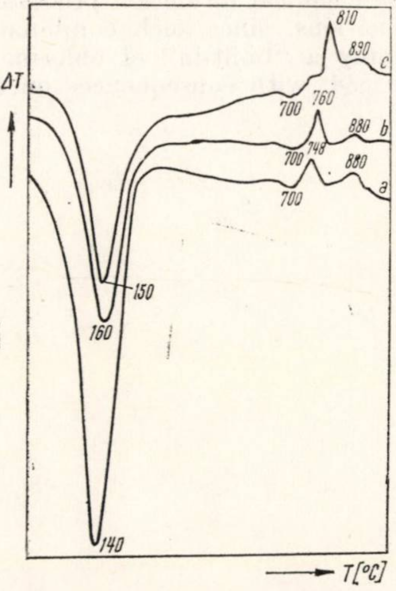

Fig. 11. — ATD curves of the slag with a $3CaO.2SiO_2$ composition, hydrated in the presence of 2 % $CaCl_2$, for : *a*, 28 days; *b*, 90 days; *c*, 180 days.

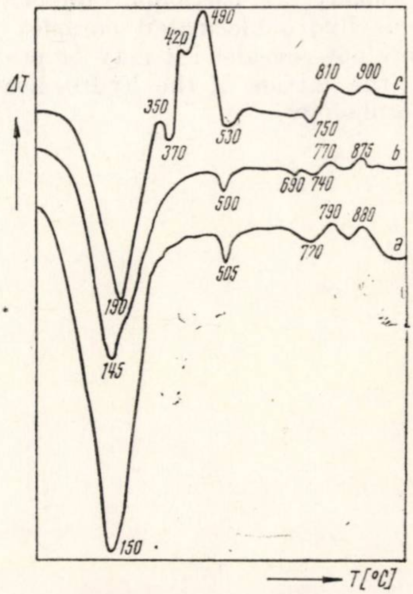

Fig. 12. — ATD curves of the slag with a $3CaO.2SiO_2$ composition, hydrated in the presence of 15 % Portland cement clinker + 2 % $CaCl_2$, for : *a*, 28 days; *b*, 90 days; *c*, 180 days.

3. Based on the results obtained with regard to the behaviour of calcium silicates in the presence of some activators, we may conclude that the action of additions used is manifested both by an intensified hydration rate of silicate slags and by an increased crystallinity of hydrated formations and the change of their basicity.

The existence of a parallelism between the behaviour of pure compounds and that in the presence of calcium chloride is also outlined.

The effect of calcium chloride varies in relation to the basicity of the silicates. By corroborating the present results with results obtained from other papers [15] we may say that, in the series of calcium silicates, the activating action of calcium chloride decreases in intensity in the following order :

$$3CaO.SiO_2 \rightarrow 2CaO.SiO_2 \rightarrow 3CaO.2SiO_2 \rightarrow CaO.SiO_2$$

Considering the fact that the reactivity of calcium silicates, even in pure state, increases as the basicity is increased, it may assumed that the intensified crystallization of the formed hydrated compounds is the prime determining element in the activation action of calcium chloride on those compounds.

With regard to the nature of the action of calcium chloride, it does obviously not participate directly in the chemical formation processes of some hydrochlorinated complex combinations, since such combinations were not revealed; it may be possible only a "built-in" of chlorine ion in the lattice of the hydrosilicates formed, with consequences on their morphology.

CHEMICAL GRAPHS. XVIII[1]

GRAPHS OF DEGREES FOUR OR LESS, ISOMERS OF ANNULENES, AND NOMENCLATURE OF BRIDGED POLYCYCLIC STRUCTURES

ALEXANDRU T. BALABAN

Institute of Atomic Physics, P. O. Box 35, Bucharest, Romania

Received November 23, 1972

Tables of graphs with degrees 2 — 4 and orders (number of points) 1 — 5 are presented and a recurrent procedure for the construction of such graphs is developed. The use of these tables is illustrated by a procedure for finding all possible isomers of annulenes, with explicit solutions for [4]-and [6]annulene: there are 217 possible graphs corresponding to formula C_6H_6, from which 58, including the five valence isomers $(CH)_6$, are not too unduly strained so as to preclude their existence as stable chemical compounds. Bridged polycyclic structures have topologies that are completely described by the same types of graphs, which could therefore find applications in coding and/or nomenclature. Several ways of improving the Baeyer system for the nomenclature of bridged polycyclics are briefly discussed. An exhaustive table of bi-, tri- and tetracyclic topologies is presented.

INTRODUCTION

In previous papers of this series, a recurrent procedure was presented for the construction of trivalent multigraphs (i.e. regular graphs where each point (vertex) has degree 3, i.e. is incident to three lines (edges), and two points may be joined by simple or multiple edges),[2] or trivalent general graphs (where a point may also be joined to itself by a loop which is counted twice in the degree). [3] Tables were presented, enumerating all possible trivalent multigraphs [2] or general graphs [3] with 10 points or less ; from larger graphs, only planar * multigraphs with 12 points were enumerated.[5]

---

[5] A. T. Balaban, *Rev. Roumaine Chim.*, **17**, 865 (1972).

The tables with all possible trivalent multigraphs are useful for an exhaustive search of valence isomers of annulenes since each point can be considered to represent a CH group, and each line one covalent bond. Tables of trivalent general graphs can, in addition, provide an exhaustive list of chemical structures which possess also divalent groups, such as valence isomers of 5- or 7-membered heterocyclic compounds; in this case a loop with the vertex to which it is attached is considered to represent the divalent group of atoms.[3]

Organic chemical structures can, however, possess quaternary carbon atoms which would correspond to points of degree 4 in the graph. In the project of devising an algorithm for the generation of all isomers corresponding to a given molecular formula, Lederberg [6,7] tried to avoid this complication by replacing vertices of degree four by vertices of degree three. This can be done either (i) by inserting an edge [6,7] resulting in the replacement of one vertex of degree four by two vertices of degree three or (ii) by replacing the vertex of degree four by the four intersections of lines emerging from this vertex with a small circuit around the vertex.[8] However, these procedures are not free from ambiguities, as indicated by figure 1 which proves that one and the same graph with a point of degree 4 can give rise to more than one trivalent graph in both procedures (i) and (ii).

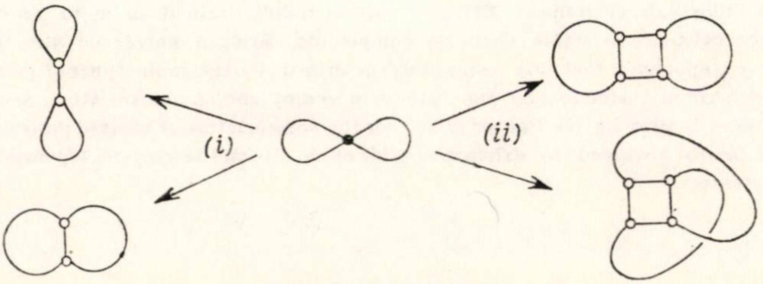

Fig. 1. — Replacement of a vertex of degree four in the unique graph of degree 4 and order 1 with two loaps by (i) two or (ii) four vertices of degree three.

In the present paper we will present a recurrent procedure for enumerating "head-on" [7] all given graphs with degrees equal to, or less than, four. Unlike previous cases, the degrees of the points will not be required to be all equal, i.e. the multigraphs will no longer be regular except where stated. It can be easily proved that in a graph the number of vertices with odd degree must be even.[4] All the following discussion will concern only connected graphs, i.e. graphs where any two vertices are connected by a path.

MULTIGRAPHS AND GENERAL GRAPHS OF DEGREE FOUR OR LESS

The construction of regular graphs of degree 3, including multigraphs and general graphs, was presented earlier.[2,3] Regular graphs of degree 2 are simple circuits with the required number of points. Graphs of degrees 3 and 2 (noted 3/2) and order p can be obtained from loop-graphs of degree 3 and order $p + 2k$ which do not have "geminal" loops, i.e. two loops bonded to the same point, by deleting the k loops and their lines of attachment. Alternatively, they can be obtained from trivalent graphs of order $p-1$ by inserting a point of degree 2 on each non-equivalent line.

The construction of regular graphs of degree 4 proceeds from the simplest circuit without any point, by intersecting it with itself and forming thus one point and the unique graph of degree 4 and order 1 with two loops. By repeating the procedure with this graph the intersection can be made within a loop or between the two loops, resulting in the two possible regular graphs of degree 4 with two points. The same process gradually builds or up all regular graphs of degree 4. Graphs of degrees 4/2 can be obtained from the latter by inserting a point of degree 2 on each non-equivalent edge or loop. Graphs of degrees 3/4 can be obtained from regular graphs of degree 4 by deleting one edge at a time, if it connected two vertices of degree four. Graphs of degree 4/3/2 are obtained from the last graphs by inserting points of degree 2 on each of their non-equivalent edges or loops.

Figure 2 presents the exhaustive list of connected multigraphs and general graphs with 1 through 5 vertices of degrees 2, 3 and/or 4. The numbers of these graphs are indicated in table 1 according to the parameters : total number of points p, number of loops λ, degrees, and partition of points according to their degree. As examples for points of degree 2,3 and 4, table 1 lists CH_2, CH and C groups, respectively ; in figure 2, black circles indicate points (vertices) of degree four and open circles of degree three ; no special symbol is used for vertices of degree 2. The outlay of figure 2 follows that of table 1. Excepting the complete graph K_5 with five points (5-clique)[4], all graphs presented here are planar, according to Kuratowsky's theorem ;[9] to emphasize their planarity, all planar graphs are drawn so that no line crosses.

By the procedure outlined above, figure 2 can be continued to orders $p > 5$ when necessary.

ISOMERS OF HYDROCARBONS

In their comprehensive search for the automation of inductive inference in organic chemistry, Lederberg and co-workers developed the DENDRAL program which can compute the isomers of acyclic organic compounds and match them against mass and NMR spectral data for struc-

tural identification with a minimal amount of manpower. [10] Cyclic structures, however, have not yet been included into this program.

Generally, for a structure formed from p_i atoms of valence $i (1 \leqslant i \leqslant 4)$ represented by a graph in which only vertices with $2 \leqslant i \leqslant 4$ are shown, the number q of edges is given by

$$2q = 4p_4 + 3p_3 + 2p_2 - p_1 \tag{1}$$

In the case of hydrocarbons with $p_4 = p$ carbon atoms and $p_1 = h$ hydrogens, represented by a graph showing only the C—C bonds, we have the number of edges according to (1),

$$q = (4p - h)/2 \tag{2}$$

The cyclomatic number μ of the graph indicates the number of its cycles, and for a connected graph is

$$\mu = q - p + 1 \tag{3}$$

Indeed, saturated alkanes, with $h = 2p + 2$, have according to (2) $q = p - 1$, hence $\mu = 0$. For hydrocarbons C_pH_h, by eliminating q between relationships (2) and (3), the number of cycles or double bonds is found to be

$$\mu = (2p - h + 2)/2 \tag{4}$$

Indeed, the same value results as half the difference between the number of hydrogens in an alkane with the same number of carbon atoms, $2p + 2$, and the actual number h of hydrogens.

Finding all isomers of a hydrocarbon is equivalent to finding all graphs according to partitions of $2q$ among the degrees of the points of the graph,[4] i.e. in the case of a hydrocarbon C_pH_h, partitioning $2q = 4p - h$ into p positive integers equal to, or smaller than, four. Alternatively, the h hydrogens must be partitioned into p non-negative integers equal to, or smaller than, three. These two partitions are in one-to-one correspondence since each of the pairs of p integers add up to four. The former partition gives smaller numbers for alkanes where $2q<h$; for cycloalkanes or monoolefins $2q = h$, hence the two groups of partitions are equal; for all other hydrocarbons, the latter partition is the simplest.

In such a case, the partitions of h into p non-negative integers 0, 1, 2, or 3, can be easily found from the table of partitions of h into at most p terms * by deleting all those partitions containing numbers greater than 3.

Having found all possible partitions of $2q$ or of h into p integers, one must then construct for each partition all possible graphs corresponding to that partition. Such graphs corresponding to one partition are *per definitionem* [2,3] valence isomeric structures.

ISOMERS OF ANNULENES

Annulenes C_pH_p have a long history with benzene, and a more recent one with cyclobutadiene, cyclooctatetraene, cyclodecapentaene, and the large annulenes which were intensely studied in the last years.[12] In order to obtain a complete list of all isomers ** of a given annulene, we divide the points of the graph corresponding to its structural formula according to their degrees $(C)_a\,(CH)_b\,(CH_2)_c\,(CH_3)_d$, and write the two balance equations for the carbon and hydrogen atoms, which must be solved in integers; a, b, c, and d are, respectively, number of points of degree 4, 3, 2 and 1 (points of degree one will be treated differently in the following).

$$a + b + c + d = b + 2c + 3d = p$$

By assigning to b various values $0 \leqslant b \leqslant p$, the second equation becomes a Diophantic one and can be easily solved in terms of integer c and d values. Then the first equation gives the value of a.

Alternatively, the following equivalences can be employed sequentially starting with $(CH)_p$ to yield all other isomeric partitions

$$(CH)_2 = C + (CH_2)$$

$$(CH)_3 = C_2 + (CH_3)$$

---

* The number of these partitions can be found in table 2 of ref. [11] or in references cited therein.

** Only topological (structural) factors are considered, geometrical or sterical isomerism is disregarded.

[11] A. T. Balaban, *Rev. Roumaine Chim.*, **17**, 9 (1972).

[12] F. Sondheimer, *Accounts Chem. Res.*, **5**, 81 (1972); *Pure Appl. Chem.*, **28**, 331 (1971).

For illustration the isomers of cyclobutadiene and of benzene are presented in figures 3 and 4, respectively. For C_4H_4 there are four classes of valence isomers, * corresponding to the four possible partitions of 4 into four non-negative integers smaller than, or equal to 3. There are 11 possible graphs corresponding to molecular formula C_4H_4, namely two valence isomers $(CH)_4$ i.e. cyclobutadiene and tetrahedrane which are cubic (trivalent) graphs of order 4, four isomers $C(CH)_2(CH_2)$, three isomers $C_2(CH_2)_2$ and two isomers $C_2(CH)(CH_3)$. These partitions of carbons and hydrogens result also by assigning integer non-negative values to variables k and j in the formula $(CH_3)_{1-k}(CH_2)_{2k-j}(CH)_{2j-k+1}(C)_{2-j}$.

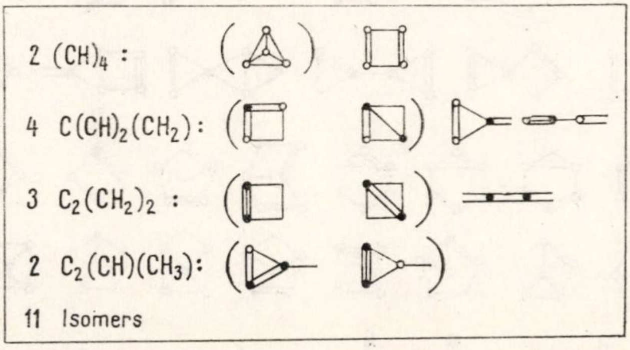

Fig. 3. — Isomers of C_4H_4.

All but the last group are to be found in the table of graphs of order 4 without loops. The last isomers with methyl groups corresponding to points of degree one will be treated differently, i.e. the methyl group will be considered together with the point to which it is attached; this point will accordingly have a degree lower by one and the whole graph an order lower by one if the methyl group is ignored. Hence the last group of isomers are found by attaching a point of degree 1 (a path of length one, i.e. a methyl group) to a point of degree 3 in graphs $C(CH)_2$, or to a point of degree 2 in graphs $C_2(CH_2)$. Alternatively, the last group (class) of isomers with methyl result from graphs $C_2(CH)_2$ with four vertices and one loop on a vertex of degree three, by replacing the loop with a methyl.

Owing to steric and electronic factors, only vinylacetylene and allene are stable compounds. Cyclobutadiene [13] and methylenecyclopropene [14-16] are unstable but have stable substituted derivatives : thus annelated naph-

thocyclobutadienes,[17] or cyclobutadienes with push-pull substituents[18a] or with steric effects[18b] are stable compounds; likewise, methylenecylopropene derivatives result from the condensation of cyclopropenones with active methylene groups.[19,20] Tetrahedrane is apparently an unstable reactive species.[21] The bicyclo[1.1.0]butenes might also be barely obtainable, whereas structures with acetylenic or allenic systems in 3- or 4-membered rings would be too strained to be obtainable.

There are 217 possible graphs corresponding to molecular formula C_6H_6. Partitions of carbons and hydrogens correspond to the following formula with non-negative integers k and j : $(CH_3)_{2-k}(CH_2)_{2k-j}(CH)_{2j-k}(C)_{4-j}$, i.e. to the seven classes of valence isomers corresponding to the partition of 6 into non-negative integers smaller than, or equal to, three : 6 valence isomers of benzene[2,5,22,23] the last of which is a chemically impossible non-planar graph, Kuratowsky's $K_{3,3}$, which are trivalent graphs of degree three, $(CH)_6$; 32 isomers of $C(CH)_4(CH_2)$, 76 of $C_2(CH)_2(CH_2)_2$ and 16 of $C_3(CH_2)_3$, which can be found by adding one point of degree 2 on each of, respectively, graphs $C(CH)_4$, $C_2(CH)_2(CH_2)$, and $C_3(CH_2)_2$ without loops, or on the loop of the same graphs with one loop.

The isomers with methyl groups are found as follows : the 7 isomers of $C_4(CH_3)_2$ are obtained by attaching two points of degree 1 to two points of degree 3 in graphs $C_2(CH)_2$ or to one point of degree 2 in graphs $C_3(CH_2)$; the 34 isomers of $C_2(CH)_3(CH_3)$ are obtained by attaching one point of degree 1 to one point of degree 2 in graphs $C_2(CH)_2(CH_2)$ or to one point of degree 3 in graphs $C(CH)_4$; and the 46 isomers of $C_3(CH)(CH_2)(CH_3)$ are found by attaching one point of degree 1 to a point of degree 2 of graphs $C_3(CH_2)_2$ or to one point of degree 3 of graphs $C_2(CH)_2(CH)_2$, or by attaching a path of length two (i.e. an ethyl group) to a point of degree 3 in graphs $C_2(CH)_2$ or to a point of degree 2 in graphs $C_3(CH_2)$.

Many of the structures presented in fig. 4 are too strained to be stable compounds (e. g. non-planar graphs, structures containing triple or cumulated double bonds in small rings, structures which do not obey Bredt's rule, derivatives of cyclobutadiene or tetrahedrane which are elusive molecules, or structures with all four valences of a carbon atom being coplanar or nearly coplanar);[24] the remaining 58 structures (all 15 acyclic ones in agreement with literature data,[25] fulvene, dimethylenecyclobutene, trimethylenecyclopropane, cyclopropenylallene, spirocompounds, etc.) should be obtainable and several of these are known. Isomerizations and valence isomerizations can occur : thermochemical and photochemical rearrangements of valence isomers of benzene $(CH)_6$ are known[2,5,12,23] and in addition to these, other thermal isomerizations are known, e.g. dimethylenecyclobutene, fulvene and benzene are formed on heating 1,5-hexadiyne to 300°.[26]

The number of isomers of C_pH_p increases exponentially with increasing p, but that of structures able to exist as stable compounds increases less rapidly. On the other hand, in hydrocarbons which are richer in hydrogen than annulenes, the difference between the number of possible isomers and of structures able of existence is smaller. Thus taking the C_5H_8 as an example, the possible 26 isomers which include isoprene, cyclopentene or pentyne are all strain-free and able of existence (fig. 5). For C_5H_8 there are six classes of valence isomers corresponding to the 6 partitions of 8 into at most 5 non-negative integers equal to, or smaller than, three : $3 + 3 + 2$, $3 + 3 + 1 + 1$, $3 + 2 + 2 + 1$, $2 + 2 + 2 + 2$, $3 + 2 + 1 + 1 + 1$, and $2 + 2 + 2 + 1 + 1$. They can be found as bicyclic structures (cf. next paragraph) from graphs without loops of figure 2, with degrees 3/2 or 4/2 and 3, 4 or 5 points possessing side-chains of 2, 1 or 0 carbon atoms, respectively ; with degree 3 and 2 points, possessing side-chains of 3 carbon atoms. These partitions correspond to formula $(CH_3)_{2-k}(CH_2)_{2k-j+1}(CH)_{2j-k}(C)_{2-j}$ with integer non-negative variables j and k.

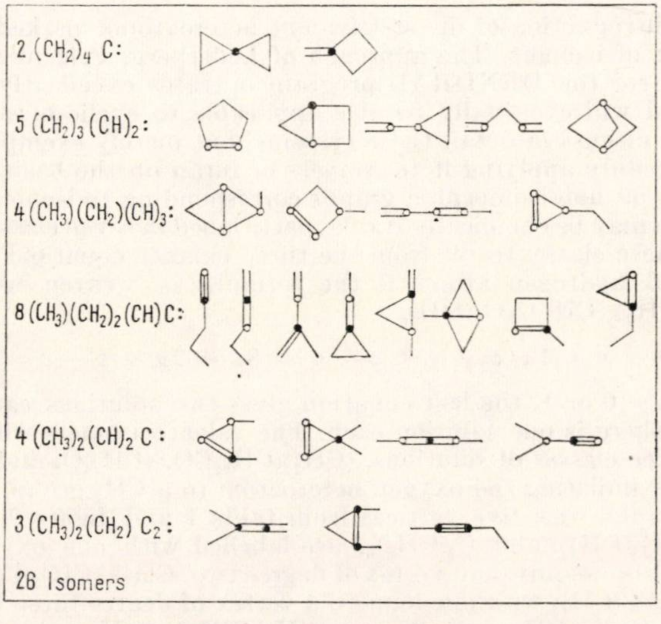

Fig. 5. — Isomers of C_5H_8.

Similarly, saturated alkanes[27a] C_nH_{2n+2} can be partitioned into classes according to formula $(CH_3)_{2+k}(CH_2)_{n-2k+j-2}(CH)_{k-2j}(C)_j$, with integers $0 \leqslant k \leqslant (2n-4)/3$ and $0 \leqslant j \leqslant (n-2)/3$: these classes correspond to partitioning $2q = 2p - 2$ into p positive integers $\leqslant 4$. Most of these are strain-free, hence stable molecules.

ISOMERS OF SYSTEMS WITH HETEROATOMS

The introduction of di- or trivalent heteroatoms markedly increases the number of isomers. The approach of Lederberg, Feigenbaum and coworkers[27b] *via* the DENDRAL program operates excellently for acyclic systems and will eventually be also applicable to cyclic ones. Therefore, we will not discuss in detail these systems, but merely exemplify the preceding procedure applying it to isomers of furan on the basis of figure 2. There exist 59 non-isomorphic graphs corresponding to isomers of C_4H_4O- (23 of which may be chemically stable) partitioned in seven classes of valence isomers. These classes result from the three balance equations for oxygen, carbon, and hydrogen atoms if the formula is written as $C_4H_4O \equiv \equiv (CH_3)_x(CH_2)_y(CH)_zC_wO_u(OH)_v$:

$$u + v = 1; \quad x + y + z + w = 3x + 2y + z + v = 4.$$

For $z = 0$ or 1, the last equation gives two solutions each, for $z =$ 2, 3, or 4, there is one solution each. The valence isomers within each of the last three classes of solutions, $(CH_2)(CH)_2CO$, $(CH)_4O$, and $(CH_2)_2C_2O$, result by assimilating the oxygen heteroatom to a CH_2 group. The corresponding graphs with five vertices from table 1 and figure 2, i.e. $C(CH)_2$-$(CH_2)_2$, $(CH)_4(CH)_2$, and $C_2(CH_2)_3$, are labelled with one oxygen heteroatom at each non-equivalent vertex of degree two. Class $(CH)_3\,C(OH)$ results from graphs $C(CH)_4$ with one loop on a vertex of degree three by replacing this loop with an OH group. Classes $(CH_2)\,(CH)\,C_2(OH)$ and $(CH_3)(CH)C_2O$ result similarly from graphs $C_2(CH)_2(CH_2)$ with one loop, by replacing the loop with an OH or a CH_3 group, respectively. Class $(CH_3)\,C_3(OH)$ results from graphs $C_2(CH)_3$ with two loops on vertices of degree three, by replacing them with one methyl and hydroxyl group. The resulting 59 isomers are presented in figure 6 ; the unstable chemical species are enclosed in brackets.

BRIDGED POLYCYCLIC COMPOUNDS

According to the IUPAC nomenclature rules[28] based on the Baeyer system[29] (also adopted by Chemical Abstracts and by the Ring Index[30]) a compound is termed "μ-cyclic" if it can be converted into an acyclic structure (a tree) by deleting μ bonds, suitably selected.[31]

[31] M. Frèrejaque, *Bull. Soc. Chim. France*, **6**, 1008 (1939).

According to this convention, tetrahedrane is a tricyclic compound, and cubane a pentacyclic one, at variance with the polyhedra they represent ; even in condensed or bridged bicyclic compounds, there are three possible circuits. This causes some confusion, [23] but strict adherence to the convention can overcome this difficulty.

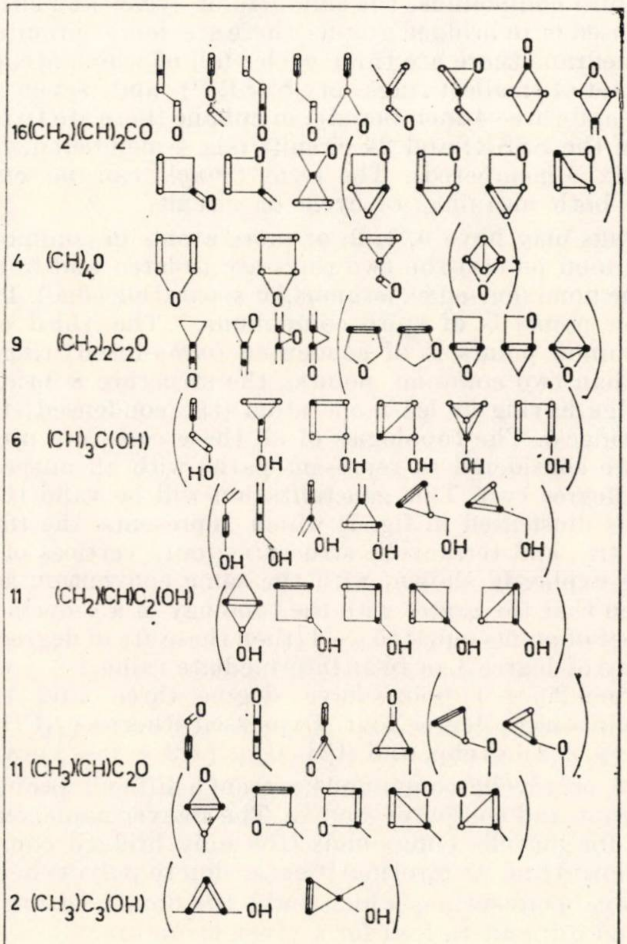

Fig. 6. — Isomers of C_4H_4O.

It is deemed advisable to maintain this convention since it is consistent with assimilating the number of cycles with the cyclomatic number μ (or nullity, or cycle rank) of a graph, $\mu = q - p + c$, where q, p and c are the numbers of edges, points and components of the graph. There have been several attempts to accomodate six rings in cubane, by defining fundamental [32] and real rings, [33] but they involve elaborate definitions and algorithms. One must take into account, however, that in condensed or bridged rings, deletion of one edge removes two circuits. Therefore, one should make a distinction between *cycles* (their number is given by the cyclomatic number) and *circuits* (which can include smaller cycles, but must not pass twice through the same edge or point). In separable graphs with isolated rings or in spiro compounds, the numbers of cycles and circuits are equal, but in condensed or in bridged graphs there are more circuits than cycles; e.g. in tetrahedrane there are three cycles (all of which are 3-membered in the smallest set of smallest rings or SSSR [34]) and seven circuits (four 3-membered and three 4-membered); in cubane there are five cycles (all 4-membered in the SSSR) and 24 circuits (six 4-membered, twelve 6-membered and six 8-membered). The term "*ring*" can be employed more loosely with both meanings of cycle or circuit.

Two rings may have 0, 1, 2, or more atoms in common. In the first case (no common points) the two rings are isolated and linked by a path of at least one bond (cut-edge, isthmus, or separating edge). The second case (one common point) is of spiro compounds. * The third case with two adjacent common points is of condensed (*ortho*-fused) rings. In the last case (more than two common points), the structure is bridged, with the shortest bridge having at least one atom (the condensed structures have zero-atom bridges). The topologies of all these cases are present in figure 2, if edges are considered to represent paths with an unspecified number of points of degree two. This generalization will be valid throughout this section and is illustrated in fig. 7, which represents the topologies of all possible bi-, tri-, and tetracyclic structures (only vertices of degrees three and four are explicitly shown, with the same convention as in figure 2). It can be seen that the graph with the topology of a μ-cyclic structure can have a number of points equal to $\mu-1$ (then these are of degree 4), to $2(\mu-1)$, when these are of degree 3, or to an intermediate value $\mu + j$ with $j = 0,1,2,.\ldots, \mu-3$, when $2(j + 1)$ points have degree three and the remaining $\mu - j - 2$ points have degree four. Expressed otherwise, $(CH)_p$ is $(p/2+1)$-cyclic, C_p is $(p + 1)$- cyclic, and $(CH)_xC_y$ is $(x/2 + j + 1)$-cyclic.

Bridged polycyclic compounds present a difficult problem for nomenclature, notation and computer storage. The Baeyer nomenclature system[29] was devised for bicyclic compounds (the only bridged compounds which were then known) and its informal [35] extension to polycyclic systems introduces additional conventions which make the nomenclature cumbersome redundant and difficult to find for a given structure.

Cumbersome: for more than three bridged rings, the Baeyer system name becomes very long. Therefore, trivial names are coined for such structures, e.g. for the newly discovered valence isomers of annulenes. In fact long systematic names are even funny.[36] Considerable confusion exists when trivial and semisystematic names coexist, as for example in the case of pentacyclo[$4.4.0.0^{2,5}.0^{3,8}.0^{4,7}$]dec-9-ene.[37,38] It was first synthetized by Masamune *et al.*[39] who gave it the trivial name "basketene" (and an erroneous Baeyer system name), and it was named by other workers 1,2-teheno-1, 2-secocubane[40] (but the structure was different because of an unexpected silver-ion catalyst effect).

---

* Larger spiro rings may have two or more common points, but these are not adjacent.

[32] R. Fugmann, U. Dolling and H. Nickelsen, *Angew. Chem.*, **79**, 802 (1967); *Angew. Chem. Internat. Edit.* **6**, 733 (1967).

[33] E. J. Corey and W. T. Wipke, *Science*, **166**, 178 (1969).

[34] M. Plotkin, *J. Chem. Docum.* **11**, 60 (1971).

[35] J. Meinwald and J. K. Crandall, *J. Amer. Chem. Soc.*, **88**, 1292 and especially pag. 1300 (1669).

Redundant : two informations are given twice each in the Baeyer name : the number of cycles (both as the prefix "μ-cyclo", and as the number of dots in the bracket, separting the numbers of atoms indicating the bridges) and the total number of atoms (both as a Greek numeral following the bracket, and as the sum of all bridge atom numbers within the brackets, plus two for the main bridgehead atoms).

Difficult : finding the corrected systematic name for a given structure is a tedious job, even for tricyclic structures ; for more than three bridged cycles, either a computer program must be employed,[41] or a long systematic approach must be followed.[38] There are many examples of incorrect names assigned to newly discovered bridged structures. Only two of these will be mentioned, namely (i) the tricyclo [$2.1.0.0^{2,5}$] pentane skeleton[35] to which *three incorrect* names were given by all three groups having prepared it (in turn, this has led to the failure of recognizing that one and the same structure had been obtained, which is irritating because chemistry is the best documented science), and (ii) the longer list given by Conrow[41] for erroneous and corrected * names.

At the same time, it must be recognized that the correct Baeyer system names are widely used, are unambiguous and allow an easy conversion into structural formulas.

In describing the computer program for generating correct Baeyer system names of bridged structures, Conrow[41] considered bi- to tetracyclic bridged structures. In figure 3 of his paper, Conrow lists the possible tricyclic and tetracyclic skeletons. These are in fact all cubic multigraphs without loops with 4 and 6 points, respectively (with the observation that Conrow's strucures *b* and *c* are isomorphic, therefore one of them should be deleted, and that the non-planar $K_{3,3}$ graph should be added to the list to make it complete).

The present list (fig.6) is complete because it contains also quaternary ring atoms (points of degree four). Together with the other lists of multigraphs without loops,[2,3] it could be used for expanding Conrow's program.

---

* One of the corrected names has a typographical error ;[41] instead of tetracyclo [$4.4.0.0^{2,4}.0^{3,6}$] decane one should read : tetracyclo[$4.4.0.0^{2,4}.0^{3,7}$]decane.

Fig. 7 (continued).

The present list (fig. 7) is also more comprehensive than the set of tricyclic graphs of degrees 3 and 4 presented in their figure 2 by Whitlock and Siefken. [42] * That set of ten graphs is essentially the list of cubic graphs with four points, of graphs with degrees 3/4 with three points, and of graphs with degree four with two points. If the two cubic graphs which are missing (one with two loops, the second with three loops) are added, the set becomes complete.

These two applications of the table 2 (of general graphs with points of degree four or less) illustrated the fact that the topologies of all possible polycyclic structures are mapped by these graphs. This could serve in the nomenclature of polycyclic structures by relating every structure to the topologically equivalent graph, and by denoting the topology with a symbol characteristic for the graph. In previous papers of this series, graphs were characterized by a symbol consisting in a string of non-negative integers indicating, in order, the numbers of points (the order p of the graph),** of loops λ, of double bonds (circuits with two points) β, of triangles t, and quadrangles q (circuits with 3 and 4 points, respectively) followed by a serial number, s. [2,3,5] Since as far as the numbers of hydrogens in isomers (where an edge of the graph symbolizes one covalent chemical bond), and of cycles in topologies of polycyclics are concerned (where an edge of the graph symbolizes a chain of atoms with one or more covalent bonds), a triple bond is equivalent to two double bonds, in notations of graphs this equivalence will be adopted in the notations of figure 7. Conventionally, when the graph is not regular, the numbers p_i of points of lower degree i will appear before those of higher degree; the respective degrees appear as lower indices of the numbers of points. A circuit is defined by its vertices rather than its lines; therefore, in a cyclopropenyl or a hypothetical cyclopropargyl group there is one 3-circuit not two or three 3-circuits. However, in tetrahedrane there are four 3-circuits and three 4-circuits, although it is considered as a tricyclic structure. Thus the notation consists of the symbols $p_i p'_{i'} p''_{i''}$-λ-β-t-q-s; this gives the possibility of arranging all graphs in figure 7 according to the increasing numerical order of all numbers (including lower indices) contained in their symbols. The serial number s is always 1 unless there is more than one graph with the same values for all other numbers in the symbol, when the serial number is assigned conventionally integer values starting with 1.

All these conventions are illustrated in figure 7 which presents all possible topologies of polycyclic structures with 2 to 4 cycles consisting of atoms with valence four or less. The topology is thus uniquely reflected in the symbol of the respective graph, which could be used for nomenclature and retrieval of this topology.

Some of the graphs from figure 7 have trivial names in graph theory; [43] 2_3-0-2-0-0-1 is the theta-graph; $2_3 1_4$ -0-2-1-0-1 is the gamma graph; 2_4-0-3-0-0-1 is the delta graph; 4_3-0-0-4-3-1 is the alpha graph; and 4_3-0-2-0-

---

* Cf. footnote [4] of that paper [42] for another critical remark concerning the Baeyer nomenclature system.

** Using subscripts for degrees, one should indicate the number of points of each degree.

[43] J. W. Essam and M. E. Fisher, *Rev. Mod. Phys*, **42**, Suppl., 271 (1970).

-1-1 is the beta graph. These are all the graphs without loops with cyclomatic numbers μ equal to two or three.

A previous list of graphs classified according to their cyclomatic number was compiled by Foster for electrical circuits.[44] The aim was different, therefore that list is at the same time more comprehensive (including also disconnected graphs and vertices of any degree) and less comprehensive (excluding loop-graphs and omitting some of the other graphs).

Alternatively, another approach might be used, namely a completely new proposal for the nomenclature of bridged systems. One such possibility rests on the facts that trees may be coded unambiguously starting from their centre [45,46] * or from their centroid [25,47] ** (both of these may be either one point, or two adjacent points [4,48,49]), and that μ cuts in a μ-cyclic bridged structure convert it into a tree. One could propose a convention for an unambiguous selection of cuts in order to convert a graph into a tree, e.g. the shortest bridges should be cut in order next to a bridgehead atom to lead to the longest non-branched chain); the μ cycles would result from specifying μ connections between pairs of points in the tree. One can take advantage of the existence of algorithms for finding the smallest set of smallest rings in a graph, [34] whose number equals the cyclomatic number of the graph, in these conventions for cuts.

---

* The centre of a tree [4,43] consists in the point(s) of minimum eccentricity, i.e. yielding minimal longest paths to any endpoint of the tree.

** The centroid or mass centre of a tree [4,43] (which may or may not coincide with its centre) consists in the point(s) of minimum weight, i.e. yielding the smallest maximum number of lines in any branch starting from it (them).

MATRIZIELLE CHARAKTERISIERUNG DER STRUKTUR UND TOPOLOGIE DER ORGANISCHEN VERBINDUNGEN. III[1,2]

KONFORMATION, CHIRALE KONFORMEREN

FRANCISC KEREK und IOAN MOȚOC

Organisch-chemisches Laboratorium des Polytechnischen Instituts „Traian Vuia",
Postfach 103 Timişoara, Romania

Eingegangen am 13. Oktober 1972

Es wurde eine matrizielle Ausdrucksweise der topologischen Beziehungen der chiralen Konformeren angestrebt. Zuerst werden die einfacheren Fälle der axialen Chiralität behandelt und nachher jene Fälle, in denen die die Achse bestimmenden Atome oder die von ihnen abzweigenden Liganden chiral sind. Die analytische Form des Chiralitätsoperatoren wurde sowohl für den allgemeinen Fall als auch für Sonderfälle abgeleitet.

1. EINLEITUNG

In den vorhergehenden Arbeiten [1,2] wurde eine matrizielle Charakterisierung der Konstitution und der Konfiguration der organischen Verbindungen, sowie der mit der zentralen Chiralität der Molekülarten zusammenhängenden Beziehungen versucht. So wie das in der zweiten Arbeit[2] klargelegt wurde, haben wir uns in erster Reihe mit den topologischen Aspekten der behandelten Probleme beschäftigt, wobei wir die Betrachtungen, soweit es möglich war, auf jene Strukturelemente beschränkten, die eine wesentliche Rolle in der Festlegung des Chiralitätssinnes einer sterischen Formation haben, was auch für die folgenden Diskussionen gültig bleibt.

2. AXIALE CHIRALITÄT, KONFORMATION

Die Existenz der axialen Chiralität setzt bidimensionelle Unterscheidungen bezüglich einer internuklearn Achse [3] voraus. Der Chiralitätssinn

---

[1] F. Kerek und I. Moțoc *Rev. Roumaine Chim.* **18**, 285 (1973).

[2] I. Moțoc und F. Kerek, *Rev. Roumaine Chim.* **18**, 291 (1973).

[3] R. S. Cahn, C. K. Ingold und V. Prelog, *Angew. Chem.*, **78**, 413 (1968).

kann auch konfigurativ spezifiziert werden, es ist aber angebrachter, dies konformativ zu tun, wobei die Bezeichnungen (+); P oder (−); M verwendet werden.

Um eine allgemein gültige Behandlung zu erreichen, die von den Kriterien zur Unterscheidung der konfigurativen und konformativen Aspekte der Molekülstruktur [4,5,6] unabhängig ist, werden in dieser Arbeit alle Fälle der axialen Chiralität einheitlich als konformative behandelt.[*]

2.1. DIE MATRIZIELLE CHARAKTERISIERUNG DER MOLEKULAREN KONFORMATIONEN

Indem wir die Bezeichnungen der vorhergehenden Arbeit [2] beibehalten, erhalten die Liganden die von den Achsenenden abzweigen die Symbole ψ_i, wobei $1 \leqslant i \leqslant n$; $(n = 2, \ldots, 8)$.[**]

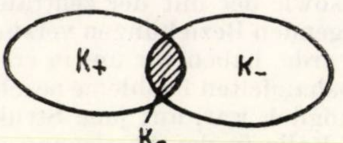
Es ist gleichfalls bekannt, daß die Liganden mit Hilfe der dem Liganden ψ_i zugeordneten Matrix matriziell beschrieben werden können.

Im Einklang mit der Cahn-Ingold-Prelog-Konvention [3,4] kann der Sinn einer axialen Chiralität eindeutig durch die relative räumliche Anordnung zweier Bezugsliganden ψ_α und ψ_β (je ein Ligand von jedem Achsenende) festgelegt werden. Die Bezugsliganden werden ihrerseits nach einfachen, allgemein anwendbaren Kriterien gewählt. Im Einklang mit den in den vorhergehenden Arbeiten veröffentlichten Ideen, können diese Bezugsliganden mit Hilfe der Matrizen M_α und M_β beschrieben werden.

Die Liganden ψ_i können unendlich viele räumliche Anordnungen in Bezug auf eine Torsionsachse einnehmen. Mathematisch ausgedrückt lautet dies wie folgt:

Die möglichen Konformationen in Bezug auf eine Torsionsachse bilden eine unendliche, unzählbare Menge K. Die Menge K kann in Abhängigkeit von dem axialen Chiralitätssinn in zwei Untermengen K_+ und K_- geteilt werden:

$$\begin{aligned} K_+ \cup K_- &= K \\ K_+ \cap K_- &= K_0 \end{aligned} \tag{1}$$



wo mit K_0 die Menge der achiralen Konformere bezeichnet wurde.

---

[*] Die Konformationen sind gemäß[3] die verschiedenen Varianten der räumlichen Anordnung der Atome im Molekülraum, welche Varianten sich eine von der anderen durch die Torsionsbewegung um eine internukleare Bindungsgerade unterscheiden.

[**] Bei Wasserstoffperoxyd $n = 2$, bei H_2N-OH $n = 3$, bei Äthylen $n = 4$, bei HC_3-CHO $n = 5$, bei Äthanabkömmlingen $n = 6$, bei organischen Phosphorverbindungen sind auch Fälle mit $n = 7$ oder $n = 8$ möglich.

[4] IUPAC Tentative Rules for the Nomenclature of Organic Chemistry Section E. Fundamental Stereochemistry; *J. Org. Chem.*, **35**, 2849 (1970).

[5] * * *, *Nachr. Chem. Techn.*, **17**, 443 (1969).

[6] G. Ostrogovich und F. Kerek (noch unveröffentlicht).

Einige Elemente der Menge K, d.h. besondere Konformationen, zeichnen sich durch Symmetrieeigenschaften oder durch die Inflexionspunkte in dem Enthalpiegehalt/Torsionswinkel (τ) - Diagramm aus. Die Abbildung 1 widerspiegelt solche Konformationen, die nach der relativen Anordnung der Bezugsliganden (ψ_α und ψ_β) bezeichnet wurden.

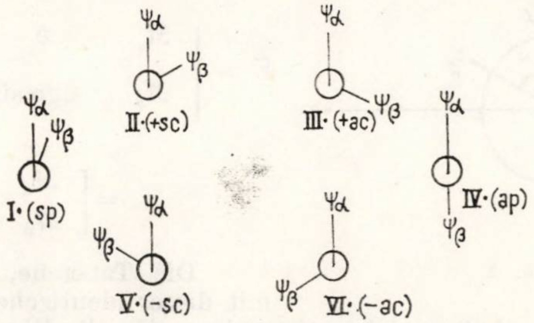


Abb. 1

Es kann leicht festgestellt werden, daß folgende Beziehungen wahr sind :

$$\text{II, III} \in \mathrm{K}_+ ; \quad \text{V, VI} \in K_- ; \quad \text{I, IV} \in K_0$$

Für den „Chiralitätssinn" spielt der Zahlenwert des Torsionwinkels τ eine zweitrangige Bedeutung. Also ist der Chiralitätssinn ein und derselbe für alle Werte* von τ die größer als Null und kleiner als π sind, d.h. + (Plus).

Genauso definieren negative Werte des Torsionwinkels einen negativen Sinn der axialen Chiralität, unabhängig von dem Zahlenwert von τ.

Für die topologische Charakterisierung der räumlichen Anordnung in Bezug auf eine Achse werden die Matrizen V' verwendet, die man von dem allgemeinen Matrizentyp V ableitet :

$$V = \begin{bmatrix} M_\alpha & 0 \\ M_\beta & \text{sign} \ \sin \tau \end{bmatrix} \qquad (2)$$

wobei M_α und M_β die konfigurativen Matrizen der Bezugsliganden ψ_α beziehungsweise ψ_β sind.

Das Element Null (0) aus der Stellung (12) zeigt übereinkunftsgemäß an, daß das Element aus derselben Reihe, d.h. ψ_α den dem Beobachter nahegelegenen Liganden darstellt.

---

* Bekanntlich spricht man von dem positiven Sinn, wenn der von dem Torsionswinkel zwischen ψ_α und ψ_β bestimmte Schraubsinn (vom Beobachter aus) nach rechts ist ; im Gegenfall handelt es sich um den negativen Sinn. Der Winkel τ wird hier im trigonometrischen Sinn betrachtet so daß sign sin τ den den Konformationen zugeordneten + oder – Zeichen entpricht.

Das Element aus der Stellung (22), d.h. sign sinτ legt den Sinn der Chiralität fest, wobei τ der von ψ_α und ψ_β gebildete Torsionswinkel ist.

Für den konkreten Fall des Beispiels, das in Abb. 1 mit II bezeichnet wurde, hat die Matrix V' folgende Form, die mit V'_{II} bezeichnet wird:

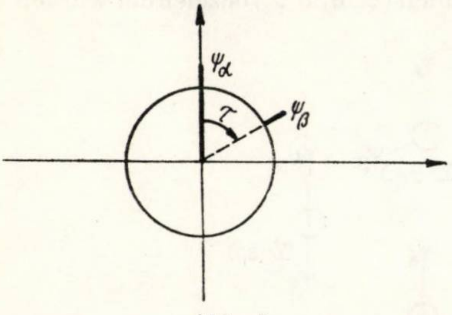

Abb. 2

$$V = \begin{bmatrix} \mathbf{M}_\alpha & 0 \\ M_\beta & \text{sign}\sin\dfrac{\pi}{3} \end{bmatrix} = V'_{\mathrm{II}} = \begin{bmatrix} M_\alpha & 0 \\ M_\beta & + \end{bmatrix} \tag{3}$$

Die Tatsache, daß man eine mit dieser identische Matrix V' auch für den Fall III erhält und im allgemeinen, für alle Werte $0° < \tau < \pi$ des Moleküls aus Abb. 1, weist auf die topologische Gleichwertigkeit dieser räumlichen Anordnung was ihren Chiralitätssinn anbelangt hin.

Für die achiralen Fälle I und IV aus Abb. 1 wird die konformationelle Matrix V' die Form V'_{I}, bzw V'_{IV} haben:

$$V'_{\mathrm{I}} = \begin{bmatrix} M_\alpha & 0 \\ M_\beta & \text{sign}\sin 0° \end{bmatrix} = V'_{\mathrm{IV}} = \begin{bmatrix} M_\alpha & 0 \\ M_\beta & \text{sign}\sin\pi \end{bmatrix} = \begin{bmatrix} M_\alpha & 0 \\ M_\beta & 0 \end{bmatrix} \tag{4}$$

Für den Zweck einer möglichst volkommenen matriziellen Beschreibung ist es notwending neben (i) *rein konformationellen Informationen* auch Daten bezüglich der:
(ii) *Konstitution und Konfiguration der Liganden* die von der betreffenden Achse abzweigen und
(iii) *der Konfiguration der die Achse bestimmenden Atome* miteinzuschließen.

Den Beobachtungen aus den vorhergehenden Arbeiten gemäß [1,2], wird die Konfiguration und damit auch die Konstitution durch Matrizen vom Typ M_i ($i = 1, \ldots, n$) wiedergegeben.

In dem Falle aus Abb. 3, in welcher $\psi_1, \ldots, \psi_6$ die Liganden sind, die von den die Achse bestimmenden Atome X und Y abzweigen, wird die Konfiguration des Atoms X bzw Y durch die Matrizen M_X bzw M_Y beschrieben, in deren Aufbau (siehe Beziehung 5) die den Liganden $\psi_1, \ldots, \psi_6$ entsprechenden Matrizen $M_1, \ldots, M_6$ eingegliedert sind.

$$M_X = \begin{bmatrix} M_1 & M_2 \\ \psi_Y & M_3 \end{bmatrix}; \quad M_Y = \begin{bmatrix} M_4 & \psi_X \\ M_5 & M_6 \end{bmatrix} \tag{5}$$

wobei ψ_Y (siehe Abb. 3) die Matrix 2×2 des Molekülteils darstellt, der an das Atom X durch das Atom Y angegliedert ist.

Genauso stellt ψ_X die Matrix des anderen Molekülteils dar, der durch das Atom Y an des Atom X gebunden ist.

Dies kann matriziell durch folgende Beziehungen ausgedrückt werden :

$$\psi_Y = M_Y = \begin{bmatrix} 0 & \psi_X \\ 0 & 0 \end{bmatrix} \tag{6}$$

$$\psi_X = M_X = \begin{bmatrix} 0 & 0 \\ \psi_X & 0 \end{bmatrix} \tag{7}$$

Vom Standpunkt des Moleküls als Gesamtheit können die Daten bezüglich der Konfiguration (und somit auch der Konstitution) der Liganden, sowie auch der der Atome vom Ende der Bezugsachsen in einer Matrix 2×1 gemäß der Beziehung (8)

$$W = \begin{bmatrix} M_X \\ M_Y \end{bmatrix} \tag{8}$$

zusammengefaßt werden.

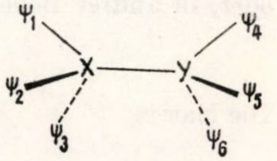

Abb. 3

Folglich wurden Matrizen folgenden Typs definiert :

1° V, die die Konformation der betreffenden Achse topologisch charakterisieren (i)

2° W, die die Konfiguration der Liganden, die von der Achse abzweigen matriziell beschreibt, einschließlich die Konfiguration der die Achse bestimmenden Atome.

Für das gleichzeitige Umfassen der durch W und V ausgedrückten Aspekte ist es angebracht, eine Matrix $\mathcal{W}$ zu verwenden, die wie folgt aufgebaut wird :

$$\mathcal{W} = \begin{bmatrix} W \\ V \end{bmatrix} \tag{9}$$

In dem nun Folgenden wird die Möglichkeit, die verschiedenen Beziehungen der konformativen Isomerie matriziell auszudrücken untersucht

Zuerst werden die einfachsten „rein konformationellen" Aspekte analysiert, das heißt jene Informationen die in den Matrizen V enthalten sind.

2.2. MOLEKÜLE, DIE NUR AXIALE CHIRALITÄT AUFWEISEN

Die Natur und die relative Anordnung der Liganden in Bezug auf eine Torsionsachse führt häufig zu einer chiralen Struktur.

Für zwei äußerst einfache Beispiele wie dies II und V aus Abb. 1 sind, kann man folgende rein konformationelle Matrizen V'_{II} und V'_{V} schreiben:

$$V'_{\mathrm{II}} = \begin{bmatrix} M_\alpha & 0 \\ M_\beta & + \end{bmatrix}; \quad V'_{\mathrm{V}} = \begin{bmatrix} M_\alpha & 0 \\ M_\beta & - \end{bmatrix} \tag{10}$$

Von matriziellem Standpunkt aus besteht folgende Beziehung zwischen V'_{II} und V'_{V}:

$$\begin{bmatrix} M_\alpha & 0 \\ M_\beta & + \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 \\ 0 & - \end{bmatrix} = \begin{bmatrix} M_\alpha & 0 \\ M_\beta & - \end{bmatrix} \tag{11}$$

oder, in andrer Benennung:

$$V'_{\mathrm{II}} \cdot F_a = V'_V \tag{11'}$$

Die Matrix

$$F_a = \begin{bmatrix} 1 & 0 \\ 0 & - \end{bmatrix}$$

die den Übergang von V'_{II} zu V'_V verwirklicht, weist folgende Eigenschaft auf:

$$F_a^2 \cdot V' = V' \tag{11''}$$

wo: $F_a^2 = F_a \cdot F_a$; V' ist jedwelche konformative Matrix. Mit anderen Worten entspricht F_a der Widerspiegelung bei beschränktem konformationellen Niveau, während F_a^2 zwei aufeinanderfolgenden Widerspiegelungen, ebenfalls in beschränktem konformationellem Sinn, entspricht.

Man bemerkt, daß zwischen den Konformeren II und V eine Beziehung der Enantiomerie besteht, deren matrizielle Ausdrucksweise durch die Gleichung (11) erreicht wird.

Folgender allgemeiner Satz kann ausgesagt werden: Ein Konformer ist chiral dann und nur dann, wenn die Beziehung

$$V \cdot F \neq V \tag{12}$$

besteht.

Man kann nämlich feststellen, daß für die Beispiele aus Abb. 1 die Matrizen V'_{I} und V'_{IV} wie folgt geschrieben werden können:

$$V'_{\mathrm{I}} \cdot F = V'_{\mathrm{I}}; \quad V'_{\mathrm{IV}} \cdot F = V'_{\mathrm{IV}} \tag{13}$$

Vergleicht man nun die Beziehungen (13) mit (12), so folgt daraus, daß sie achiral sind.

Die Beispiele II, III, V, VI sind der Beziehung (12) gemäß chiral.

2.3. AXIALE CHIRALITÄT IN GEGENWART ANDERER CHIRALITÄTSELEMENTE

Für einen möglichst allgemeinen Fall ist es notwendig auch die konfigurativen Aspekte zu behandeln, sowohl jene der Liganden, als auch jene der die Achse bestimmenden Atome, d.h. die Matrizen W und V zu verwenden. Im Sinne der Beziehung (9) bedeutet dies, die Matrix $\mathcal{W}$ zu verwenden.

Es sei nun $\overline{\mathcal{W}}$ die Matrix, die das Enantiomer des durch $\mathcal{W}$ charakterisierten Moleküls darstellt.

In dem nun Folgenden wird die Beziehung $\mathcal{R}$ bestimmt, die zwischen den zwei Matrizen besteht. Das heißt:

$$\mathcal{W}\mathcal{R}\overline{\mathcal{W}}$$

Wir bezwecken die Beziehung $\mathcal{R}$ so zu bestimmen, daß

$$\mathcal{W}\mathcal{R}\overline{\mathcal{W}} \Leftrightarrow \overline{\mathcal{W}}\mathcal{R}\mathcal{W} \tag{14'}$$

das heißt, man wird eine symmetrische Beziehung $\mathcal{R}$ suchen. Selbstverständlich wird $\mathcal{R}$ nicht reflexiv sein

$$\nexists\, \mathcal{W}\mathcal{R}\overline{\mathcal{W}}\,;\ \nexists\, \overline{\mathcal{W}}\mathcal{R}\mathcal{W} \tag{14''}$$

Zur Behauptung (14'') gelangen wir durch Analogie mit der Beziehung (12). Aus dem nun Folgenden wird man feststellen, daß (14'') wahr ist.

Die allgemeine Beziehung (14'') wird als (14) wie folgt neu geschrieben:

$$\mathcal{F}\mathcal{W} = \overline{\mathcal{W}} \Leftrightarrow \mathcal{F}\overline{\mathcal{W}} = \mathcal{W} \tag{14}$$

Zur Ableitung der analytischen Form des Operatoren $\mathcal{F}$, der eine Widerspiegelung des Moleküls in seiner Gesamtheit verwirklichen muß, ist folgende Bemerkung wichtig, die aus der Beziehung (14) hervorgeht:

Der Operator $\mathcal{F}$ hat einen umgekehrten Operator $\mathcal{F}^{-1}$ und zwar:

$$\mathcal{F}^{-1} = \mathcal{F}$$

Also besteht die Beziehung: $\mathcal{F}^{-1}\cdot\mathcal{F} = \mathcal{F}\cdot\mathcal{F} = \mathcal{F}^2 = E = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$. Das heißt, man sucht einen Operator, der eine Matrix 2×2 ist. Hier wurden die Ergebnisse von Kapitel 2.2 wieder aufgegriffen. Also ist die

Widerspiegelung eines Moleküls, die durch die Matrix $\mathcal{W}$ beschrieben wird, bei rein konformationellem Niveau, durch folgende Beziehung definiert :

$$\begin{bmatrix} 1 & 0 \\ 0 & F_a \end{bmatrix} \mathcal{W} = \begin{bmatrix} 1 & 0 \\ 0 & F_a \end{bmatrix} \cdot \begin{bmatrix} W \\ V \end{bmatrix} = \begin{bmatrix} W \\ F_a\, V \end{bmatrix} \tag{15}$$

Vergleicht man nun (15) mit (11′), so stellt man fest, daß in $\mathcal{W}$, durch die Anwendung des Operatoren $\begin{bmatrix} 1 & 0 \\ 0 & F_a \end{bmatrix}$ nur eine rein konformationelle Widerspiegelung verwirklicht wurde.

Es ist nützlich, in Anbetracht des nun Folgenden, auf zwei Eigenschaften des Operatoren F_a hinzuweisen :

$$\begin{aligned} F_a^{2k} &= F_a^2 \qquad (k = 1,\ 2,\ \ldots) \\ F_a^{2k+1} &= F_a \qquad (k = 1,\ 2,\ \ldots) \end{aligned} \tag{16}$$

Die Widerspiegelung der Konfiguration der die Achse bestimmenden Atome wird durch die Anwendung des Operatoren $\begin{bmatrix} F_{XY} & 0 \\ 0 & F_a^2 \end{bmatrix}$ gemäß folgender Beziehung erzielt :

$$\begin{bmatrix} F_{XY} & 0 \\ 0 & F_a^2 \end{bmatrix} \cdot \begin{bmatrix} W \\ V \end{bmatrix} = \begin{bmatrix} F_{XY} W \\ V \end{bmatrix} \tag{17}$$

In (17) wurde auch die Beziehung (11″) beachtet. Mit F_{XY} wurde der Operator bezeichnet, der durch folgende Beziehung definiert wird :

$$F_{XY} = \begin{bmatrix} \delta & 0 \\ 0 & \delta \end{bmatrix} \tag{18}$$

in welcher δ auf das Ausführen der Transponierung der Matrix hinweist :

$$\delta [a_{ij}] = [a_{ij}] \delta = [a_{ij}]^T \tag{19}$$

Also :

$$F_{XY} \cdot W = \begin{bmatrix} \delta & 0 \\ 0 & \delta \end{bmatrix} \cdot \begin{bmatrix} M_X \\ M_Y \end{bmatrix} = \begin{bmatrix} \delta M_X \\ \delta M_Y \end{bmatrix} = \begin{bmatrix} M_X^T \\ M_Y^T \end{bmatrix} \tag{20}$$

Zieht man die Ergebnisse der vorhergehenden Arbeit in Betracht, so stellt man wirklich fest, daß die Anwendung des Operatoren F_{XY} einer Widerspiegelung der Konfiguration der die Achse bestimmenden Atome gleichkommt. (ii)

Folgende Beziehung ist offensichtlich :

$$F_{XY}\cdot F_{XY} = F_{XY}^2 \sim E = \begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix} \qquad (20')$$

Also $F_{XY}^2\cdot W = W$, unabhängig davon, welches die durch (8) definierte Matrix ist.

Die Widerspiegelung der Konfiguration der Liganden (iii) wird durch folgende Beziehung definiert :

$$\begin{bmatrix}F_n & 0\\ 0 & F_a^2\end{bmatrix}\cdot\begin{bmatrix}W\\ V\end{bmatrix} = \begin{bmatrix}F_n W\\ V\end{bmatrix} \qquad (21)$$

Bei der Ableitung der Beziehung (21) wurde auch die Beziehung (11') beachtet. F_n ist der Operator, der durch folgende Matrix definiert wird :

$$F_n = \begin{bmatrix}F & 0\\ 0 & F\end{bmatrix},\ \text{wo}: F = \begin{bmatrix}\delta & 0\\ 0 & \delta\end{bmatrix}$$

Also : $F \equiv F_{XY}$

Führt man das Produkt $F_n.W$ aus, so erhält man :

$$F_n\cdot W = \begin{bmatrix}F & 0\\ 0 & F\end{bmatrix}\cdot\begin{bmatrix}M_X\\ M_Y\end{bmatrix} = \begin{bmatrix}FM_X\\ FM_Y\end{bmatrix}$$

Da M_X und M_Y Matrizen 2×2 sind, während $[m]$ Glieder aus M_X order/und M_Y darstellen, bemerkt man, daß die Glieder in FM_X und FM_Y $[m]^T$ sein werden. Indem wir von neuem von den Ergebnissen der vorhergehenden Arbeit[2] Gebrauch machen, stellt man fest, daß sich in den Matrizen FM_X und FM_Y Liganden befinden, die auch in den Matrizen M_X und M_Y vorkommen, aber mit widerspiegelten Konfigurationen.

Für den Operator F_n sind folgende Beziehungen wahr :

$$F_n\cdot F_n = F_n^2 \sim E = \begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix} \qquad (22)$$

$F_n^2\cdot W = W$ für jedwelche durch die Beziehung (8) definierte Matrix W.

Um die analytische Form des Operatoren F_n zu bestimmen, ist die Anwendung folgender Bemerkungen notwendig :
Man führt mit einem System, in unserem Fall mit einem organischen Molekül, eine Reihe von Widerspiegelungsoperationen aus. Man stellt fest, daß das Ergebnis der Anwendung des gesamten Widerspiegelungsoperatoren $\mathcal{F}$ der Anwendung des Produkts der mit F_a, F_{XY} und F_n gebildeten Operator-Matrizen gleichwertig ist :

$$\mathcal{F} = \begin{bmatrix}1 & 0\\ 0 & F_a\end{bmatrix}\cdot\begin{bmatrix}F_{XY} & 1\\ 0 & F_a^2\end{bmatrix}\cdot\begin{bmatrix}F_n & 0\\ 0 & F_a^2\end{bmatrix} \qquad (23)$$

Aus der physikalischen Natur des gestellten Problems kann man feststellen, daß $\mathcal{F}$, der durch die Beziehung (23) definiert wird, invariant in Bezug auf die Permutationen der Faktoren von der rechten Seite ist. Also ist :

$$\mathcal{F} = \begin{bmatrix} F_{XY} \cdot F_n & 0 \\ 0 & F_a \end{bmatrix} \tag{24}$$

die Form des gesuchten Operatoren. Die Beziehung (24) wurde unter Beachtung der Beziehung (16) festgelegt, wonach :

$$F_a^5 = F_a$$

Man kann nun die Tatsache überprüfen, daß der durch die Beziehung (24) definierte Operator $\mathcal{F}$ die Beziehung $\mathcal{R}$, die durch (14′) definiert wird, darstellt, und zwar folgendermaßen :

$$\mathcal{F} \cdot \mathcal{W} = \begin{bmatrix} F_n \cdot F_{XY} \cdot W \\ F_a \cdot V \end{bmatrix} = \overline{\mathcal{W}} \tag{25}$$

Beachtet man die Definition der Enantiomerie, so stellt man fest, daß die Beziehung (25) wahr ist. Durch die Beziehung (25) wurde ein Sinn aus der Beziehung (14) klargelegt. Ein zweiter Sinn wird gezeigt, indem man beweist, daß die Beziehung (25) symmetrisch ist, wie dies aus (26) folgt :

$$\mathcal{F}\mathcal{W} = \overline{\mathcal{W}} \,|\, \mathcal{F}$$

$$\mathcal{F} \cdot \mathcal{F}\mathcal{W} = \mathcal{F}\overline{\mathcal{W}} \tag{26}$$

Verwendet man die Beziehungen (16), (20′), (22), so findet man :

$$\mathcal{F} \cdot \mathcal{F} = \mathcal{F}^2 = \begin{bmatrix} F_n \cdot F_{XY}^2 & 1 \\ 0 & F_a^2 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

Aber : $\mathcal{F}^2 \mathcal{W} = E \cdot \mathcal{W} = \mathcal{W}$ (27)

Mit Hilfe von (27) wird die Beziehung (26) :

$$\mathcal{W} = \mathcal{F}\overline{\mathcal{W}}$$

Also wurde gezeigt, daß :

$$\mathcal{F}\mathcal{W} = \overline{\mathcal{W}} \Leftrightarrow \mathcal{W} = \mathcal{F}\overline{\mathcal{W}}$$

das heißt die Beziehung (14) erfüllt ist.

$\mathcal{F}$ erfüllt offensichtlich die Beziehungen (14″) Unter Beachtung des vorhergehend Behandelten kann man den folgenden Satz behaupten :

Gegeben sei ein organisches Molekül, das durch die Matrix $\mathcal{W}$ beschrieben wird. Dieses Molekül ist achiral auf allen Niveaus (i, ii, iii) dann und nur dann, wenn :

$$\mathcal{F}\mathcal{W} = \mathcal{W} \tag{28}$$

Um Beziehungen der Diastereoisomerie zu erhalten, genügt es den Operatoren $\mathcal{F}$ mit einigen der hier definierten Operatoren zu bilden (F_a, F_n, F_{XY}), die entsprechend der gegebenen Situation gewählt werden.

SCHLUSSFOLGERUNG

Die Verwendung der matriziellen Schreibweise für die Charakterisierung der axialen konformationellen Chiralität erlaubt eine mathematische Ausdrucksweise der chiralen Beziehungen zwischen den Konformeren. Gleichfalls wurde die analytische Form des Operatoren der Widerspiegelung für verschiedene Charakterisierungsniveaus der Struktur der Konformeren abgeleitet, das heißt bei rein konformationellem Niveau, beziehungsweise beim Niveau, in dem auch die Konfiguration der die Achse bestimmenden Atome oder auch die Konfigurationen der von der Achse abzweigenden Liganden eingeschlossen wurden.

HETEROCYCLIC ORGANOBORON COMPOUNDS. XV*

BORONIUM CHELATE SALTS AND BERYLLIUM CHELATES OF 1,3-KETOENOLS WITH DISTURBED RESONANCE IN THE CHELATE RING

ELENA IŞFAN and A. BARABÁS

Institute of Atomic Physics, P. O. Box 35, Bucharest

Received November 9, 1972

Chelate complexes of the $(L_2B)^+X^-$ and L_2Be types, in which L = ethyl acetoacetate, 2-acetylcyclohexanone, 2′-hydroxy-acetophenone (2-acetyl-phenol) or 2′-hydroxy-5′-methyl-acetophenone (2-acetyl-4-methylphenol), $X^- = SbCl_6$, ClO_4 or $FeCl_4$, were prepared and characterized by UV, IR ^1H- and ^{11}B-nmr spectra. The influence of factors disturbing the electron delocalization in the chelate ring on the properties of these chelates is discussed.

INTRODUCTION

In previous papers in this series [1-3] and related works [4-6] various investigations were reported on $(L_2B)^+X^-$ and L_2Be complexes, having 1,3-diketones of different structures as chelating ligands, LH. From these studies several conclusions could be drawn concerning the dependence between structure and properties of these chelate complexes. A brief summary of these will be given below.

1. In all chelates there are six electrons delocalized on the 1,5-oxa-oxonia-pentadienic system of the ligand, in the sense of the formulae I – III. Thus $R' = R'' = CH_3$ groups appear in ^1H-nmr

---

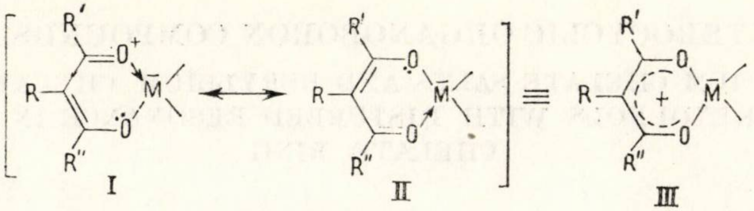
spectra as magnetically equivalent.



2. Aromatic R', R'' substituents decrease the excitation energy (π→π * transition) of the delocalized electronic system of the chelate ring by conjugation. As ^{1}H-nmr evidence indicates, these groups are coplanar with the chelate ring. Inductive effects of the R', R'' groups (e.g. R' = CF_3) seem to have no significant influence on the above mentioned electronic trasition.

3. π-Electrons of the R = C_6H_5, $COCH_3$, COC_6H_5 substituents are not conjugated with the delocalized system of the chelate ring, having a minor influence on its excitation energy. ^{1}H-nmr data suggest that the two π systems are non-coplanar. Inductive effects of R groups seem to lower the π→π * transition energy in the chelate ring.

In this work compounds are studied, whose R, R', R'' substituents perturb the chelate ring resonance. Complexes of structurally analogous ligands, but without perturbed resonance, are used as reference : acetylacetone for ethyl acetoacetate and 2-acetyl-cyclohexanone for 2-acetylphenol.

For convenience, the following abbrevations will be used for chelating ligands referred to in this work :

ethyl acetoacetate — acacoetH
2-acetyl-cyclohexanone — acyhexH
2'-hydroxy-acetophenone (2-acetyl-phenol) — acphoH
2'-hydroxy-5'methyl-acetophenone (2-acetyl-4-methylphenol) — — meacphoH
2,4-pentanedione (acetylacetone) — acacH
3-methyl-2,4-pentanedione (methylacetylacetone) — meacacH.

EXPERIMENTAL

1. Syntheses of ligands : Commercial acetoacetic ester was distilled before use. 2-Acetylcyclohexanone was prepared by BF_3-catalyzed acetylation of cyclohexanone.[7] 2-Acetyl-phenol and 2-acetyl-4-methylphenol were obtained by Fries transposition [8] of the appropriated esters.[9]

2. *Syntheses of the boronium chelate salts.* 20 mmoles of chelating ligand (LH) were dissolved in 5 ml of dry dichloromethane and 2.8 ml (2.2 g, 10 mmoles) of tri-(n-butyl)-borate were added.

---

[9] A. Spassow, *Chem. Ber.*, **75**, 779 (1942).

This mixture was cooled to − 40° and dry HCl gas was bubbled through for ca. 30 min. A solution of the corresponding chelated complex boronium chloride, $(L_2B)^+Cl^-$ resulted this way. Isolable salts were prepared by adding an appropriate anion-forming component in dichloromethane solution : 1.3 ml (3.0 g, 10 mmoles) of $SbCl_5$, 1.6 g (10 mmoles) of $FeCl_3$ or 10 mmoles of anhydrous $HClO_4$ in dichloromethane. These salts were isolated by concentration and recrystallized as shown in Table 1.

3. *Syntheses of the beryllium chelates.* The free ligand, LH, (20 mmoles) was dissolved in 5 ml of ethyl acetate. This solution was heated to reflux and a solution of 0.8 g (10 mmoles) of dry $BeCl_2$ in 25 ml of ethyl acetate was dropped into. The refluxing was continued for several hours, till the evolution of HCl ceased. The solvent was then evaporated *in vacuo*, and the complex purified by recrystallization, as indicated in Table 1.

bis-(Ethyl acetoacetato)-beryllium was prepared also in aqueous medium : 1.8 g (10 mmoles) of $BeSO_4.4H_2O$ were added to 5 ml of saturated sodium acetate solution and this mixture was shaken with 2.6 ml (*ca.* 2.6 g, 20 mmoles) of ethyl acetoacetate. The emulsion resulted was extracted with benzene and the organic layer fractionated to give a 10% yield of product. Non-reacted beryllium ion can be recovered from the aqueous phase with acetylacetone.

bis-(Ethyl acetoacetato)-beryllium was reported in literature, [10] *bis*-(2-acetyl-phenolato)-beryllium was prepared earlier in our laboratory. [11] *bis*-(2-Acetyl-cyclohexanonato)-beryllium was studied potentiometrically [12] but not isolated as pure substance.

4. *Analyses and spectra.* Elementary analyses for carbon and hydrogen were effected by standard combustion. Chlorine was determined by argentometric titration. Electronic spectra were recorded in 1,2-dichloroethane solution by a CF−4 Optica-Milano double-beam recording spectrophotometer. Infrared spectra were taken on a Carl Zeiss-Jena UR−10 instrument. Nuclear magnetic resonance spectra were recorded by Perkin Elmer R 10 and R 12 instruments. ^{11}B-nmr spectra were taken at a frequency of 19.2519 MHz with external $BF_3.Et_2O$ as reference.

RESULTS AND DISCUSSION

Electronic spectra of the studied complexes, the free ligands and of some analogous complexes used as reference compounds are shown in tables 2−4. Based on previous studies,[1−3] the absorption maxima in the column labelled with Z were attributed to the $\pi\to\pi^*$ transition in the chelate ring. The wavelength of this absorption is inversely proportional to the excitation energy of the delocalized electrons in the chelate ring, which in turn is inversely proportional to the resonance energy of this delocalized system. The wavelength in question will measure thus the extent of delocalization of the π electrons of the chelate ring.

As may be seen from table 2, an $R' = OC_2H_5$ substituent produces a hypsochromic shift of the $\pi\to\pi^*$ transition compared to the reference compound with $R' = CH_3$. The value $d\lambda$ of this shift is measured as the wavelength difference for the $\pi\to\pi^*$ transition (Z) in the studied compound

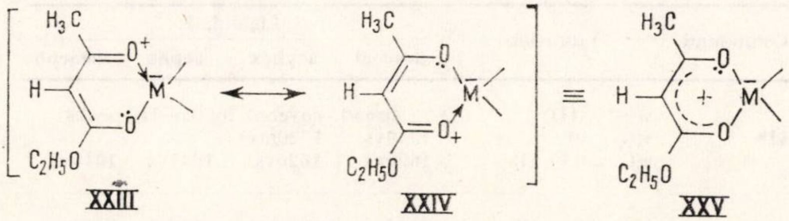
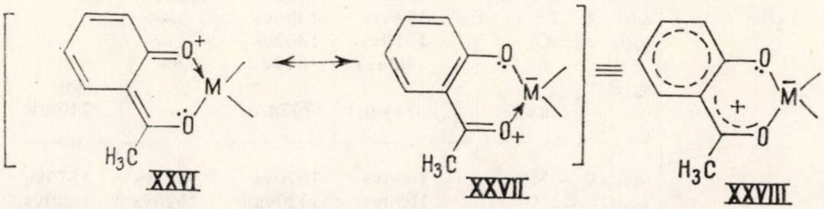
a, compared to the corresponding methyl-acetylacetone compound.

(ethyl acetoacetate derivatives in Table 2) and the analogous compound chosen as reference (acetylacetone derivatives in Table 2). The negative dλ values obtained mean less resonance energy, restricted delocalization in the chelate ring produced by the $R' = OC_2H_5$ substituent. $R', R'' = C_6H_5$ substituents, conjugated with the chelate ring, produced[1] large positive dλ shifts against the same reference compounds (VII – IX), having $R', R'' = CH_3$.

Similarly, the benzo- R—R′ substituent in the 2-acetyl-phenolcompounds (Table 3), produces a hypsochromic shift of the $\pi \rightarrow \pi^*$ transition, compared to the saturated analogues, the 2-acetyl-cyclohexanone compounds (Table 4), having tetramethylene R—R′ substituent. As the respective dλ values are also negative, it can be assumed, that the benzo- R—R′ substituent reduces the extent of delocalization in the chelate ring compared to the reference. This hypsochromic effect on the $\pi \rightarrow \pi^*$ transition in the chelate ring due to the benzene ring condensed to it is of electronic (mesomeric) rather than of steric or any other nature. The saturated acetyl-cyclohexanone compounds chosen as reference behave "normally", giving no significant shifts compared to the analogous compounds of methyl-acetylacetone, (Table 4), having $R, R', R'' = CH_3$ substituents to which no mesomeric and only very small inductive or steric effects could be attributed.

Consequently, it must be admitted that both structural elements (an $R'=OC_2H_5$ substituent and a condensed benzene ring) perturb the resonance in the chelate ring. This perturbation in chelates of ethyl acetoacetate and of 2-acyl-phenols may be performed as shown in formulae XXIII–XXV and XXVI – XXVIII, respectively, where the limiting structures XXIV and XXVII, respectively, prevail in the resonance hybrid.





Unlike I and II, the canonical structures XXIII and XXIV, respectively XXVI and XXVII, are energetically non-equivalent, which means in terms of the valence bond theory less resonance energy. The MO method will express this as less extended delocalization of the chelate ring conjugated system in the sense of formulae XXV or XXVIII, compared to formula III. Structure XXIII will have a higher energy content than its counterpart XXIV, because the strong donor OC_2H_5 substituent will favour the apparition of the positive charge at the oxygen atom of the adiacent carbonyl group, as in XXIV. Structure XXVI will be of higher energy than XXVII due to its *o*-chinoidic nature.

Complexation to Be or B causes throughout a bathochromic shift of the $\pi\rightarrow\pi^*$ transition, that is complexation will favour delocalization in the chelate ring, compared to the free ligand, LH. This is shown in Tables 2–4 as the difference Λ between the wavelengths Z for the complex in question and the free ligand. As may be seen, Λ values are non-negative for all complexes.

Infrared spectra of the studied compounds deserve some comment. Most of the observed intense absorption peaks could be attributed to individual vibrations by an empirical procedure, using results of previous work[1-3] and of some studies on similar compounds[13,14]. Some of these peaks are shown in Table 5. The broad (2500–3300 cm^{-1}) absorption of

the hydrogen-bonded OH in the free ligands LH is missing in the complexes. The stretching frequency of the non-coordinated C=O groups, appearing in ethyl acetoacetate and in 2-acetyl-cyclohexanone is also non-existent in the spectra of their complexes. Carbonyl groups in 2-acetyl-phenols are completely hydrogen-bonded .[15] The frequencies of coordinated C=O groups in complexes ($C \cdots O \rightarrow M$) are lower than in the free ligands ($C \cdots O \rightarrow H$), reinforcing the conclusion drawn above, that complexation of either Be or B implies stronger coordinative bonds than those to hydrogen. For attribution of metal-ligand absorption frequencies, the analysis of Funck [14] was followed. Two vibrations of the BeO_4 tetrahedron appear as absorption bands. They were attributed as antisymmetric stretching vibrations degenerated into two components : one perpendicular (*n*) and the other parallel (*ax*) to the symmetry axis of the molecule. (Rigorously speaking, there is no symmetry axis in these complexes with $R' \neq R''$; they consist of a racemic mixture of two enantiomers. In this discussion the symmetry axis considering $R' = R''$ is meant). The same vibrations appear for the BO_4 tetrahedron, but with a further splitting due to the isotopes ^{10}B and ^{11}B.

[15] S. BĂDILESCU and I. BĂDILESCU, *Rev. Roumaine Chim.*, **10**, 103 (1965).

Some nuclear magnetic resonance frequencies of the studied compounds are shown in Table 6. The effect of the $R' = OC_2H_5$ substituent on the proton chemical shifts may be treated in similar terms as electronic spectra were discussed above. The chemical shift differences dδ between ethyl acetoacetate compounds ($R' = OC_2H_5$) and acetylacetone compounds ($R' = CH_3$) are shown for the $R'' = CH_3$ and $R = H$ protons. The throughout negative dδ values show that an $R' = OC_2H_5$ group produces an upfield shift (i.e. more screening) of the protons considered. This may be explained with less delocalization in the chelate ring compared to the reference compound. This explanation is supported by the observation that (absolute) dδ values are an order of magnitude greater for the $R = H$ proton attached directly to the chelate ring, than for the $R'' = CH_3$ protons. The chemical shift differences Δ between complexes and their free ligands are positive, suggesting that delocalization in the chelate ring is more advanced in the metal complexes. This applies for Be complexes only, because in boronium salts the overall positive charge in the complex cation produces large positive Δ shifts. In this connection it is most interesting to note that Δ values near to zero were observed for the boronium salts of the 2-acyl-phenols (see Table 6).

^{11}B-chemical shifts are similar to those observed for boronium complex salts of other 1,3-ketoenols, and they are shown here only as proof for the assigned structure. ^{11}B-resonance in boron 1,3-diketonates will be discussed elsewhere.[16]

From the discussion of the results outlined in this work a further point may be added to the conclusions concerning structure — properties relationships in 1,3-diketone chelates, quoted in the introduction :

ELECTRONIC SPECTRA AND ACIDITY CONSTANTS OF SOME 2-AMINO-5-SUBSTITUTED THIAZOLES

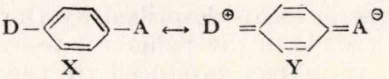
DAN SUCIU

Oncological Institute, Str. Republicii nr. 34–36, Cluj, Romania

Received July 17, 1972

The ultraviolet data and acid dissociation constants of some 2-amino-5-substituted thiazoles support the assumption that between the electron-donating group 2-amino and an electron-attracting 5-substituted group a charge polarization should be possible. Evidence is presented about the common feature of this effect with the intramolecular charge-transfer which occurs in *para*-substituted anilines.

The highly unsymmetrical aromatic compounds of the type (*X*) where (*D*) group is an electron-donating substituent (amino or alkyl substituted amino) and the (*A*) group is an electron-attracting substituent (nitroso, nitro, aldehyde, acetyl, carboxyl etc.) have two absorptions in ultraviolet. The stronger absorption found in the near ultraviolet region has been assigned to a transition which was qualitatively represented as being from the ground state (*X*) to the excited state (*Y*).[1,2] In the present work we report some ultraviolet data which support the assumption that in the 2-amino-thiazole series almost similar transitions with those of the type (*X*↔*Y*) may be possible.



X Y

The electronic spectra in ethanol of some 2-amino-4-methyl-5-acylthiazoles (Table 1) show strong absorptions in the region 325–345 nm and weaker absorptions between 220–262 nm, from this point of view the spectra being similar with those reported for *para*-substituted anilines[1,2].

Taking into account the unsymmetrical distribution of the charge density in the 2-aminothiazole molecule,[3] a restriction of the charge polarization between the 2-amino group and an electron-attracting substituent located in the 4 or 5 positions of the ring should be excepted. On the

basis of the limit mesomeric forms described by Dorn *et al.* [4] for 2-aminothiazole an attempt was made in the Scheme 1 to explain, with the aid of similar representations, the effect produced by the presence of the keto group on the charge distribution in the 2-amino-4-methyl-5-acetylthiazole molecule. The mesomeric forms (b−d) show the charge distribution of the amidine system, and the structures (e−h) the charge polarization along the long axis of the molecule. Both effects could be qualitatively emphasized on the basis of ultraviolet spectra.

The protonation of 2-aminothiazoles takes place at the endocyclic nitrogen atom. [4] Compounds **10**−**15** (Table 2) exhibit quite similar spectra in neutral and acid media. On the contrary, for the 2-amino-5-substituted thiazoles **1**−**6** (Table 1) and **8**, **9** (Table 2) the near ultraviolet absorption band is shifted to shorter wavelengths in acid solution. The ammonium salt of *p*-aminoacetophenone (**7**) also absorbs at a shorter wave length than the corresponding free base (Table 2). All these compounds (**1**−**15**) are protonated in 0.1 N−HCl solution, but the blue shift of the near ultraviolet absorption band could be observed only for *p*-amino-acetophenone and 2-amino-5-substituted thiazoles carrying a strong electron-attracting group (phenyl or acetyl) in the 5 position of the ring. This could

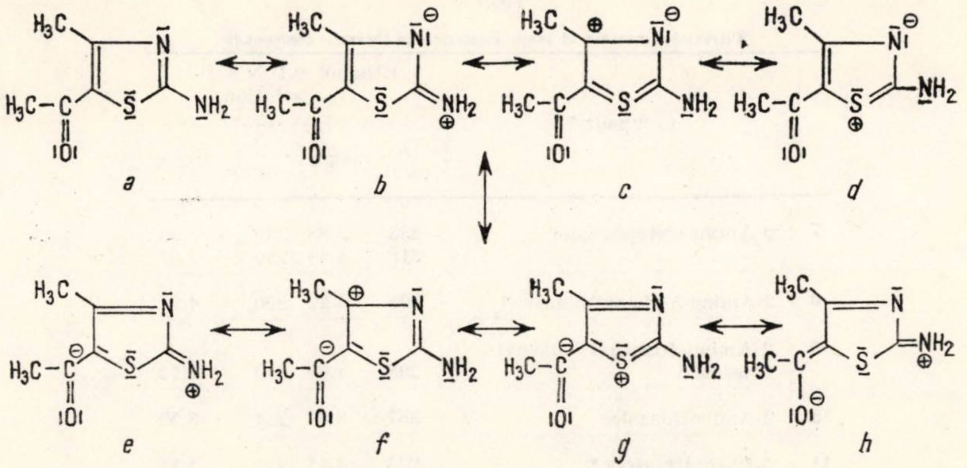

Scheme 1. Mesomeric forms of 2-amino-4-methyl-5-acetyl-thiazole.

be explained assuming that protonation prevents the intramolecular charge transfer of the type (*a* ⟷ *h*) or (*X* ⟷ *Y*).

2-Amino-4-phenylthiazole **(18)** and 2-allylamino-4-acetyl-thiazole **(19)** also exhibit two absorptions in ultraviolet. However, the bands which appear in the near ultraviolet region have lower intensities as compared with those produced in the blue region of the spectra, in contrast with *para*-substituted anilines [1,2] and 2-amino-5-substituted thiazoles (Table 1 and 2). This effect is probably due to the position of the electron attracting group (acetyl or phenyl) which does not favour the transmission of the mesomeric effect through the molecule, similarly as in the *meta*-substituted aromatic compounds.

The ultraviolet data lead to the conclusion that an intramolecular charge transfer nearly similar to that produced in molecules like *para*-substituted anilines may be possible in the 2-amino-thiazole series only for 2-amino-5-substituted thiazoles, when the 5-substituted group has strong electron attracting properties. The charge polarization is highly probably facilitated along the $-\overline{\underline{S}}-$ bridge as it is emphasized in the mesomeric structures (*e* — *h*) (Scheme 1).

Accordingly, for molecules of the 2-amino (5,4′)-2′-amino-bithiazole type **(19—21)** in the 2-amino-5-substituted thiazole group a similar charge polarization should be excepted, the electron attracting substituent being the 4′-thiazolyl group. The mesomeric structure (*W′*) indicates the stabilization tendency by resonance of this excited molecular state. The assumption made above is qualitatively supported by the ultraviolet spectra of these compounds, because the near ultraviolet absorption band found

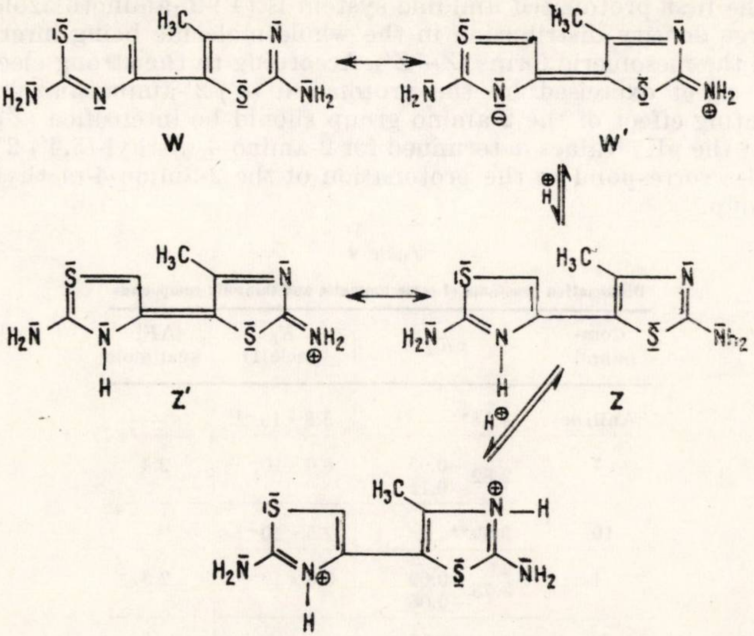
in the spectra recorded in ethanol is absent in the spectra recorded in 0.1 N—HCl solution (Table 3).



Quantitative data regarding the intramolecular charge transfer which occurs in molecules like *p*-aminoacetophenone or 2-amino-5-substituted thiazoles were obtained on the basis of the acid dissociation constants (Table 4). The pK_a values of *p*-aminoacetophenone as well as those of 2-amino-5-substituted thiazoles are lower than those determined for aniline and 2-aminothiazole respectively, according to the charge deficit induced in the ring by the electron-attracting groups (acetyl or 4′-thiazolyl). The conjugation energy $|\Delta F|$ (Table 4) required for the charge polarization between the donating and the accepting group was calculated following the relation :

$$\Delta F = -RT \ln \frac{K_1}{K_2}$$

K_1 = basicity constants of aniline and 2-aminothiazole, respectively,

K_2 = basicity constants of *p*-aminoacetophenone, 2-amino-5-acetylthiazoles and 2-amino-(5,4′)-2′-aminobithiazoles.

The $|\Delta F|$ values corresponding to *p*-aminoacetophenone and 2-amino-5-acetylthiazoles were estimated to be about 2.5 kcal/mole (Table 4).

For bithiazoles the $|\Delta F|$ values are significantly higher (about 3.5 kcal/mole), probably because in these compounds there are two amidine systems which are protonated at different hydrogen ion concentrations. Very likely, the first protonated amidine system is (4′)-2′-aminothiazole group, the charge density distribution in the whole molecule being intermediate between the mesomeric forms ($Z \leftrightarrow Z'$). According to the strong electron-attracting effect exercised by the protonated (4′)-2′-aminothiazole group, the donating effect of the 2-amino group should be intensified (Z). It follows that the pK_a values determined for 2-amino-4-methyl-(5,4′)-2′-aminobithiazoles correspond to the protonation of the 2-amino-4-methyl-5-thiazolyl group.

A STUDY OF INTERMEDIATES IN THE HANTZSCH REACTION. A NEW METHOD TO OBTAIN 5-ACETYLTHIAZOLE DERIVATIVES

I. SIMITI, MIOARA COMAN, I. SCHWARTZ

Institute of Medicine and Pharmacy, Laboratory of Organic Chemistry
Str. V. Babeş 41, Cluj, Romania

Received November 12, 1971

The present paper investigates the chemical and physico-chemical properties of intermediates resulted in Hantzsch reaction. A new method is proposed to obtain some 2-aryl-4-R-5-acetylthiazoles.

In previous publications we investigated the condensation of symmetrical dichloroacetone with aryl-thioamides, N-arylthiourea and thiosemicarbazones under different conditions. [1–3]

We noted that in acetone solutions at room temperature these reactions occur differently depending on the thioamidic component. Aryl-thioamides unlike N-aryl-thiourea and thiosemicarbazones do not give the appropriate thiazoles, but intermediate ones. These intermediates if neutralized with ammonia or bicarbonate or by simple washing with water, yield the corresponding bases. On heating them in alcoholic solution or in contact with concentrated sulphuric acid, thionylchloride or alkaline hydroxides at room temperature they yield the corresponding 2-aryl-4-chlormethylthiazoles. Contrary to the corresponding alkyl derivatives, the aryl compounds are stable.

Since an influence of the halocarbonylic component could be also invoked, we investigated various halocarbonylic components. The reaction mechanism was the same in all cases. Hooper and Johnson [4] considered these intermediates as iminothioether-hydrochlorides /*A*/. Later, however,

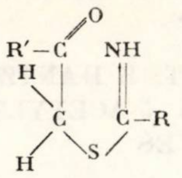
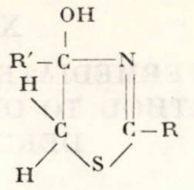
Metzger *et al.*[5] who was investigating the intermediate resulted from the reaction of thioacetamide with symmetrical dichloracetone, assigned a 4-hydroxy-Δ_2-thiazoline /B/ structure to it.



/A/.



/B/.

In order to elucidate the mechanism of the Hantzsch reaction we undertook a physico-chemical and kinetic study of these intermediates.

The IR and UV spectra of such intermediates, hydrochlorides, bases and the corresponding thiazoles are given in table 1. The I.R. spectra were recorded as KBr pellets with an IR 27 G Shimadzu-spectrometer, the UV spectra in methanol with a VSU–2 Zeiss-Jena Spectrophotometer.

The IR data show that both the hydrochlorides and bases give a band between 1590–1620 cm^{-1} which can be assigned to the endocyclic $C = N$ bond (the exocyclic $C = N$ appears generally above 1630 cm^{-1}; for the substance XVI it appears at 1660 cm^{-1}).[6] The intermediate hydrochlorides and bases give always a band between 3080 and 3100 cm^{-1} which usually can be attributed to the hydroxyl. Such bands appear also in the case of thiazoles unsubstituted in position 5, but are missing in the substituted thiazoles.[7] Since this band appears also in thiazolines which are unsubstituted in position 5, and without a hydroxyl group in 4, it cannot be assigned with certainty to the hydroxyl group.[8] However, since Metzger confirmed the presence of the hydroxyl group in 2-methyl-4-hydroxy-4-chloromethyl-Δ_2-thiazoline by NMR measurements the mentioned band could be due to the hydroxy group.

The UV spectra of these intermediates, show a single absorption band at 242–255 nm contrary to the 2-phenyl-, 2-aniline- and 2-hydrazonothiazole derivatives which give two bands (Table 1).

Since under the influence of concentrated sulphuric acid or of sodium hydroxide the intermediates obtained in the condensation of phenyl-thioamide with symmetrical dichloracetone yield thiazoles, we investigated the influence of the pH for the range 0.5–10 on this process.

In the acid range (pH = 3.2) the absorption band of the substance, as seen in Fig. 1., is identical with that obtained in methanol, suggesting that it corresponds to the unprotonated form. The changes observed in

the UV spectra at subsequent lower pH values (2.5 ; 2.0 ; 1.8) indicate a partially protonation which is complete at pH = 1.5. (The spectrum is identical with that observed at pH = 0.5).

Increasing the pH values in the opposite direction from 0.5 to 3.2, the same absorption curves were obtained which demonstrates the reversible character of this process (Fig. 1). This excludes a possible conversion of the intermediate into 2-phenyl-4-chlormethyl-thiazole. On the other hand, the spectrophotometrically[9] determined basicity constant of III ($pK_{BH^+} = 1.48$) is different from that of 2-phenyl-4-chlormetyl thiazole which is 0.96.[10]

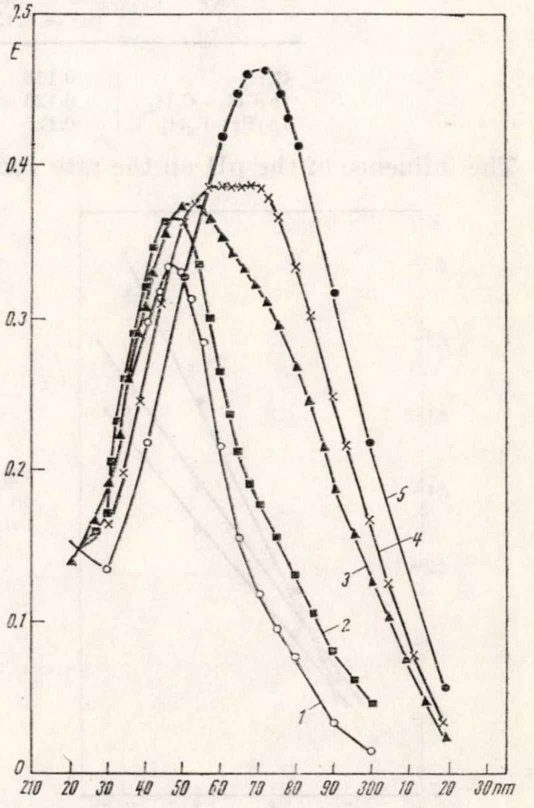

Fig. 1. — UV spectra of thiazolines in the pH range 1.5–3.2.

1, pH =3.2; *2*, pH=2.5; *3*, pH=2.0 *4*, pH=1.8; *5*, pH = 1.5.

The changes of the UV spectra within the basic pH range are even more evident. Thus, the bands in the 238–246 nm region belonging to the thiazoline disappear and others appear at 292–296 nm which are characteristic of the Ar-thiazole system (See table 1).

[10] I. Schwartz, Dissertation, Babeş-Bolyai University Cluj, 1970.

These experiments were carried out for the following pH values: 7.15; 7.65; 8.95. The processes occur according to the first order reactions. The rate constants determined at 25±0.2° are given in table 2.

Table 2

Rate constants for different pH-s

Ar	Rate constant 1/mol·min		
	pH = 7.15	pH=7.65	pH=8.95
C_6H_5	0.156	0.247	0.411
$(p)CH_3-C_6H_4$	0.126	0.218	0.300
$(p)Br-C_6H_4$	0.125	0.274	0.518

The influence of the pH on the rate constant is given in Fig. 2.

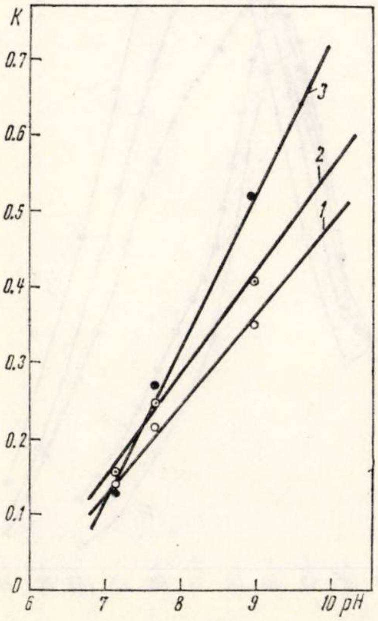

Fig. 2.—Dependence of the rate constant on the pH in the transformation of thiazolines into the corresponding thiazoles; *1*, x = $-CH_3$; *2*, x = $-H$; *3*, x = $-Br$.

A linear dependence can be observed. The influence of the substituents on the first order rate constant, as seen in table 2, at pH = 7.65 and 8.95, shows that the *p*-bromine accelerates the reaction, while the p-CH_3 group has an opposite effect in comparison with the unsubstituted derivative.

From our studies we can conclude that the presence of an $-NH-$ group in position 2 favours the formation of the thiazole but we were not able to isolate an intermediate. With phenyl and alkyl substituents in the same position and under certain conditions the intermediates could be isolated.

The appearance of these intermediates supposes apparently a simultaneous attack of both sulphur and nitrogen. Considering the difference in their nucleophylicity, we consider that sulphur is to attack first, followed immediately by the attack of the nitrogen. Our attempts to demonstrate the initial attack in a condensation reaction between a halocarbonylic and thioamidic component were unsuccessful.

By reacting the 2,4-dinitrophenyl-hydrazone of the symm. dichloracetone with thiobenzamide, a very stable cyclization product was obtained. The latter remained unchanged even after extended boiling in alcohol (10 h) or alcoholic solution of concentrated HCl (10–12 h).

According to the spectral data and kinetic studies we suppose that the isolable intermediates from a reaction between aryl-thioamide and different alfa-halocarbonyls are 4-hydroxy-Δ_2-thiazolines.

The chemical behaviour of these compounds supports such a presumption since they do not react with typical reagents of the $C = O$ group (2,4 DFH) which should be the case if iminothioethers were present. Furthermore, the $C = O$ absorbtion band is absent in the IR spectra.

Investigating comparatively the desulphuration reaction of thiazole, thiazoline and S-methyl-thioamide, evident differences can be observed.

At room temperature 2-phenyl-4-hydroxyl-4-chloromethyl-Δ_2-thiazoline with NaOH easily gives 2-phenyl-4-hydroxyl-methyl thiazole while 2-phenyl-4-chloromethyl thiazole yields the corresponding alcohol only under special conditions.

Since these intermediates easily undergo a cyclization at room temperature under the influence of conc. suplhuric acid we investigated their behaviour towards other dehydrating agents like acetic anhydride. Both 2-aryl-4-chloromethyl-4-hydroxy-Δ_2-thiazolines and 2-phenyl-4-hydroxy-Δ_2-thiazoline, after a short boiling with acetic anhydride give solid products with high melting points showing the characteristic reactions for the carbonyl group (2,4 dinitrophenylhydrazones ; oxymes and the corresponding 2-aryl-thiazoles). On reduction with Zn in HCl they yield 2-phenyl-4-methyl-5-acetyl thiazoles which we obtained also by other route. The compound XVII is identical with the product obtained by Kochetkov [11] in a condensation reaction and by Eiichi Haruki [12] in an oxidation process.

In conclusion, under the influence of acetic anhydride a dehydration reaction and the acetylation of position 5 occur simultaneously. This represents a new method to obtain 5-acetyl thiazoles *via* the corresponding thiazolines.

It is interesting to mention that this reaction occurs much easier with the corresponding thiazoline hydrochlorides. Investigating the action of acetic anhydride on 2-phenyl-4-chloromethyl thiazole hydrochloride and on 2-phenyl-4-chloromethyl thiazole regardless of the boiling time no modifications could be observed. This confirms the presumption that only hydroxythiazolines undergo simultaneous dehydration and acetylation reactions.

All ketones were submitted to the haloform reaction and transformed into the corresponding acids. The acid obtained by the haloform reaction of 2-phenyl-5-acetyl thiazoles is identical with that mentioned in the literature.[11,12]

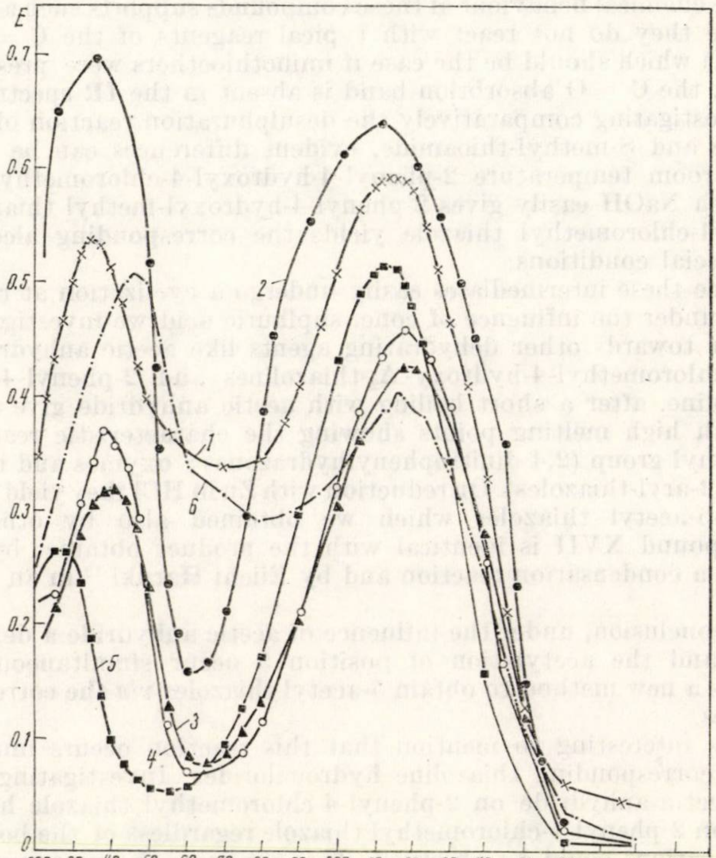

Fig. 3. — UV spectra of 5-acetyl thiazole derivatives.

1, 2-phenyl-4-methyl-5-acetylthiazole ; *2*, 2 -phenyl-4-chloromethyl-5-acetyl thiazole ; *3*, 2-p-tolyl-4-chloromethyl-5-acetyl-thiazole ; *4*, 2-*m*-tolyl-4-chloromethyl-5-acetyl thiazole ; *5*, 2-phenyl-5-acetyl thiazole ; *6*, 2-*p*-brom-phenyl-4-chloromethyl-5-acetyl-thiazole.

The structure of the 2-acetyl derivatives is supported also by their IR and UV spectra (Fig. 3). The mass-spectrum of 2-phenyl-4-chloromethyl-5-acetyl thiazole is also conclusive.

Received Octomber 6, 1972

In this work the specific volume-pressure-temperature relationship was studied in high-pressure additive-containing polyethylene of the ROPOL type, obtained by the I. C. I. process. From experimental data obtained under isothermal and isobaric conditions, were calculated the specific volume, the coefficients of isothermal compressibility (β_T), the ratio $\Delta V/V_{23^\circ}$ and the coefficients of thermal expansion (α), as well as the variation of the degree of crystallinity with the temperature, pressure and time.

The obtained data are in good accordance with prior results obtained with polyethylene types.

INTRODUCTION

The studies presented in this work belong to the field of supermolecular morphology and high polymer properties, a field we began to deal with in 1958, by the research made on low-pressure polyethylene (PE) obtained by amyl-sodium catalysis.[2–4]

---

* Presented at the second Meeting for General and Applied Physical Chemistry, Bucharest, 1–4 Sept. 1970.

In the period following 1960, and especially after 1964–1965, the specialists of many developed countries, Japan, USA, USSR and Germany arrived at the conclusion that the two most important problems of economy – the quality of the finished product and the production rate – can no more be solved in the case of polymers by the old method of repeated experiments, but only on the basis of the relations between the manufacturing processes and the inside morphology of the polymer.

The interest for the new direction of research has so much increased that, in a short time, it has become one of the modern spheres of research in polymers on world-wide scale, proving that supermolecular morphology is the fundamental problem for the study of the synthesis and processing of polymers.

In this sphere, we first studied – in a prior work [1] – the relationship pressure-volume-temperature-total induced crystallinity in high-pressure, no-additive-containing P.E. (grades 121, 322 and 721), manufactured at the Petrochemical Industrial Group – Ploieşti. In that work, a part of the literature known until 1968 was cited. Then, in the present work, the literature up to 1971 is cited with regard to the behaviour of polyolefines crystallizable from the melt in general, and especially of PE, in the pressure-volume-temperature relationship. As regards the measuring of the specific volume under pressure and of compressibility of PE and of other polymers, the works [5–17] are cited, of which [11–16] relate to other polymers than PE.

About melting and crystallization of PE and of other polyolefines under variable pressures from 1 to 30,000 at and temperatures up to 270°, the works [18–35] are known too.

In the works,[36-40] the morphology of PE crystallized under high pressures is particularly discussed, and in [41] the problem of PE hardening under pressure is treated.

To determine the degree of total crystallinity from calorimetric and specific volume data, the works [42,43] are important. From the above cited literature and from that mentioned in our prior work,[1] it does not clearly result if the studies have been carried out on additive — or nonadditive — containing polymers.

Therefore, we first studied nonadditive-containing PE,[1] and in the present work we present the results obtained with the same polyethylene, but containing additives, thus pointing out the role played by additives in thebehaviour of high-presure PE, manufactured at the Petrochemical Industrial Group-Ploieşti, in the pressure-volume-temperature-crystallinity relationship.

EXPERIMENTAL

The research has been carried out on high-pressure additive-containing PE, grades 121 A and 322 A, characterized by data given in Table 1. The molecular structure of the two grades of PE is characterized by a chain with many short branches : formed of methyl groups ($-CH_3$) arranged at random along the chain, a group at about 35 to 40 carbon atoms in the chain direction.

To study the two PE grades, plates of about 35 mm thickness have been compression moulded, from which have been processed (by mechanical cutting parallel to the PE plate thickness) cyclinders of 13±0,02 mm diameter and 30 mm length under the conditions described in the experimental part of the prior work.[1]

**) Calculated from the density (d_4^{25})of cylindrical PE specimen processed from a plate by mechanical cutting.

It has to be mentioned that during the granulation, additive introducing and plate compression moulding operations, the morphological structure is continuously modified when passing from the synthesized polyethylenes to the cylinders that have been submitted to the study, during which study they will have to suffer new changes, especially in crystallinity, according to the working conditions.

The study of the pressure-volume-temperature relationship has been performed on an improved equipment, the description and working method of which have been published in our prior work. [1]

The equipment is characterized by maintaining constant the temperature during the whole working interval with an accuracy of ± 0,25°, and by a perfect tightness of the compression chamber to avoid polymer loesses.

We mention that in works accomplished by other authors, these two characteristics have not been sufficiently taken into consideration, and this led to results that are not comparable for the same polymer. To this, the fact must be added that many of the prior works have been effected on narrow temperature and pressure ranges, and not on a large range so as to gain a complete knowledge about the phenomenon.

The present study has been carried out on a value range comprised between 23° and 300° and between 1o and 1800 at. The choice of these ranges was based on the fact that they include the usual values used in the polyethylene processing machines to obtain finished products.

PROCEDURE

For measurements, the PE specimen, previously degreased with analytical benzene, was weighed to the nearest fourth decimal and measured with an accurecy of ± 0,01 mm then it was introduced very slowly, under a slight compression, into the compression chamber through its lower part, after the upper piston had first been introduced.

In this way, the possibility of including air in the compression chamber is eliminated, taking into account the fact that the specimen diameter is by about 0.3 to 0.4 mm larger than the diameter of the compression chamber. After mould closing and its fitting on the general purpose machine for mechanical tests, the necessary temperature and pressure are attained, according to the desired working conditions.

Heating and cooling of the specimens were performed, as a function of isobaric conditions $(\partial V/\partial T)_{P=\mathrm{const}}$ or of isothermal conditions $(\partial V/\partial P)_{T=\mathrm{const}}$, according to the diagrams in Figures 2 and 3 of the work.[1]

In both measurement types, the changes of specific volume have been achieved with a constant rate of 0,10% volume changes per minute. The other experimental conditions were described in the same work.[1]

After compression, the polyethylene specimens were cooled under pressure down to 25°, then again measured and weighed.

Table 2

The influence of the time of maintining PE at constant T and P upon the degree of crystallinity (X) and its evolution with time

Presure * P, at	Time of maintaining at $T=100°$, min	Temperature (T), °C	Degree of crystallinity (X) in % after hours:

800	40	100	62.10	61.94	61.97	62.1	63.2
800	60	100	62.57	62.50	62.40	62.5	62.8
800	120	100	61.68	61.72	61.80	61.9	62.8

* The presure of 800 at represents the level to which pressure was raised after reaching the temperature of 100°.

The degree of crystallinity was determined at atmospheric pressure by the densimetric method[44,45] using for the specific volume of the completely amorphous phase (V_a^{25}) the value of 1.1165 ml/g and for the specific volume of the 100% crystalline phase (V_{cr}^{25}) the value of 1.0262 ml/g.[46]

Before effecting the thermodynamic study our researches were directed to checking the time interval in which the thermal equilibrium is reached.

The time required for reaching the equilibrium and eliminating the thermal gradients is comprised according to literature[1,30] between 15 and 60 minutes. Prolonging this time, for the same temperature, pressure and cooling rate conditions, we established the influence exerted by the time of maintaining at the equilibrium upon the variation of the specific volume and of the degree of crystallinity. The results are given in Table 2.

They show that by maintaining PE at the temperature of 100° and pressure of 800 at (parameters characterizing the lower limit of the range within which the crystallinity induced by pressure manifests itself) a time of 20 minutes is sufficient to attain the thermal equilibrium. The prolongation of the time to 120 minutes has only a slight influence upon the specific volume and the degree of crystallinity. Above this period of time, there is observed a tendency of diminishing the degree of crystallinity.

From data presented in the same table (columns 6 to 8), it may furthermore be seen that, after withdrawal of the PE specimens from the mould and allowing them to stand at normal room temperature and pressure, no substantial change in the degree of crystallinity will be found any more with time, this meaning that the induced crystallization process does not continue with time after taking off the pressure in the case of high-pressure additive-containing PE, as this is the case with other polyethylenes, such as the low-pressure AS polyethylene.[2]

THE EXPERIMENTAL RESULTS AND THEIR INTERPRETATION

The study of compressibility and crystallinity in high-pressure PE presumes the previous-knowledge of a very important parameter, the total specific volume, as well as of the variation of this parameter both with the pressure and with temperature under the conditions shown in the experimental part. For this purpose, first the *variation of the specific volume without outside action* was studied, that is the free volume expansibility.

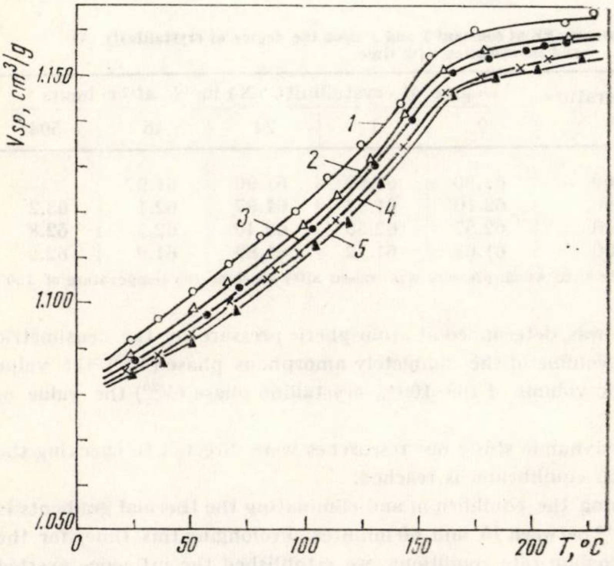

Fig. 1. — Variation of the **polyethylene** specific volume **without outside action.**

***1,* Polyethylene 721 N**: *2,* **Polyethylene 322 N**: *3,* Polyethylene 121 N: ***4,* Polyethylene 322 A**: *5,* Polyethylene 121:

A=Aditive-containing polyethylene; **N =NO-Aditive-co** taining polyethylen .

The specimens with and without additive, prepared and submitted to melting in the mentioned equipment, showed a variation of the specific volume which is presented in Figure 1.

It will be seen that independent of the fact that PE contains or not an additive, the general behaviour of the polymer will be the same. However, it will be noted that the specific volumes of the no-additive-containing polymers are a little greater than those of polymers containing additives, owing to the volatilization of the antioxidant and respectively of the sliding agent.

The common phenomenon in these processes is the transition of the polymer from the solid to the liquid state, which represents the melting of the polymer. From Figure 2, it may be seen that during melting the pressure increases with time up to 200 minutes, and from Figure 3, the increase of pressure with the temperature can be observed up to 160°, above which the pressure tends toward a constant value.

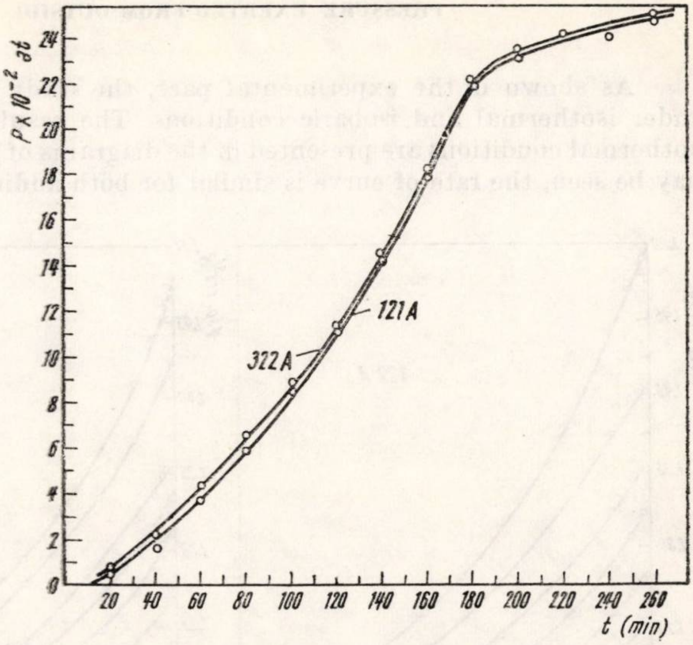

Fig. 2. — Variation of the polyethylene pressure with time during melting without outside action.

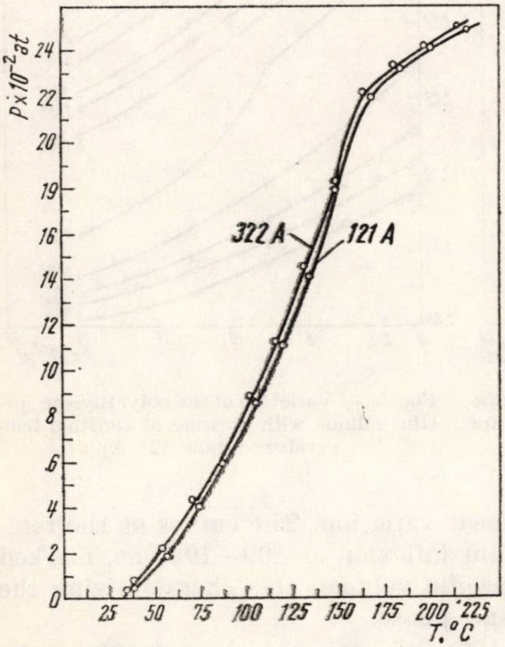

Fig. 3. — Variation of the polyethylene pressure with temperature during melting without outside action.

THE VARIATION OF THE SPECIFIC VOLUME UNDER THE EFFECT OF HYDROSTATIC PRESSURE EXERTED FROM OUTSIDE

As shown in the experimental part, the study has been performed under isothermal and isobaric conditions. The results obtained under isothermal conditions are presented in the diagrams of Figures 4 and 5. As may be seen, the rate of curve is similar for both additive-containing grades and is characterized by a nonlinear variation. The curves at the temperature of 130° present an important inflexion at 800–1000 at, marked by a sudden diminishing of the specific volume, this characterizing the complete melting of the crystalline phase.

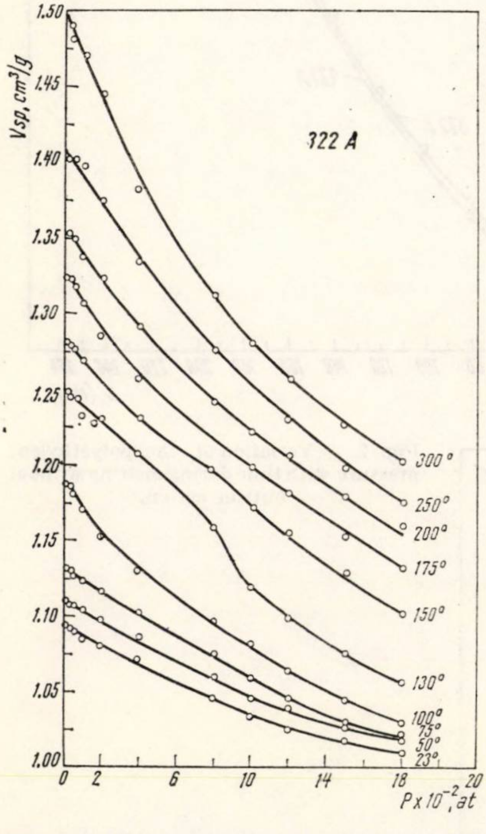

Fig. 4. — Variation of the polyethylene specific volume with pressure at constant temperature (grade 322 A).

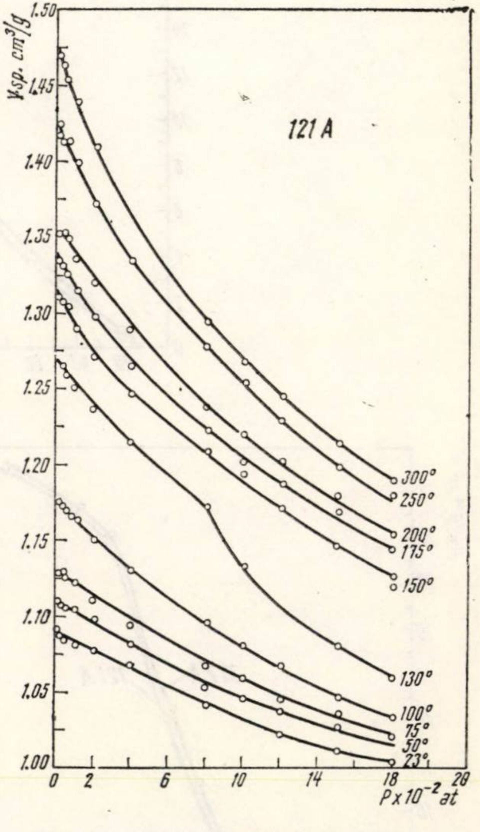

Fig. 5. — Variation of the polyethylene specific volume with pressure at constant temperature (grade 121 A).

At temperatures higher than 130° and pressures above 1 000 at, the specific volume of the melt tends to diminish nearly linear as the pressure increases.

The results obtained under isobaric conditions are represented in Figures 6 and 7.

Under these conditions too, the general rate of the curves is the same for both grades.

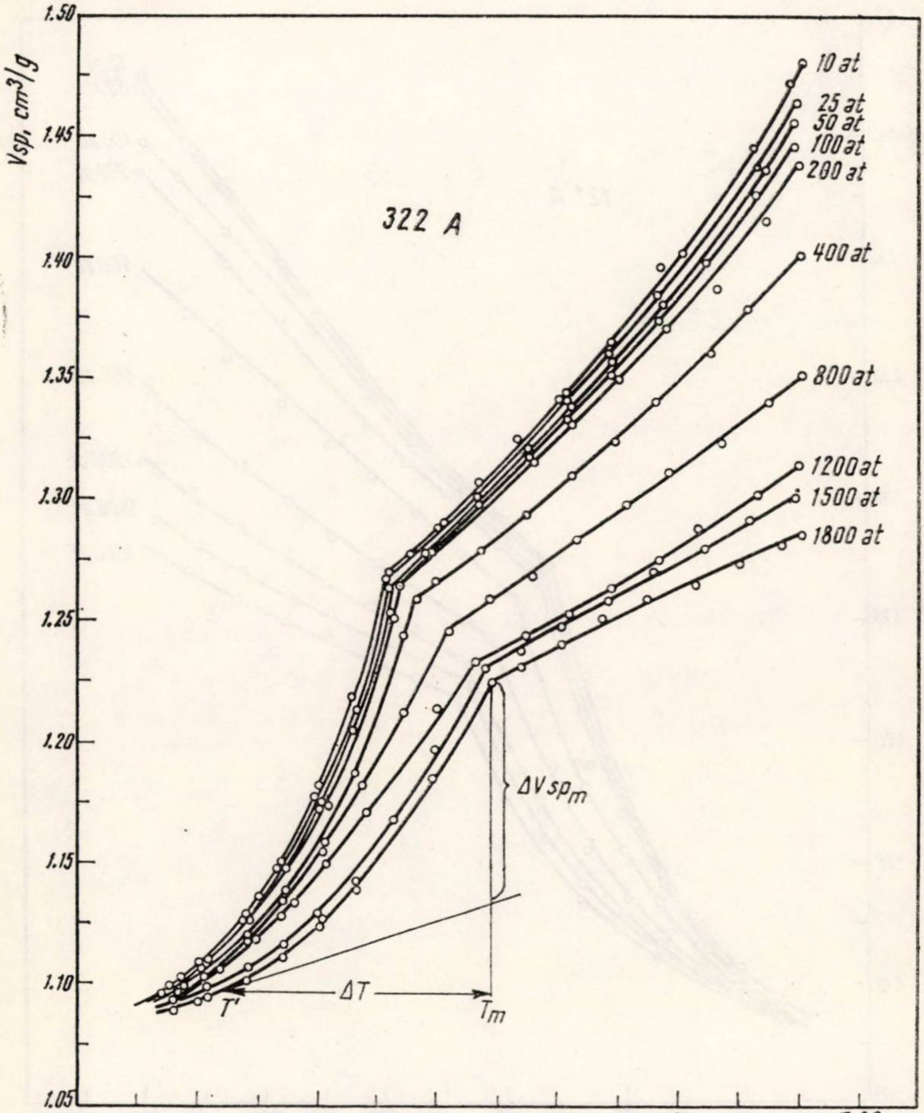

Fig. 6. — Variation of the polyethylene specific volume with temperatures at constant pressure (grade 322 A).

If the curves in Figure 6 are considered, and their slope is compared, calculated from the tangent of the angle made by the linear portion with a parallel to the abscissa represented in Table 3, it is found that it decreases from a value of about 11 for the pressure of 10 at to 5.2 (4.4) for 180 at, that is: as the pressure is increased, the slope of the isobaric curves diminishes.

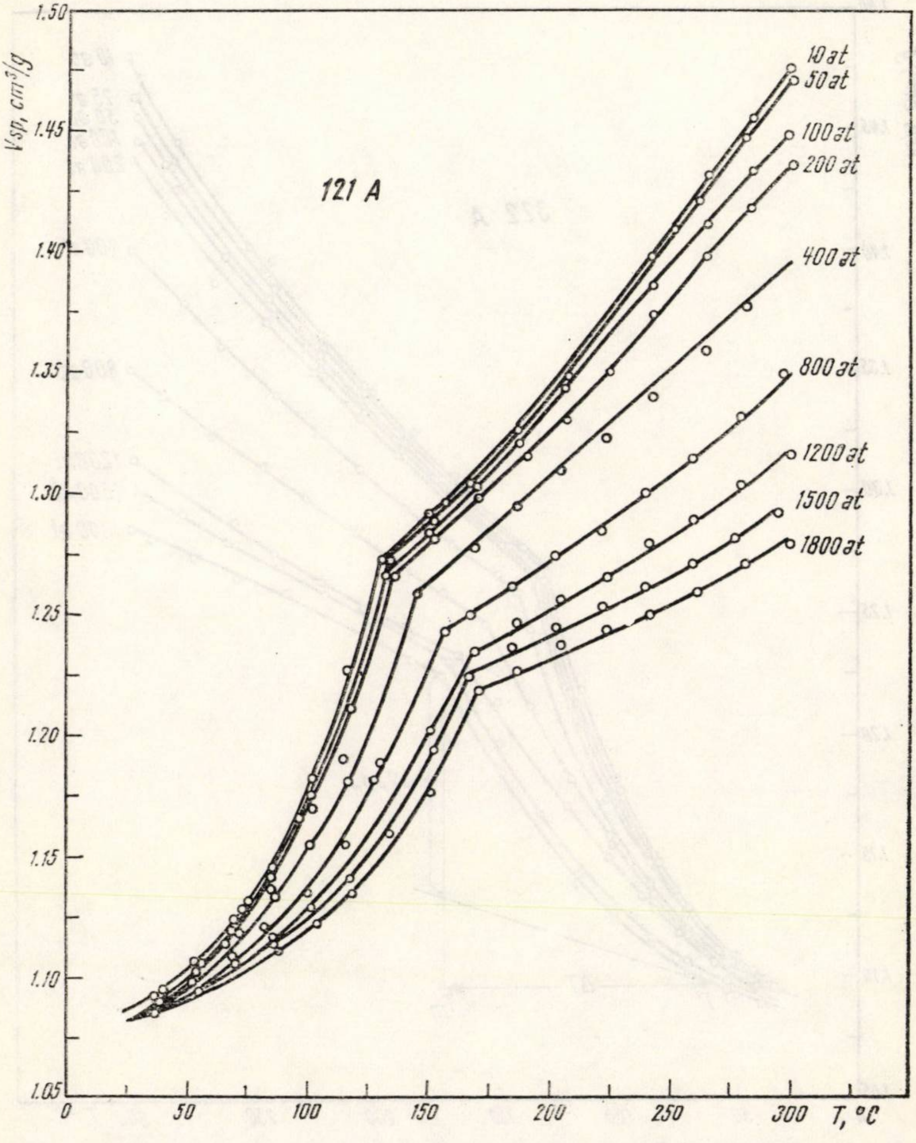

Fig. 7. — Variation of the polyethylene specific volume with temperature at constant pressure (trade 121 A).

This is explained by the forcing of chains to approach each other, giving the possibility of creating interchain cohesive forces with a specific molecular attraction of 1 kcal/mol, which by partially annihialating the effect of temperature lead to the pressure induced crystallization.

From Table 3 it also results that the additives increase the slope of the lines in comparison with the slope of lines obtained with the same grades but without additive. [1] This increase corresponds to greater specific volumes in additive-containing polymers, owing to the partial volatilization of the antioxidants and sliding agents.

Table 3

The slope of the line $(\partial V/\partial T)_p$ in the linear zone as a function of pressure

Pressure (P) at	Slope of line × 10^4	
	322 A*)	121 A**)
10	11.7	11.8
25	12.0	11.5
50	11.2	11.2
100	11.0	10.8
200	10.4	10.0
400	8.8	9.4

1200	6.0	5.8
1500	5.8	5.4
1800	5.2	4.4

*) Data in Figure 6.
**) Data in Figure 7.

In grade 322, the slope of the curves is somewhat greater owing to higher volatilization of the sliding agent.

At the same time as the increase of pressure, a rise of the melting temperature (T_m) is established, as can be seen from Figure 8.

The rise of the melting temperature, considered at the point where the sudden change of volume occurs, has a linear behaviour only up to 1200 at, above this value being established a tendency of approaching of the lines and of their remaining on the same level of about 170°.

This is due to the additives which by the fact that they interpose themselves between the chains, weaken the Van der Waals forces, increasing the rate of melting.

The linear variation of the melting point with pressure may be expressed by a simple empirical relationship of the form :

$$T = a + b \,.\, P \tag{1}$$

wherein the a and b coefficients have the values 130 and 0.0320 for the PE grade 121 A and 127.8 and, respectively, 0.0321 for grade 322 A.

It was been calculated from Fig. 8 that T_m increases in the linear zone with 3.2×10^{-2}°/at for grade 322 A and with 3.5×10^{-2}°/at for grade 121 A. This rate of melting point rises with the pressure in additive-containing polymers is about 0.7 to 1×10^{-2}°/at higher than that of the corresponding polymers without additive,[1] this being explained by the presence of the additives which facilitate the melting process.

The rise in temperature T_m in polyethylene ROPOL with the pressure within the range of 10 to 1200 at is in good concordance with the data

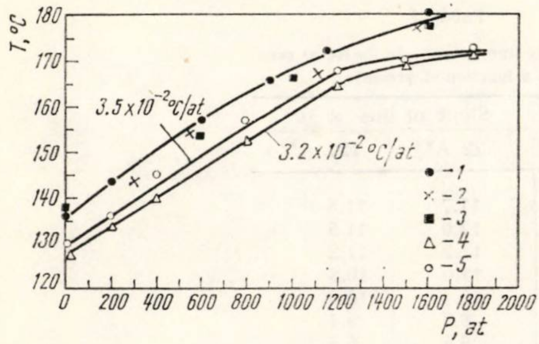

Fig. 8. – Plot melting point *vs.* presure.

1, Baer [32]: *2*, Matsuoka[49] *3*, Huseby[17]: *4*, Polyethylene 322A: *5*, Polyethylene 121 A;

of E. Baer and of L. Kardos [32] and is with 0,012 to 0.015°/at higher than the values obtained in [26,29] and[47,48].

The volume of the melt in type ROPOL PE (ΔV_{sp_m}) has been determined on the graph (Figures 6 and 7) by the difference between the volume of the melt at the temperature T_m at the beginning of the linear portion of the isobar and the volume of solid PE extrapolated at T_m. The interval of temperature between T_m and T' has been considered as in other similar works[10], as the melting interval (ΔT) of PE at the considered pressure.

The values T', T_m, ΔT and ΔV_{sp_m} are given in Table 4.

Table 4

The effect of pressure upon the extending of the melting interval and the melt volume

Polyethylene grade	Pressure (*P*), at	T_m, °C	T′, °C	ΔT, °C	$\Delta V_{sp_m} \times 10^2$ cc/g

[47] W. Parks and R. B. Richards, *Trans. Faraday Soc.*, **45**, 203 (1949).

[48] C. E. Weir, *J. Res. Nat. Bur. Stand.*, **53**, 245 (1954).

When analysing these data, it can be observed that as pressure increases, a widening of the interval of melting (ΔT) and a rise of the melting temperature (T_m) occur.

At the same time a diminishing of the volume of the melt (ΔV_{sp_m}) occurs.

These phenomena are similar to those already observed [10,32,49] in polyethylene and other polymers, but with the difference, in comparison to the mentioned researches, that in the ROPOL PE the interval of melting is situated in a higher range of temperature. The average molecular weight (within the range $32 \cdot 10^3$ to $43 \cdot 10^3$) does not sensibly influence the interval (ΔT) nor the volume of the melt (ΔV_{sp_m}) under the conditions of the present work.

It has been suggested [32,50] that these phenomena could be attributed to the polydispersion of the molecular weights of PE as well as to the relaxation phenomena occurring in the crystalline polymer before melting.

THE VARIATION OF THE COEFFICIENTS OF THERMAL EXPANSION AND ISOTHERMAL COMPRESSIBILITY

The variation of the specific volume of high-pressure PE with the temperature at constant pressure being known, the coefficient of thermal expansion (α) has been calculated, utilizing the curve $V_{sp} = f(T)$, at the pressure $P = 100$ at.

The obtained results are presented in Table 5.

Table 5

The variation of the coefficient of thermal expansion α(°C^{-1}) with the temperature*

Polyethylene grade	αX 10^4							
	Temperature, °C							
	50	75	100	130	150	200	250	300
322 A	6.41	8.1	10.8	12.1	14.1	12.92	12.56	12.7
121 A	6.12	7.95	11.2	13.2	14.9	13.5	13.1	13.0

* Calculated from the curve $V_{sp} = f(T)$ at $P = 100$ at (figs. 6and 7).

Up to the temperature range of 130° to 150°, corresponding to the melting zone, the coefficient of thermal expansion increases with the temperature. Above the melting range, the coefficient remains practically constant in the interval 12—13°, $^{-1}$, this showing that the temperature exerts a relatively little influence upon the coefficient of thermal expansion in PE in the melted state.

---

[49] S. Matsuoka, *J. Polymer Sci.*, **57**, 569 (1962).
[50] M. Takayanagi, *Mem. Fac. Eng. Kyushu Univ.*, **23**, 72 (1963).

Further, the compressibility expressed by the coefficient of isothermal compressibility (β_T) has also been calculated by the relative variation of the total specific volume with pressure.

From the specific data volume-pressure-temperature, under constant temperature conditions, the relative variation of the volume with pressure was calculated, tracing the curves of compressibility of Matsuoka type.[51]

$$(\Delta V/V_{23^\circ})_T = f(P)$$

shown in Figures 9 and 10.

By analysis of the curves presented in these figures, it will be seen that in the additive-containing polyethylenes (322 A and 121 A), the variation of the volume $(\Delta V/V_{23^\circ})_T$ takes place with a much slower rate than in the case of polyethylenes of the same type containing no additive.[1]. Thus, for example, in Table 6 limit values of the ratio $(\Delta V/V_{23^\circ})_T$ at 1800 at and different temperatures are given for the grades with and without additive.

Table 6

The variations of the ratio $\Delta V/V_{23^\circ}$ with temperature at the pressure of 1800 at

P at	T, °C	$(\Delta V/V_{23^\circ})\times 10^{-2}$			
		Polyethylenewithout additives		Additive-containing polyethylene	
		322 N	121 N	322 A	121 A
1800	23	6.12	6.35	7.60	7.70
	50	7.10	6.80	8.45	8.70
	75	7.70	7.90	10.10	9.80
	100	10.10	10.30	14.30	13.60
	150	11.20	12.80	17.70	16.80
	200	14.00	14.15	—	20.55
	250	16.10	16.75	21.10	26.75
	300	19.70	20.00	26.80	30.75

Remarks The data in the columns 3 and 4 are from our prior work,[1] The data from tne columns 5 and 6 are represented in the Figures 9 and lo,

From this table, it will be observed that the values obtained for the additive-containing PE are always higher than those for the polymer without additive and the difference is higher as the temperature is nearer to 300°. This means that the additives exert an influence upon the compressibility of the polymer and namely the compressibility of the additive-containing PE is always higher than that of the polymer without additive, as a consequence — probably — of the influence exerted by the sliding and plasticizing agent which facilitates the sliding and rearrangement of the chains. The fact will be noted that in additive-containing PE there has no more been observed in the evalution of the ratio $(\Delta V/V_{23^\circ})_T$ the sudden changes in the slope, within the range 150—175°, as is the case in similar grades without additive. This could explained in that the process of crystal-

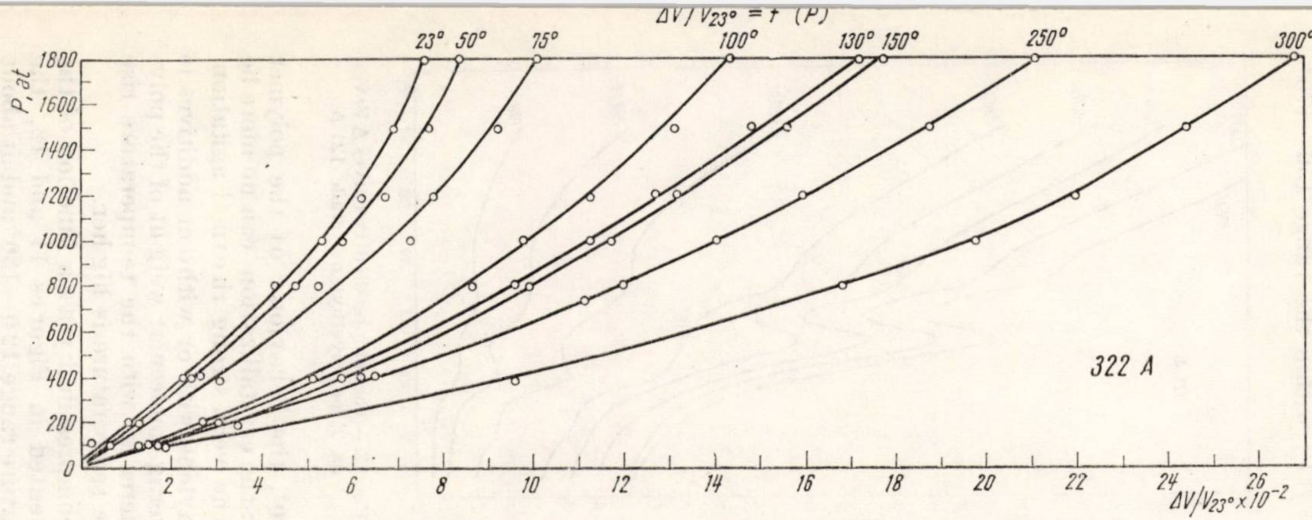

Fig. 9. — The compressibility curves $\Delta V/V_{23°}$ *vs* *P* according to Matsuoka [51] (grade 322 A)

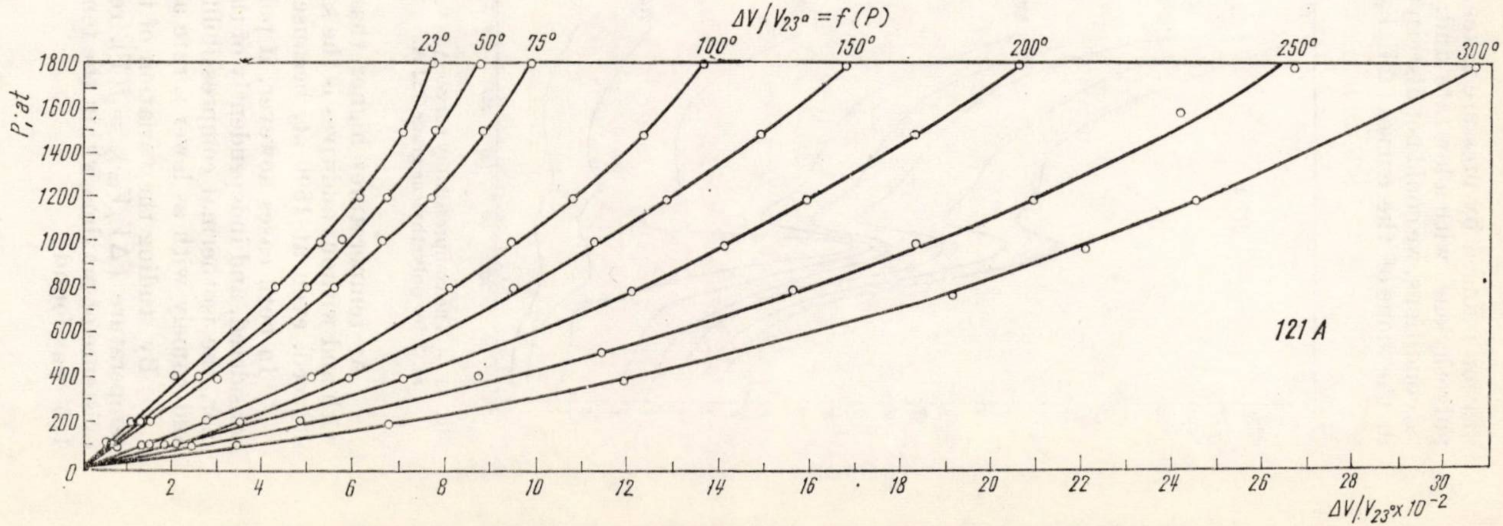

Fig. 10. — The compressibility curves Δ $V/V_{23°}$ *sv.* *P.* according to Matsuoka [15] (grade 121 A).

lization induced by pressure takes place, in the case of additive-containing polyethylene, with a low rate and, therefore, at least under our experimental conditions, we could not discern the jump, respectively the sudden change in the slope of the curves $(\Delta V/V_{23^\circ})_T = f(P)$ within the range 150—175°.

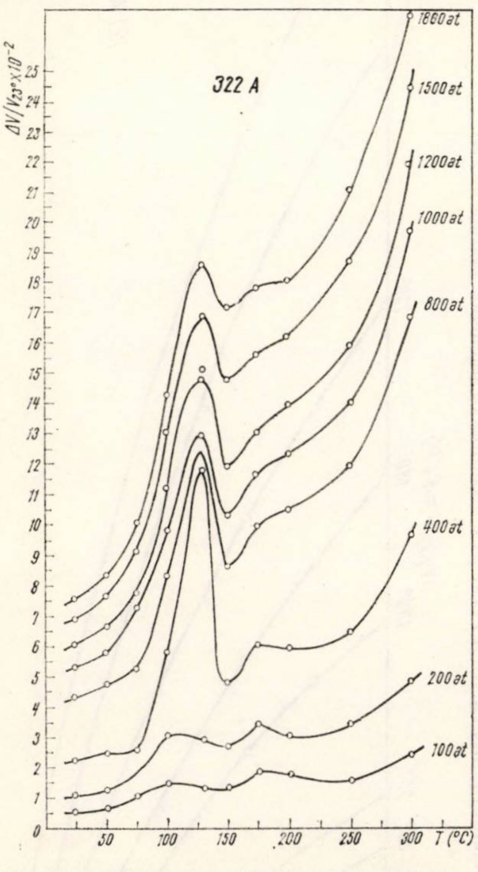

Fig. 11. — The compressibility curves $\Delta V/V_{23^\circ}$ *vs.* T for polyethylene grade 322 A.

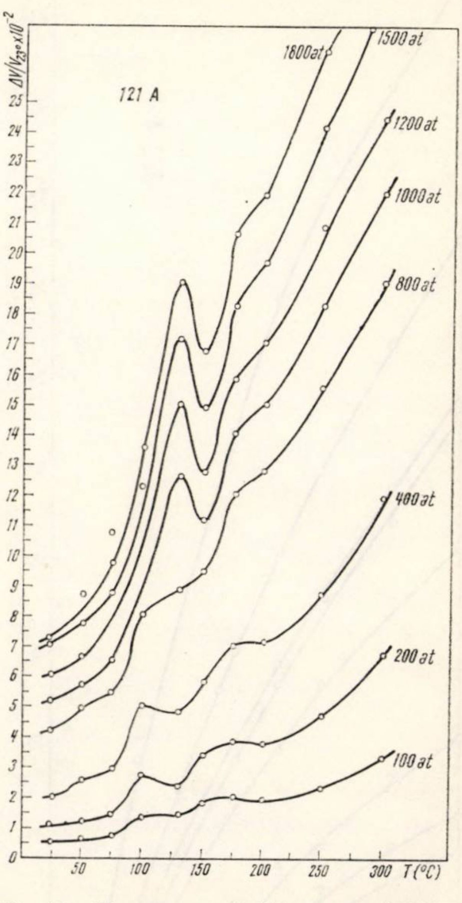

Fig. 12. — The compressibility curves $\Delta V/V_{23^\circ}$ *vs.* T for polyethylene grade 121 A.

At temperatures higher than 200°, the behaviour of the polymer with and without additives is the same : the crystallization can no more be induced, even at 1800 at, because of the very strong thermal agitation.

In both cases however, if polyethylene with or without additives is considered, and independently of the average molecular weight of the polymer, the isothermal compressibility increases with the temperature rise and namely with as lower a rate as the temperature is higher.

By studing the variation of the compressibility as a function of the temperature $(\Delta V/V_{23^\circ})_P = f(T)$, represented in Figures 11 and 12, the existence of maxima within the temperature range 120—130° and at about 175° was found.

The maxima at 130° appear at 100 at and grown in height with increasing pressure within the studied range. The heights of the maxima do not differ much for the two grades of PE especially at pressure higher than 800 at. This similarity can be explained according to [52] by the degrees of crystallinity being very little differentiated one from another, which is experimentally verified, as will be shown later on.

At 175°, the second maximum of compressibility appears at 100 at too, but its height gradually diminishes up to 1 000 at, after which it practically disappears.

The existence of a second maximum at 175° can be explained by the apparition of supercrystalline structure having high melting point, determined by the process of crystallization induced by pressure and by existence in PE of *alien* crystallization centres (the additives). These structures determine the appearance of the second phase transition.

From the experimental data pressure-volume-temperature, with the aid of the known relationship (2) : [1]

$$\beta_T = -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_T \tag{2}$$

the coefficient of isothermal compressibility (β_T) has been calculated, the variation with temperature of which is represented in Figures 13 and 14.

It is found that the value (β_T) is increasing with temperature and attains a maximum at approximately 130—150° corresponding to the rapid melting of the crystalline phase, after which the compressibility increases slowly with temperature at $P \geqslant 800$ at.

In grade 322 A (Fig. 13), with a lower average molecular weight, the compressibility is more rapid within a narrower temperature range too than in the grade 121 A, the molecular weight of which is higher with about 10^4 than that of PE 322 A. The existence of a second maximum of compressibility at $P \leqslant 400$ at and temperature of about 175° is also to be noted, which is probably due — as already shown — to the presence of supercrystalline structures generated by the presence of additives (antiblocking agents). The decrease of (β_T) with increasing pressure must be pointed out, due to the diminishing of interchain distances, respectively of the free volume,with the tendency of arrangement of the macromolecules in the melt when only their compression is achieved, this permitting the crystallization of the polymer at high temperature.

At pressures above 400 at, it may be estimated that β_T presents (within the range 150—300°) an approximately linear increase with temperature as in PE without additives [1], at pressures $P \geqslant 800$ at.

---

[52] M. M. MARTYNYUK and V. K. SEMENCHENKO, *Kolloid. Zhur.*, **25**, 190 (1963).

As can be seen by comparison of the diagrams in Figures 11–12 with those in Figs. 13–14, the two maxima with the transition range 130–150°, respectively 175, found at the variation of the ratio $(\Delta V/V_{23°})_P = f(T)$ will be also found in the case of the variation of β_T with the temperature.

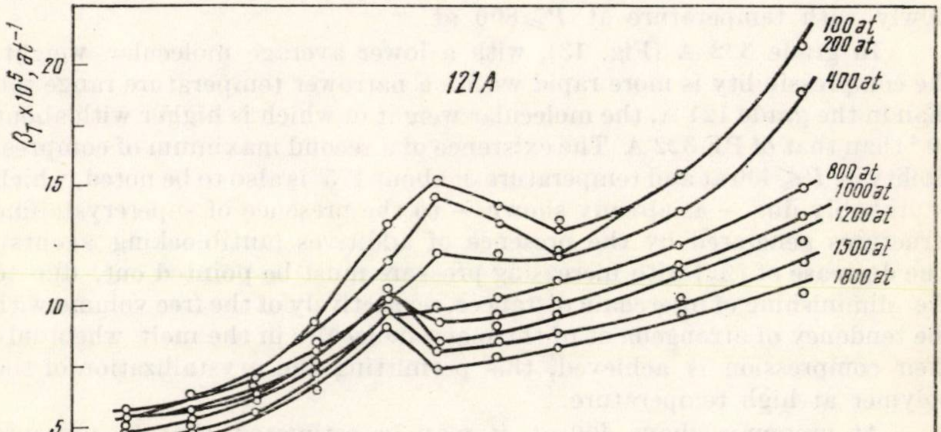

Fig.14. – Plot of the polyethylene compressibility variation *vs.* temperature at constant pressure, both for the solid and liquid phase (grade 121 A).

THE VARIATION OF THE DEGREE OF CRYSTALLINITY WITH TEMPERATURE AND PRESSURE

The compression moulding of the two PE grades under isothermal and isobaric conditions reported in Table 7 results in the arrangement of the macromolecular chains and their compaction, with the partial inducing of PE nucleating and crystallization.

Table 7

The variation of the degree of crystallinity with pressure and temperature

P at	*T* °C	322A		121 A		*T* °C	*P* at	322 A		121 A	
		d_4	X, %	d_4^{25}	X, %			d_4^{24}	X, %	d_4^{25}	X, %
			isobaric conditions					isothermal conditions			
10		0.9257	60.6	0.9250	60.2	23		0.9273	62.1	0.9282	62.7
25		0.9254	60.4	0.9253	60.1	50		0.9282	62.7	0.9279	62.4
50		0.9260	60.9	0.9247	59.9	75		0.9282	62.7	0.9308	64.9
100	300	0.9261	61.0	0.9263	61.2	100	1800	0.9291	63.5	0.9292	63.6
200	↑	0.9260	60.9	0.9285	63.4	130	↑	0.9285	63.0	0.9288	63.3
400	23	0.9263	61.2	0.9257	60.6	150	10	0.9280	62.8	0.9272	62.0
800		0.9265	61.3	0.9260	60.9	175		0.9266	61.4	0.9265	61.3
1200		0.9258	60.7	0.9259	60.8	200		0.9262	61.1	0.9265	61.3
1500		0.9261	61.0	0.9256	60.0	250		0.9262	61.1	0.9265	61.3
1800		0.9262	61.1	0.9256	60.6	300		0.9265	61.0	0.9262	61.1

The consequence of these structural changes is the increase of density. From the values of the density determined at 25° on PE specimens compression moulded under isothermal or isobaric conditions (Figures 4–5, respectively 6–7), and then cooled to 25° under the maximum pressure corresponding to each isobar or isotherm, the V_{sp} was calculated and on its basis the total degree of crystallinity (X) was deduced, expressed in percentages according to the known relationship (3):

$$X = (V_{sp} - V_a)/(V_{cr} - V_a) \tag{3}$$

wherein

V_{sp} = total specific volume
V_a = specific volume of the 100% amorphous phase
V_{cr} = specific volume of the 100% crystalline phase

From the results presented in Table 7, it can be seen that the degree of crystallinity of both PE grades increases both after the isobaric treatment and after the isothermal treatment in comparison with that of the initial material. The degree of crystallinity increases however, relatively, very little within the studied limits of the temperature and pressure ranges. This behaviour has been noticed in low pressure PE too even at pressures above 2 000. at [38,53]

---

[53] S. Matsuoka, *J. Appl. Polymer Sci.*, **4**, 115 (1960).

Thus in the isothermally treated polymers X increases from about 28% at 23° to 63.0–63.6% at 100–130° and then decreases to 61% at 300°. Both grades present a maximum at 130° within the limits of experimental errors.

The increase of the degree of crystallinity up to 130° is owed to the increase of the nucleating rate under the influence of the high hydrostatic pressure.

The heating and cooling of the polymer under pressure, near the melting point, allows the reorganization of the initial fold of the crystalline chain into a fold with greater length.

The increase of the degree of crystallinity much above 60% is however not possible, because of the great number of $-CH_3$ groups in the chains, which hinder their arrangement and compaction, even if the time of maintaining the specimen at the equilibrium is prolonged 6 times, as it has been shown in the experimental part (Table 2).

To this, the length of the chain brings its contribution too, respectively the molecular weight of PE which, being not high enough, puts a limit to the increase of the crystal size in the chain direction. The total degree of crystallinity (X) does not show differences between the two polymer grades, although the 121 A grade contain only an antioxidant in a large amount, and the 322 A contains, besides a little antioxidant, a sliding agent and an antiblocking agent too.

The differences that have been previously established undoubtedly result from the fineness of the crystalline structure, coming from the dimensions, number and perfection of the spherulites, which are forming during crystallization and post-crystallization.

The antiblocking agent increases the number of nucleating centres during crystallization, and the small amounts of sliding agent increases the number of nucleating centres during post-crystallization.

In isobar treated PE, the increase in crystallinity (measured after traversing the temperature range 23 to 300 at different constant pressures within the range of 10 to 1800 at) (Table 7) is somewhat lower than in the case of isothermal treated PE and is comprised within the same order of magnitude of about 60%. This behaviour is normal, taking into account that under isobaric conditions the thermal equilibrium has not been reached.

CONCLUSION

The high-pressure additive-containing polyethylenes present in comparison to the same grades without additives a similar behaviour from the point of view of the volume-pressure-temperature relationship, this leading at first sight to the conclusion that the used additives do not cause any essential change in the structural properties.

Although the rate of the curves is approximately the same, the values V_{sp}, β_T and α in the grades with additives are in general somewhat higher than those in the grades without additives, due to the influence of the additives.

The sliding and antiblocking agents exert a greater influence upon the additive-containing polymers than the antioxidant. The antiblocking agent (SiO_2) increases the number of nucleating centres during crystallization, and the sliding agent increases the number of nucleating centres during post-crystallization, this explaining why the 322 A grade presents a relatively higher increase of the degree of crystallinity as against the 322 grade without additive, in comparison with the 121 A grade, under the same temperature, pressure and time conditions, as can be seen in Table 8.

Table 8

Comparison of the average degree of crystallinity in polyethylene with and without additives

PE grade	Degree of crystallinity (X), %				
	initial	after isobaric treatment		after isothermal treatment	
		Polymer without additive	Additive-containing polymer	Polymer without additive	Additive-containing polymer
322	28.0	59.9	60.9	60.5	62.2
121	27.8	60.5	60.8	61.2	62.5

Note: The values in columns 3 and 5 represent the arithmetic mean of the data obtained in our prior work [1]. The values in columns 4 and 6 represent the arithmetic mean of the data comprised in Table 7 of the present work.

The presented conclusions have immediate practical consequences, namely:

At high pressure (750 to 1 000 at) the temperature interval between 130 and 175° constitutes the optimum range for achieving pressure induced crystallization with the attaining of a higher or lower degree of crystallinity, according to the working conditions.

Above 180°, it is no more possible to induce crystallization, as high as the hydrostatic pressures is raised.

Pressure-induced crystallization, postcrystallization, surfusion, cooling rate and the contraction of the finished product impose a rigorous temperature control, the making of judiciously designed moulds and the strict observing of the temperature and pressure history, the more so when a high quality level and least variation of dimensional properties are required. From the interplay of these parameters, the necessary conditions can be created to turn to profit one or the other of the desired properties.

The stirring and [illegible] of complete [illegible] from the [illegible]. The [illegible] increases the number of [illegible] centres during crystallization, and the [illegible] increases the number of [illegible] centres during [illegible] crystallization, [illegible] a more [illegible] degree, [illegible] the [illegible] under the same temperature, pressure and [illegible] (Table 2).

TABLE 2

[illegible]

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
22	250	560	55.9	60.3	62.3
[illegible]	375	565	60.8	61.2	62.5

[illegible]

The present conclusions have immediate practical consequences, namely:

a) High pressure (750 to 1 000 at) the temperature interval between 650 and 670 constitutes the optimum range for achieving pressure induced crystallization with the obtaining of a higher or lower degree of crystallization, according to the working conditions.

b) About 1000, it is no more possible to induce recrystallization, as high as the hydrostatic pressure is raised.

c) Besides [illegible] crystallization, [illegible] recrystallization, the [illegible] cooling rate and the contraction of the finished product impose a rigorous temperature control, the making of judiciously designed moulds and the strict observing of the temperature and pressure history, the more so when a high quality level and a set variation of dimensional properties are required. From the interplay of these parameters, the necessary conditions can be selected to favour one or the other of the desired properties.

ZERO CURRENT BIPOTENTIOMETRIC INDICATION WITH PRETREATED ELECTRODES. I

OXIDIMETRIC TITRATION OF Fe(II) USING PLATINUM ELECTRODES

L. KÉKEDY* and F. MAKKAY **

* Department of Analytical Chemistry "Babeş-Bolyai" University,
Str. Arany J. 11, Cluj, Romania

** Central Institute for Training Teaching Staff, "Babeş-Bolyai" University, Cluj, Romania

Received July 29, 1972

Details are presented concerning the new zero current bipotentiometric indication with differently pretreated platinum electrodes of the Fe(II) titration with oxidants ($Ce(SO_4)_2$, $K_2Cr_2O_7$ and $KMnO_4$).

The role of the surface state of the solid indicator electrodes in many electroanalytical techniques is well recognized now, e.g. in potentiometry, bipotentiometry, polarography, coulometry, amperometry, biamperometry and chronopotentiometry.[1,2] In an early short communication[3] we have reported on a new bipotentiometric indication technique, called zero current bipotentiometry, based on the determination of the potential difference setting in during a titration between two identical but differently pretreated indicator electrodes. The potential difference appears owing to differences in kinetic parameters (reversibility) of the respective electrode reactions, i.e. to differences in the rates with which the dissimilar electrodes approach equilibrium. The potential difference will show a sudden change at the end point allowing its location. The purpose of this paper and of some other following ones is to present details concerning the performance of this method in the case of different titration systems. At present the performance characteristics of the redox titration of Fe(II) with the most common oxidants,[4] $Ce(SO_4)_2$, $K_2Cr_2O_7$, $KMnO_4$, are reported.

EXPERIMENTAL

A conventional potentiometric titration assembly was used consisting of a tall beaker of 50 ml, a 10 ml semi-microburret and an electromagnetic stirrer. Two identical rectangular platinum indicator electrodes were used with an apparent geometric area of 0.93 cm^2 each. The platinum electrodes were connected directly to the RADIOMETER Type TTT1 pH-meter which served as a potential measuring device. The very small current drain of the apparatus, 10^{-12} A, is negligible as far as its polarizing effect is concerned. Before use, the platinum electrodes were subjected to the pretreatment procedures indicated in our previous paper. [1] For replicate titrations the following pretreatment procedure was chosen. Both electrodes were subjected for 1 minute to an anodic-cathodic cyclization in 1N H_2SO_4 using 2 VA.C. from the mains, in order to eliminate the adsorbed impurities. After that, one of the electrodes was dipped in KI to obtain a bare surface, the other (always the same) was heated for a short time in natural methane gas flame. The titration curves of the potential difference between the platinum electrodes vs. volume of the titrant added were recorded in the usual way. 5 ml 0.01 N $FeSO_4$ diluted to 30 ml with 1N H_2SO_4 were titrated with 0.01 N $Ce(SO_4)_2$, $K_2Cr_2O_7$ or $KMnO_4$. Analytical grade chemicals and doubly distilled water were used.

RESULTS AND DISCUSSION

First of all different pretreatment combinations were investigated in order to select the most suitable electrode pair for routine work. It has been found that the shape of the zero current bipotentiometric titration curves depends on the titrant used as well as on the pretreatments applied to the electrodes. Some representative curves are shown in Fig. 1. One can see that the same electrode pair exhibited completely different titration curves according to the titrant used (curves *A*, *B*, *C*) in spite of the fact that in all cases the same redox system, Fe(III)/Fe(II), was present before the e.p. This fact emphasizes newly that the surface state of the electrodes depends on the nature of the adsorbed ions too, in this case on the reduced formes of the titrants used, namely Ce(III), Cr(III) and Mn(II), respectively. Using the same titrant but different pretreatment combinations, completely different titration curves have been obtained (compare curves *A* and *D* or *B* and *E*, respectively), accentuating the role of the oxidation state of the platinum surface. It is apparent from Fig. 1. that the bipotentiometric titration curves can be divided, according to their shape, into three categories : first derivative curves, second derivative curves of an usual potentiometric titration curve and/or some intermediate forms. Their appearance has been explained earlier. [3]

From all the titrations performed, the following can be concluded : 1) The shape of both potentiometric and bipotentiometric titration curves differs according to the pretreatments applied as well as the electrode pair combination used. 2) The potentiometric equivalence values showed slight oscillations depending on the pretreatment as well as on the titrant used. The oscillations were smaller in the case of titrations with dichromate (number of titrations $n = 34$, variance $s^2 = 0.0010$) and were slightly greater using $KMnO_4$ as titrant ($n = 28$, $s^2 = 0.0022$). As expected, the bipotentiometric equivalence volumes showed smaller fluctuations ($n = 17$ and

$s^2 = 0.0004$ in the case of dichromate, and $n = 14$, $s^2 = 0.0011$ in the case of $KMnO_4$) than the potentiometric ones. 3) Using dichromate as titrant, the mean of equivalence volumes obtained potentiometrically was equal with the bipotentiometric mean, $\overline{v} = 4.52$ ml. Titrating with $KMnO_4$, the potentiometric mean, $\overline{v} = 4.52$ ml, differed slightly from the bipotentiometric one ($\overline{v} = 4.54$ ml). 4) The potential break near the e.p. $(\Delta E)_{\pm 10\%}$ also varies with the pretreatment. Using $KMnO_4$, this break was always smaller than by titrating with $K_2Cr_2O_7$. 5) In order to obtain well-shaped bipotentiometric signals, one of the electrodes must be more reversible than the other. 6) At the beginning, the indicator electrodes were immersed in the Fe(II) solution. As expected, the strong reducing medium has modified the initial surface state of the electrodes, reducing the oxide film on their surface. Consequently, before the e.p. the oxidized electrodes behaved like the reduced ones. 7) The equivalence signal and the shape of the titration curves are also determined by the action of the excess of titrant on the electrodes. The more different this action on each electrode is, the more pronounced will be the equivalence signal, a fact which depends on the pretreatment. In accordance with our earlier findings,[1] it was observed, this time too, that the bare electrode is easier oxidized than the previously reduced one. Therefore, making a choice of a proper electrode pair for a given titration, one must also take into account the possible action of both titrate and excess of titrant on the electrodes.

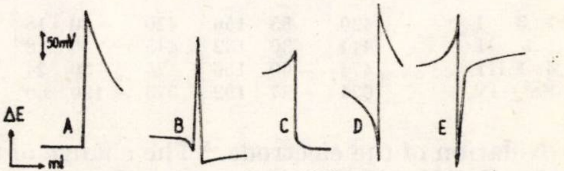

Fig. 1. — Zero current bipotentiometric titration curves of Fe (II) with different titrants using dissimilarly pretreated platinum electrode pairs.

Titrants: A) Ce (IV), B) $KMnO_4$, C) $K_2Cr_2O_7$. One electrode oxidized at + 1500 mV (vs. S.C.E.), the other reduced at − 300 mV. Titrant: D) Ce (IV), E) $KMnO_4$. One electrode was bare, the other reduced at − 300 mV.

In order to ascertain the most suitable pretreatment, the problems of time response and reproducibility of measurements have been also investigated. For this purpose, the potentials in 1N H_2SO_4 solutions containing different Fe(III) : Fe(II) ratios have been recorded as a function of time in stirred solutions. Some illustrative data are given in Table 1. ΔE and Δt represent the potential drift and, respectively, the time elapsed till the constant electrode potentials (E) have been obtained, after dipping the electrodes in the respective solutions. The reduced (R) and bare (B) electrodes are apparently free of surface oxides, the oxidized (O) and heated (H) ones are at least partially covered with oxide. The rest potentials observed on oxide-free surfaces are apparently identical (R I—III), (B I—II) but slower than those observed on oxidized surfaces (0 I—II), (H I—II). In the solution III all the surfaces investigated exhibited the same redox potential, owing rather to a strong Fe(III)-ion adsorption than to a surface

Table 1

Rest potentials of pretreated platinum electrodes (vs.S C.E.) in Fe(III)/Fe (II) solutions

Fe (III)/(II) ratio	Symbol	Pretreatments											
		Reduced (R)			Bare (B)			Oxidized (0)			Heated (H)		
		E mV	ΔE mV	Δt s	E mV	ΔE mV	Δt s	E mV	ΔE mV	Δt s	E mV	ΔE mV	Δt s
1 : 3	I	420	−55	156	420	−30	18	430	−115	180	433	−36	168
1 :1	II	444	−30	132	445	−40	18	460	−53	180	453	−36	168
3 : 1	III	474	−50	156	475	−30	24	472	−180	132	474	−35	120
Fe^{3+}	IV	624	+37	192	575	+120	60	665	−343	528	627	+27	84

oxidation of the electrode. [5] The change of the redox potential values with the Fe(III) : Fe(II) ratio generally corresponds to the theoretical value (28.2 mV) within the experimental errors, denoting that the redox potentials observed were equilibrium potentials (excepting of course solution IV). Nevertheless, on oxidized surfaces these changes were always significantly less, than the theoretical values and decreased with the increase of oxygen coverage of the electrodes. The observed potential values in this case were mixed potentials determined by the surface oxide layer

$$\mathrm{Pt} + 2\mathrm{H_2O} = \mathrm{Pt(OH)_2} + 2\mathrm{H^+} \qquad \mathrm{E_0} = 0.98\ \mathrm{V}.$$

According to Vetter, [6] the potentials of oxide electrodes with electron conducting oxide layers are given by the expression

$$E = \frac{\mathrm{d}\,[\Delta G\,(n)]}{2F\cdot \mathrm{d}n} - \frac{RT}{F}\ln a_{H^+} \tag{1}$$

where n represents the degree of oxidation of the electrode, and ΔG the free enthalpy of formation of the oxide. Consequently, if the degree of oxidation of the electrode varies continuously (at constant pH) during an experiment, E will vary similarly, according to the variation of $\Delta G(n)$. This is one of the causes of the potential drifts observed in oxidizing media. Inversely, the reduction of oxide film in reducing media will cause negative potential drifts. [7] The sign of the potential drifts reported in Table 1 has the same explanation.

It was to be expected that such potential drifts will appear during the bipotentiometric measurements too. Indeed, a slow stabilization of the potential difference has been observed at higher redox potentials, mainly if the electrodes used were poorly oxidized ones. The bipotentiometric technique is superior also from this point of view to the conventional potentiometry with one working electrode, the potential drift of the electrodes being partially compensated.

[7] C. B. Roy and S. C. Das, *Indian J. Chem.*, **8**, 833 (1970).

Other kinds of potential drifts were also observed. By stopping the stirring of the solution sometimes rapid potential increase took place. It has been proved that this phenomenon is due to the oxygen oxidation of Fe(II) ions on catalytically active electrode surfaces. Potential drifts of this kind never occurred in the absence of dissolved oxygen or Fe(II) ions, neither when both electrodes were reduced ones.

The most suitable electrode pair for routine work has been also investigated. For this purpose the electrode pretreatment procedure given in the experimental part was applied. Using the same electrode-pair combination, a great number of replicate titrations have been performed in order to test the reproducibility of the procedure. Although the same electrode pair was always used, different titration curves have been obtained in this case too, according to the titrant used. Using $Ce(SO_4)_2$ the curves were of B and D type (Fig. 1), the equivalence volumes being identified as the abscissa of a characteristic peak on the curve. Titrating with $K_2Cr_2O_7$ the titration curves were of *A* type (Fig. 1). With $KMnO_4$ *B* type curves have been obtained with very sharp peak, enabling us the exact location of the e.p. For comparison, usual potentiometric titration curves have been also registered, the e.p. being evaluated according to Hosteller and Roberts.[8] The comparative data are given in Table 2.

Table 2

Comparsion of potentiometric and bipotentiometric titration data

Method / Titrant	$Ce(SO_4)_2$		$K_2Cr_2O_7$		$KMnO_4$	
	n	$s^2 \cdot 10^6$	n	$s^2 \cdot 10^6$	n	$s^2 \cdot 10^6$
Potentiometric	14	152	12	327	8	77
Bipotentiometric	25	179	26	340	11	50

The electrode potentials observed were mixed potentials acquiring steady state values only after some time, when the sum of the currents of all cathodic processes equals to the sum of all anodic currents [9]

$$\sum k^0_{0x,i}\,[0x, i] \exp\left[\frac{-\alpha_i n_i F}{RT}\,E\right] = \sum k^0_{\text{red},i}\,[\text{red}, i] \exp\left[\frac{\beta_i n_i F}{RT} E\right] \quad (2)$$

The value of this constant potential is given by the equation

$$E = \frac{RT}{\sum \alpha_i n_i + \sum \beta_i n_i} \ln \frac{\sum k^0_{0x,i}}{\sum k^0_{\text{red},i}} + \frac{RT}{\sum \alpha_i n_i + \sum \beta_i n_i} \ln \frac{\sum[0x, i]}{\sum[\text{red}, i]} \quad (3)$$

[9] M. S. Zaharevskii, "Oxredmetriia", Leningrad, Himiia, 1967.

Equation (3) indicates that the value of the individual electrode potentials depends, besides the concentrations, also on the values of the rate constants (k^0) and the electrochemical transfer coefficients (α, β) of each cathodic and anodic process, being highly dependent on the surface state of the electrode. The fluctuations observed in the bipotentiometric equivalence values are mainly due to this phenomenon. Nevertheless, the bipotentiometric technique is superior to the usual potentiometric one, the time dependence of the potential values observed being less pronounced.

Non-equilibrium steady state of the mixed potentials have been observed by others too[10] at the potentiometric titration of Fe(II) with oxidants like $S_2O_8^{2-}$, H_2O_2 and $K_2Cr_2O_7$.

Using the above mentioned pretreatment procedure, Fe (II) solutions down to 10^{-3} molar concentrations could be titrated with good results.

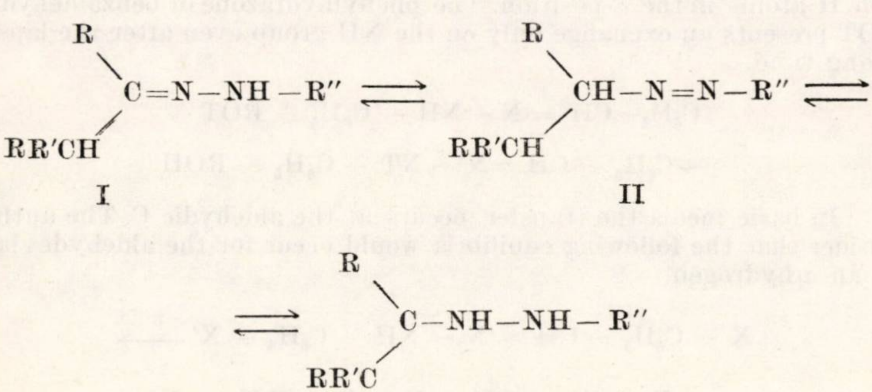
THE SYNTHESIS AND SPECTROPHOTOMETRIC STUDIES ON BENZOYL CYANIDE PHENYLHYDRAZONES

LUCIA BEU and JANA RUSSU
Institute of Chemical and Pharmaceutical Research
Str. Fabricii 126, Cluj, Romania

Received March 8, 1972

Some phenylhydrazones of benzoyl cyanide substituted with the acetyl group have been prepared and their dissociation and rate constants have been determined.

The most controversial problem about the structure of phenylhydrazones is that concerning their existence in normal form (I) or in two tautomer forms : azo (II) or enehydrazine form (III), respectively.[1]



I

II

III

The discussions especially dealt with O' Connor's [2–4] affirmation who considered these substances as existing only in the azo form. The doubts were generated by the existence of azo-peroxides (IV), which are obtained from the phenylhydrazones of aldehydes, and whose spectra are very similar to those of the compounds (II).

---

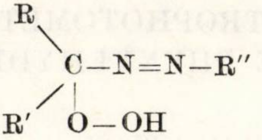
[2] R. O'Connor, *J. Org. Chem.*, **26**, 4375 (1961).
[3] R. O'Connor and W. Rosenbrook, *J. Org. Chem.*, **26**, 5208 (1961).
[4] R. O'Connor and G. Henderson, *Chem. and Ind.*, **1965**, 850.



IV (R′=H)

It has been shown that spectra of these substances recorded cautiously (fast and avoiding oxygen) are different from those recorded without special care. [5–7]

O'Connor's assumption, which assigns the yellow colour of the phenylhydrazone solutions in the presence of air to a mixture of azo-compounds (II), was strongly opposed by many authors. By means of spectrophotometry, [5,8,9] labelling,[10] polarography [11] and other methods it has been proved that the phenylhydrazones cannot exhibit tautomerism in neutral solution.

These facts are worth discussing as the results of the above mentioned workers were obtained in neutral solutions at room temperature. In more vigorous conditions, e. g. in acid or basic media, the equilibrium may vary favouring the azo form; the result obtained with one class of hydrazones should not be generalized to another class.

Studying various hydrazones, semicarbazones and oximes in *T* labelled ethanol solutions, Simon and Moldenhauer[10] have found by tritiating the C atoms that the II ⇌ I equilibrium is indicated in the case of aldehydes and a II ⇌ III equilibrium in the case of the aldehydes and ketones with H atoms in the α-position. The phenylhydrazone of benzaldehyde in EtOT presents an exchange only on the NH group even after the lapse of a long time.

$$C_6H_5{-}CH = N - NH - C_6H_5 + ROT \rightarrow$$

$$\rightarrow C_6H_5 - CH = N - NT - C_6H_5 + ROH$$

In basic media the transfer occurs at the aldehydic C. The authors consider that the following equilibria would occur for the aldehydes lacking an α-hydrogen.

$$X - C_6H_4 - CH = N - NH - C_6H_4 - X' \xrightarrow{-H^{(+)}}$$

$$\longrightarrow X{-}C_6H_4 - \overset{(-)}{C}H - N = N - C_6H_4 - X'$$

$$\upharpoonleft\!\downharpoonright$$

$$X - C_6H_4 - CH = N - \overset{(-)}{N} - C_6H_4 - X'$$

[11] L. Kitaev and T. Tropolskaya, *Doklady. Akad. Nauk. S.S.S.R.*, **1963**, 465.

The H→T exchange depends on the structure of the aldehyde and is largely proportional with the concentration of the base. The tritium appears in the aldehydic C atom and the transfer is mediated by the azo compound.

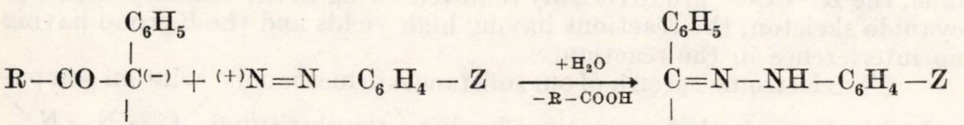
Yao and Resnik, [5,6] studying the spectra of phenylhydrazones of the above mentioned type, assign to these the band at 230−240 nm and a more intense one beyond 320 nm, and to the azo derivatives a maximum at 270−280 nm.

Iffland and co-workers [12] studying the spectra of di-, tri- and tetrasubstituted phenylhydrazones with the general formula :  ,

having at least one H atom on the carbon or nitrogen of the  chromophore, present, in the case of an aryl substitution on the final carbon or nitrogen atom, three absorption bands about 340 nm (maximum absorption), 300 nm (shoulder) and 230 nm (absorption of medium value). The difference between the spectra of the phenylhydrazone of benzaldehyde and that of the substituted compounds on the terminal C or N atom is minimal.

In our spectrophotometric studies we have investigated the trisubstituted phenylhydrazones of the $R_1R_2C{=}N{-}NH{-}C_6H_4{-}Z$ type, where $R_1{=}C_6H_5$; $R_2 = CN$; and $Z{=}H$, $CO{-}CH_3$ (*o*, *m*, *p*), as they possess an increased stability compared to the hydrazones used by Iffland [12] and, on the other hand, in order to establish a comparison between our compounds and those used by Iffland and Simon in their studies.

In order to obtain suitable compounds, we have prepared these phenylhydrazones by coupling the mono substituted diazonium salts with nitriles having an α-acylated methyne group :



$$R{-}CO{-}\underset{CN}{\overset{C_6H_5}{C^{(-)}}} + {}^{(+)}N{=}N{-}C_6H_4{-}Z \xrightarrow[-R-COOH]{+H_2O} \underset{CN}{\overset{C_6H_5}{C}}{=}N{-}NH{-}C_6H_4{-}Z$$

where

$Z{=}H$; $CO{-}CH_3$ (*o*, *m*, *p*) and $R{=}H$; CH_3 ; $CH_3{-}CH_2$;

$CH_3{-}CH{-}CH_3$; OC_2H_5 ; $COOC_2H_5$; C_6H_5 ; $CH_2 - C_6H_5$.

As the reactivity of the active methylene in benzyl cyanide is much reduced, the product cannot react directly with the diazonium salt and, therefore, the benzoyl cyanide phenylhydrazone (the only known compound in table 1) was prepared by the Japp-Klingemann reaction.[13-15] We used the same reaction, the methynic compound being the α-acyl benzyl cyanide. The results of the coupling reaction are summarized in table 1.

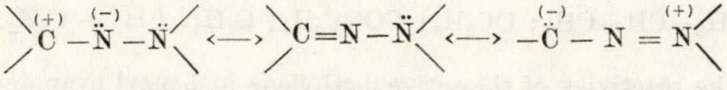
The splitting of R—CO— group, following a Japp-Klingemann reaction, was performed on eight acylated derivatives of benzyl cyanide, where R may be quite different. The splitting reaction, which may be also a decarboxylation ($R = COOC_2H_5$), develops spontaneously at room temperature at different pH values. In nine of these cases the azoic intermediate was isolated and we observed in all described reactions the same behaviour as in the case of α-acetyl benzyl cyanide, the same phenylhydrazone being isolated with very similar yields.

We may draw the conclusion that in the case of α-acetyl benzyl cyanide, the R—CO— group is easily removed owing to the stability of benzyl cyanide skeleton, the reactions having high yields and the R group having no interference in the reaction.

The electronic spectra of our substances in methanolic solution compared with those of other derivatives having a trisubstituted  chrompohore show a very high resemblance.

For the di- and trisubstituted hydrazones the chromophore may be represented as a hybrid having the following structure :



The compounds given in table 1 have unchanged spectra in methanol and acids. We shall try to establish the actual interaction between the nitro-

gen and the C=N group, as well as their dependence upon the aryl rest substitution. In fig. 1 the spectra of these substances in methanol : water are represented.

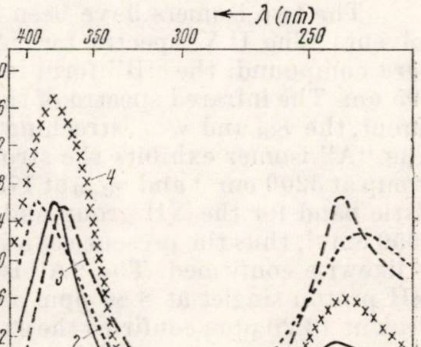

Fig. 1. — The U.V. spectra of benzoyl cyanide phenylhydrazones in $MeOH/H_2O$

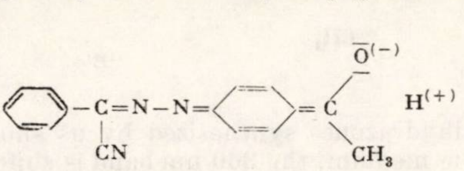
1, $C_6H_5-\underset{\underset{CN}{|}}{C}=N-NH-C_6H_4-Z$; Z=H *2*, Z=$o$-$COCH_3$

3, Z=m-$COCH_3$ *4*, Z=p-$COCH_3$

The *para* substitution ($Z=COCH_3$) exerts a bathochromic shift of the 360 nm band. This may be assigned to the electromer action of the $CO-CH_3$ rest, suggesting the following conjugated structure :



The *meta* derivative has no shoulder at 280 nm but the intensity of the 360 nm band is strongly decreased. The existence of two different *ortho* derivatives : one with m.p. 128–129° and another with m.p. 183–185 °, having different U.V., I.R. and N.M.R. spectra allow us to consider two geometric isomers "A" and "B".

Table 3

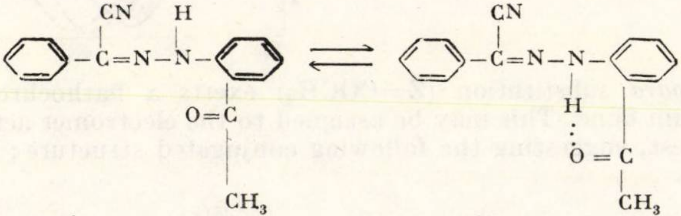
I.R. and N.M.R. spectra of phenylhydrazones $CN-C(C_6H_5)=N-NH-C_6H_4-Z$

$CN-\overset{C_6H_5}{\overset{|}{C}}=N-NH-C_6H_4-Z$

Z	I.R cm^{-1}					N.M.R. ppm	
	ν_{NH}	$\nu_{C=N}$	$\nu_{C=O}$	$\nu_{C=N}$	$\nu_{C=C/arom}$	$=N-NH$	$COCH_3$
H	3245 vs	2215 vs	—	1645 w	1605 vs	8.77	
o-$CO-CH_3$							
"A"	3200	2215 vs	1730 vs	1630 s	1580 s	8.80	2.68
"B"	—	2210 s	1650 s	1605 m	1580 s	13.20	2.70
m-$CO-CH_3$	3250 vs	2210 s	1680 vs	1610 s	1591 s	8.87	2.67
p-$CO-CH_3$	3245 s	2210 s	1720 vs	1615 s	1590 s	8.88	2.57

The two isomers have been isolated by crystallization from different solvents. The U.V. spectra for "A" form are very similar to those of the *para* compound, the "B" form having a weak maximum at 320 nm and 395 nm. The infrared spectra of the two isomers "A" and "B" are quite different, the ν_{NH} and $\nu_{C=O}$, streching frequencies differ for the two substances. The "A" isomer exhibits the strong and characteristic maxima of the ν_{NH} group at 3200 cm^{-1} and $\nu_{C=O}$ at 1730 cm^{-1}. The "B" isomer has no characteristic band for the NH group and the C = O group frequency is shifted to 1650 cm^{-1}, thus the presence of a hydrogen bond seen in the N.M.R. spectra is likewise confirmed. The "A" isomer presents in the N.M.R. spectra the NH proton singlet at 8.80 ppm and, as to the "B" isomer, the shift of the peak at 13.20 ppm confirms the existence of the hydrogen bond.

These facts suggest the following two formulas for the isomers :



"A" "B"

All the phenylhydrazones synthesized by us show a strong bathochromic shift in basic medium, the 360 nm band is shifted to 460 nm, and the 290 nm shoulder appears in all derivatives. The recording of the U.V.-visible spectra in KOH (methanol-water 1 : 1) of different concentrations demonstrates that the shifts and intensity of the bands vary with the hydroxide

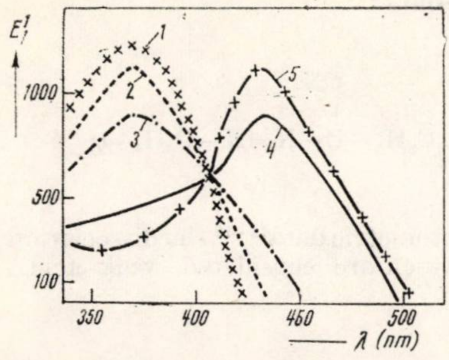


Fig. 2. – The U.V. spectra of benzoyl cyanide phenylhydrazone in various KOH concentrations, in aqueous methanolic solution 1: 1

(*1*, aqueous methanolic solution; *2*, 0.01 M KOH; *3*, 0.05 M KOH; *4*, 0.2 M KOH; *5*, 0.5 M KOH)

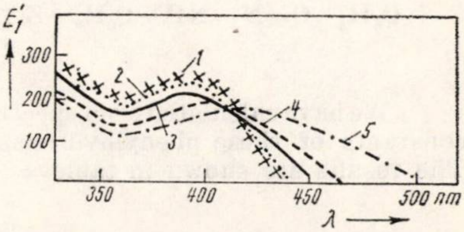

Fig. 3. – The U.V. spectra of benzoyl cyanide *ortho*-$COCH_3$ phenylhydrazone in various KOH solutions in aqueous methanolic solutions 1 : 1

(*1*, aqueous methanolic solution; *2*, 0.05 M KOH; *3*, 0.1 M KOH; *4*, 0.2 M KOH; *5*, 0.5 M KOH)

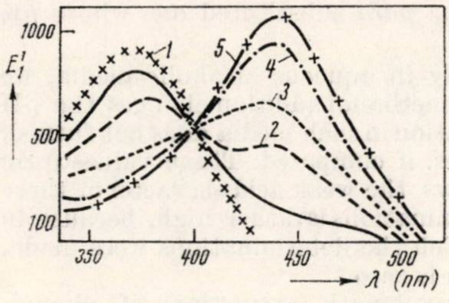

Fig. 4. – The U.V. spectra of benzoyl cyanide *meta*-$COCH_3$ phenylhydrazone in various KOH concentrations in aqueous methanolic solutions 1 : 1

(*1*, aqueous methanolic solution; 0.01 M KOH; *2*, 0.05 M KOH; *3*, 0.1 M KOH; *4*, 0.2 M KOH; *5*, 0.5 M KOH)

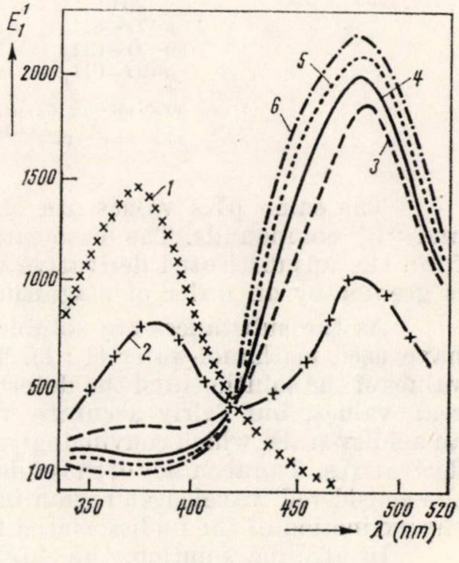

Fig. 5. – The U.V. spectra of benzoyl cyanide *para*-$COCH_3$ phenylhydrazone in various KOH concentrations in aqueous methanolic solutions, 1 : 1

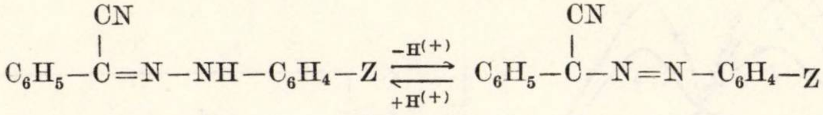
(*1*, aqueous methanolic solution; *2*, 0.01 M KOH; *3*, 0.05 M KOH; *4*, 0.1 M KOH; *5*, 0.2 M KOH; *6*, 0.5 M KOH).

concentration. Two isosbestic points are present in the 300–500 nm region, suggesting the following equilibrium :



$$C_6H_5-\overset{\overset{CN}{|}}{C}=N-NH-C_6H_4-Z \underset{+H^{(+)}}{\overset{-H^{(+)}}{\rightleftharpoons}} C_6H_5-\overset{\overset{CN}{|}}{C}-N=N-C_6H_4-Z$$

We have calculated from spectrophotometric data[16-19] the dissociation constants of these phenylhydrazones which are considered weak acids. The results are shown in table 4.

Table 4

pKs values of the benzoylcyanide phenylhydrazones

$$CN-\underset{\underset{C_6H_5}{|}}{C}=N-NH-C_6H_4-Z$$

Z	pKs	Δ_{pKs}
H	12.72	
o-CO–CH_3	12.33	−0.30
m-CO–CH_3	12.28	−0.44
p-CO–CH_3	11.71	−1.00

$pKs = pH - \log E_{ned}/(E_{dis} - E_{ned})$

$pKs = pKs^{Z} - pKs^{Z=H}$

The same pKs values are obtained for the *ortho* substituted "A" and "B" compounds. The dissociation constants increase as it is expected from the unsubstituted derivative to the *para* substituted one whose pK is greater by an order of magnitude.

As the substances are soluble only in aqueous alcoholic media, we have used methanol-water (1 : 1). The methanol addition changes the pH values of the solutions and the determination in such media does not furnish real values, but fairly accurate values, if compared. These values form an acidity scale, which convincingly shows the weak acid character of these derivatives. The accuracy of these determinations is rather high, because in the considered wavelength region in which the determinations were made, the extinction of the undissociated form is zero.

In alkaline solution, the high wavelength extinctions of phenylhydrazones decrease with the time, while those in the low region slowly increase. In order to clear up this effect, we have performed extinction measurements, at fixed intervals, of an aqueous alcoholic KOH 0.5 n solution.

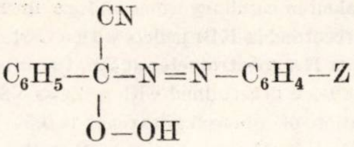
[17] C. REICHARD and W. GRAHM, *Chem. Ber.*, **103**, 1072 (1970).

[18] F. VLACIL, *Coll. Czech. Chem. Comm.*, **32**, 3183 (1967).

[19] J. SOCHA and M. VECERA, *Coll. Czech. Chem. Comm.*, **34**, 3740 (1969).

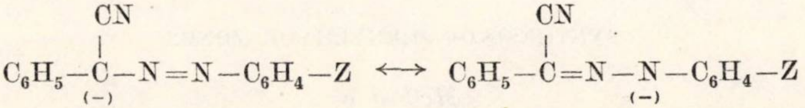
The presence of air oxygen has no influence upon the results, so that we do not consider that the derivative with the following formula :



$$C_6H_5-\overset{\overset{CN}{|}}{\underset{\underset{O-OH}{|}}{C}}-N=N-C_6H_4-Z$$

described by Yao, [6] could be present.

The decrease of the extinction in the 430–360 nm region suggests the following transition of the chromophore.



$$C_6H_5-\overset{\overset{CN}{|}}{\underset{(-)}{C}}-N=N-C_6H_4-Z \longleftrightarrow C_6H_5-\overset{\overset{CN}{|}}{C}=N-\underset{(-)}{N}-C_6H_4-Z$$

The rate constants of the assumed reaction are given in table 5.

Table 5

Rate constants of phenylhydrazones $CN-\overset{\overset{C_6H_5}{|}}{C}=N-NH-C_6H_4-Z$

Z	time in minutes	ln Ao/(Ao−x)	k_{det} min^{-1}	$(k \pm s^1)\cdot 10^3$ min^{-1}
H	500	1.30	2.50×10^{-3}	2.58±0.06
	1000	2.57	2.58×10^{-3}	
	1485	3.85	2.59×10^{-3}	
o-$CO-CH_3$	45	0.29	6.44×10^{-3}	6.45±0.02
	70	0.45	6.43×10^{-3}	
	118	0.76	6.48×10^{-3}	
m-$CO-CH$	620	0.44	7.00×10^{-4}	0.70±0.05
	1760	1.20	7.10×10^{-4}	
	3000	2.12	7.05×10^{-4}	
p-$CO-CH_3$	700	0.11	1.57×10^{-4}	0.15±0.01
	1800	0.28	1.55×10^{-4}	
	3000	0.50	1.56×10^{-4}	

$k = 1/t \ln Ao/(Ao-x)$

The extinction decrease in alkaline media is reversible. Acid treating of these solutions restores the initial spectra in acid solution.

In conclusion, the new phenylhydrazones we have prepared are weak acids presenting a chromophore group, sensitive only to alkali and not to the presence of oxygen. The dissociation and rate constants are varying with the substitution in the ring.

EXPERIMENTAL

Melting points were taken in capillary tubes and are uncorrected.

Infrared spectra were recorded in KBr pellets with a Carl Zeiss UR – 10 spectrophotometer and the N.M.R. spectra with a HA spectrometer at 20°, the solvent being $DCCl_3$.

The U.V. spectra have been determined with a Zeiss VSU-1 spectrophotometer, with 1 cm silica cells. The concentration of phenylhydrazones is $0.5-2 \cdot 10^{-5}$ M/l. The solutions were made up with methanol, methanol – H_2O 1 : 1, and methanolic aqueous solution (1 : 1) of KOH or HCl $0.5-5 \cdot 10^{-4}$ M/l. The dissociation constants were determined at 25° and the rate constants at 20°. The extinctions were determined at every 2 nm. The ionic strength was made 0.5 with KCl. The values of the dissociation constants were corrected to 0 time, the necessary correction being however very small.

SYNTHESIS OF PHENYLHYDRAZONES

Method a

0.01 moles of derivative possessing an active methyne group are suspended in 10 ml AcOH and 5 ml $B(OCH_3)_3$. To this solution at 0°, 0.01 moles of Z-phenyldyazonium fluoroborate are added under stirring. After 15 minutes 3 g AcOK, dissolved in 10 ml AcOH, are added. The reaction mixture is left until next day, then poured over 300 ml of water. The precipitate which is formed is filtered off. After drying the product is isolated from the solvents indicated in table 1.

Method b

0.01 moles Z-phenylamine hydrochloride are dissolved in 25 ml AcOH and 2 ml HCl. The mixture is diazotized at 0° with 0.01 butyl nitrite. The diazotized solution is poured dropwise over a mixture formed by 0.01 moles derivative with an active methine group, 30 ml AcOH and 3 g AcOK. After 24 hours the hydrazone is isolated by pouring over 300 ml water. The precipitate which is formed is filtered off. After drying, the product is isolated from the solvents indicated in table 1.

Method c

0.01 moles of derivative possessing an active methyne group are dissolved in 30 ml acetonitrile. To this solution, 0.01 moles of Z-phenyldiazonium fluoroborate are added at 0° and 3 ml triethylamine are dropped under stirring. The solution is maintained for 3 hours at 0°, then the hydrazone is isolated by pouring on 300 ml water. The precipitate formed is filtered off. The product is crystallized from the solvents indicated in table 1.

COMPTE RENDU

Gel permeation chromatography, Marcel Dekker Inc., New York, 1971, Ed. by K.H. ALTGELD and LEON SEGAL

The Symposium of the American Chemical Society held in February 1970 offered an opportunity to quite a number of important papers on theoretical basis, dealing with the experimental technique and the field of practical application of gel permeation chromatography, to be submitted.

Altgeld and Segal, two research workers with an important and long activity in the domain of polymers reference, have selected and systematized these papers in a volume offering to specialists a possibility to acquire a good knowledge of this method.

The book has 646 pages and classifies 43 papers into 4 chapters. The scientific status of the authors and the numerous fields approached ensure a high scientific level to the whole work.

The first chapter aims to inform the reader on the present problems connected to the appliance of this method to the chemistry of polymers, as well as on the separation possibilities and the limits of chromatography on permeable gel.

Chapter II deals with "Theories and methods of chromatography on permeable gel", discussing the theoretical interpretation of the collected data. The opportunity is used to present the methods of interpreting the data thus obtained, the calibration methods and the way of estimating the gel chromatograms.

Chapter III, "New developments of permeable gel chromatography" presents certain characteristic features of the method (the interpenetration effect, the dispersion effect), their theoretical interpretation, as well as the corrections to be applied to avoid them. Some new experimental proceedings (elution by recycling, rapid elution) ensuring an increase of the method efficiency, are meanwhile suggested.

Chapter IV, "The application of permeable gel chromatography in polymer chemistry and petrochemistry" presents the fields in which this method may be used. The chapter examines the numerous possibilities offered by this method to the synthetic and natural polymers, to identify the materials added in the polymerization processes, as well as the use of this method to characterize the mixtures made of small molecules.

The theroretical interpretation, the experimental data, the great number of fields approached, as well as the scientific status of the authors, confer to the whole work a high scientific level and gives it an essential character for specialists dealing with polymer- or petro-chemistry.

The graphical aspect and the way in which the material is presented permits an easy assimilation of all problems dealt with.

NOTE POUR LES AUTEURS

La *Revue Roumaine de Chimie* publie des articles en anglais, français, russe, allemand ou espagnol. Les auteurs sont priés d'envoyer des articles, notes communications et comptes rendus inédits.

Les manuscrits seront dactylographiés à deux intervalles. Les tableaux seront dactylographiés sur feuilles séparées, de même que la légende des figures. Les diagrammes seront tracés à l'encre de Chine sur papier calque. Les tableaux et les figures seront numérotés par des chiffres arabes, en nombre strictement nécessaire. Prière de ne pas inscrire les mêmes données dans les tableaux et les figures. Les formules chimiques seront incluses dans le texte ; en outre, elles seront transcrites sur des feuilles séparées. Les auteurs sont priés d'indiquer les caractères italiques (en soulignant les lettres au crayon), ainsi que tout autre caractère spécial. L'ordre des références bibliographiques sera celui de leur mention dans le texte ; le nom de l'auteur sera précédé de l'initiale du prénom ; les publications périodiques seront présentées suivant les prescriptions internationales. Les références seront ajoutées à la fin de l'article ; elles paraîtront comme des notes, au bas de la page. Le texte sera précédé d'un résumé, comprenant 15 lignes au maximum.

L'entière responsabilité du contenu des articles appartient aux auteurs. On publie des articles dus aux collaborateurs roumains ou étrangers. Les auteurs recevront 50 tirés à part.

DIFFUSION POTENTIALS IN MOLTEN SALTS

I. G. MURGULESCU and LUDMILA POPESCU
Centre of Physical Chemistry
Str. Galaţi 31, Bucharest, Romania

Received December 25, 1972

The diffusion potentials, ε_D in concentration cells of the type :

$$\mathrm{Ag}(s)\left|\begin{array}{l}\mathrm{AgX}(l),\ x^{\mathrm{I}}_{\mathrm{AgX}}\\ \mathrm{MeX}(l),\ x^{\mathrm{I}}_{\mathrm{MeX}}\end{array}\right\|\begin{array}{l}\mathrm{AgX}(l),\ x^{\mathrm{II}}_{\mathrm{AgX}}\\ \mathrm{MeX}(l),\ x^{\mathrm{II}}_{\mathrm{MeX}}\end{array}\left|\mathrm{Ag}(s)\right.$$

where X = Cl, Br and Me = Na, K, Rb, Cs have been determined as function of mole fraction and temperature. A quartz cell without diaphragm, the contact of the salts being achieved directly through a twisted capillary, has been used. A theoretical evaluation of the diffusion potential was attempted by considering the diffusion layer as a Henderson type one ; in some systems good agreement was obtained.

In molten salts the diffusion or junction potentials exist at the contact between two different mixtures of the salts.

The mixtures may have different concentrations of the active component as in the example :

$$\mathrm{Cu}(s)\left|\begin{array}{l}\mathrm{CuCl}(l),\ c_1\\ \mathrm{KCl}(l)\end{array}\right\|\begin{array}{l}\mathrm{CuCl}(l),\ c_2\\ \mathrm{KCl}(l)\end{array}\left|\mathrm{Cu}(s)\right. \qquad \text{(A)}$$

$$\mathrm{Ag}(s)\left|\begin{array}{l}\mathrm{AgCl}(l),\ x^{\mathrm{I}}_{\mathrm{AgCl}}\\ \mathrm{KCl}(l),\ x^{\mathrm{I}}_{\mathrm{KCl}}\end{array}\right\|\begin{array}{ll}\mathrm{AgCl}(l), & x^{\mathrm{II}}_{\mathrm{AgCl}}\\ \mathrm{KCl}(l), & x^{\mathrm{II}}_{\mathrm{KCl}}\end{array}\left|\mathrm{Ag}(s)\right. \qquad \text{(B)}$$

where c_1 and c_2 are the volume concentrations, x_{AgCl} and x_{KCl} the mole fractions. If in the cell (B), the molar fraction $x^{\mathrm{I}}_{\mathrm{AgCl}}$ is equal to one, the following asymmetric concentration cell results :

$$\mathrm{Ag}(s)\left|\ \mathrm{AgCl}(l)\ \right\|\begin{array}{l}\mathrm{AgCl}(l),\ x_{\mathrm{AgCl}}\\ \mathrm{KCl}(l),\ \ \ x_{\mathrm{KCl}}\end{array}\left|\mathrm{Ag}(s)\right. \qquad \text{(C)}$$

which is also met with in the study of molten salts by concentration cells with transport.

The mixtures of molten salts may differ with respect to the nature of their components as in the case of Daniell pyrogalvanic cells :

$$\mathrm{Zn}(l)\,|\,\mathrm{ZnCl_2}(l)\,||\,\mathrm{PbCl_2}(l)\,|\,\mathrm{Pb}(l) \qquad \text{(D)}$$

As in the electrolyte solutions, the diffusion potentials are also caused in molten salts by the difference in ionic mobilities of mixtures and are expressed by the same general equation :

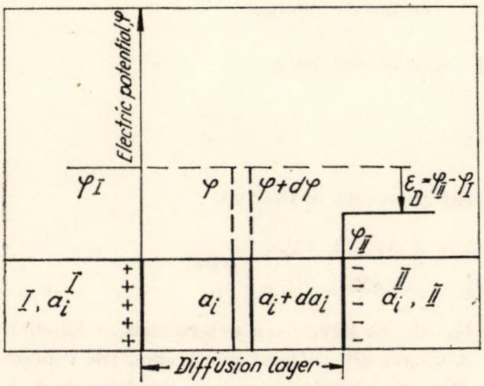

Fig. 1. — The diffusion layer and the corresponding diffusion potential.

$$\varepsilon_D = -\frac{RT}{F}\int_{\mathrm{I}}^{\mathrm{II}} \sum_i \frac{t_i}{z_i}\,\mathrm{dln}\,a_i \qquad (1)$$

where I and II represent the two compartments of the cell with transport which form the diffusion layer (Fig. 1). The other symbols have well-known meanings. The integration of equation (1) presents the same difficulties as in the case of electrolyte solutions.

That is why equation (1) may be successfully exploited only in the case of simple systems as those represented by concentration cells with transport of type (A), (B) and (C).

The concentration cells of type (A) are comparable to those formed in electrolyte solutions, the solvent being a molten salt, potassium chloride. At lower concentrations c_1 and c_2, the transport of current is effected by the ions of molten salts (KCl, NaCl, $\mathrm{NaNO_3}$) which play the role of a solvent ; the transport of the solute ions becomes zero and so does the diffusion potential.

This behaviour of (A) type cells has been confirmed by Gordon,[1] Sackur, [2] Blickslager, [3] Laity, [4] Blander and co-workers [5] and Bakès, [6]

[6] M. Bakès, *Ber. Bunsengesellschaft Phys. Chem.*, **70** 581 (1966).

The (C) type concentration cells formed the object of numerous researches. Since 1934, Grube and Rau [7] showed that cells as :

$$Pb(l)\,|\,PbCl_2(l)\,||\,PbCl_2(l),\ x_{PbCl_2} + KCl(l),\ x_{KCl}\,|\,Pb(l)$$

possess a diffusion potential of 30−40 mV.

After 1950, many works on diffusion potentials of (C) type concentration cells have been published, the results being remarkably contradictory. Thus, Murgulescu and Marchidan, [8] Terpiłowski and Josiak, [9] Langevin and co-workers [10] have obtained diffusion potentials of some milivolts, values which do not exceed the experimental errors. Concomitantly, in other mixtures, Bloom and Easteal[11], Behl and Egan [12] evidenced important values, up to 20 − 30 mV.

The present work deals only with the diffusion potentials of concentration cells with transport of (B) type.

The following cell of this type :

$$Ag(s)\left|\begin{array}{c} AgNO_3(l),\ x_1^I \\ NaNO_3(l),\ x_2^I \end{array}\right|\left|\begin{array}{c} AgNO_3(l),\ x_1^{II} \\ NaNO_3(l),\ x_2^{II} \end{array}\right| Ag(s)$$

was studied by Laity [4] who found a zero junction potential.

It is easily shown that in binary mixtures of molten salts with common anion, the diffusion potentials are zero if the transport number of the cations are proportional to the corresponding mole fractions.

Actually, admitting that the activity of the common anion which has the same mole fraction in both compartments of the cell, does not change with electrolyte composition (which may be not rigorously exact), the equation (1) for the former cell becomes

$$\varepsilon_D = -\frac{RT}{F}\int_{x_1}^{x_2}(t_{Ag^+} + \mathrm{dln}\, a_{Ag^+} + t_{K^+}\,\mathrm{dln}\, a_{K^+})$$

Taking into account Gibbs' equation,

$$x_{KCl}\,\mathrm{dln}\, a_{K^+} + x_{AgCl}\,\mathrm{dln}\, a_{Ag^+} = 0$$

the preceding equation becomes

$$\varepsilon_D = -\frac{RT}{F}\int_{x_1}^{x_2}\frac{x_{KCl}\, t_{Ag^+} - x_{AgCl}\, t_{K^+}}{x_{KCl}}\,\mathrm{dln}\, a_{Ag^+}$$

which gives immediately the condition that diffusion potential ε_D equals zero

$$x_{KCl}\, t_{Ag^+} - x_{AgCl}\, t_{K^+} = 0$$

that is

$$\frac{t_{Ag^+}}{t_{K^+}} = \frac{x_{AgCl}}{x_{KCl}}$$

The system studied by Laity could, by chance, accomplish this condition.

EXPERIMENTAL

The cell we used is represented in Fig. 2. Entirely made of quartz, the cell consisted of a test tube A (25 mm diameter, 250 mm length) containig the tube B which had at the end the twisted capillary C (1 mm internal diameter, 110 mm length). In the test tube, which was one of the compartments of the cell, one of the mixtures was introduced while in the capillary which was the second compartment, the other mixture was introduced. The junction between the electrolytes in the two compartments was so directly established through the corresponding diffusion layer.

Keeping the same level of the salts in both compartments, the twisted capillary (C) reduced the mechanical mixing to an acceptable extent and the diffusion layer formed within the capillary was of approximately 1 — 2 mm thick (which was observed by the difference in colour of the two mixtures).

Since the stability and reproducibility of emf of the cell depended on the way the diffusion layer is formed at the contact of the two mixtures, the following procedure has been used : the mixture for the tube (B) with capillary was prepared separately in another furnace at a temperature slightly higher than that of the main furnace, with the test tube A. Then, the B tube was filled with the mixture so prepared. The gas bubbles which could have formed in the capillary (and break the liquid column) were removed by forcing the mixture through the capillary and refilling it. The volume of the mixture in the test tube (approximately 10 cm^3) was previously calculated so as the open end of the capillary to be tangent to the level of the mixture in the test tube.

In addition, the working furnace was provided with an optical system formed of a prism with total reflexion and an ocular. This system allows the adjusting of capillary height depending on the mixture level so that the junction to be achieved through a thin layer.

A vertical furnace with a Kanthal resistance was used (Fig. 3). To lower the temperature gradient along the cell, ceramic discs were disposed around the cell in the inner tube of the furnace. Water running through copper tube coils disposed around the sheath of furnace was used for cooling.

Since the mixtures of silver halides and alkali halides corrode the silica walls, the cell has been washed after each run with diluted hydroflouric acid, so that the inner diameter of the capillary should not have been sensibly altered.

In order to check if the cell had an asymmetry potential, pure silver chloride has been introduced in both compartments together with two identical silver electrodes ; in the cell utilized in our experiments no asymmetry potential was evidenced.

The two silver electrodes were of silver wire of 99.9 % purity (3 mm diameter, 400 length). To avoid contact potentials, the silver electrodes were welded at two thinner silver wires which connected the cell to the meter. The silver electrodes were introduced in silica protection sheath, *D*.

Before every run the silver crystals formed during the previous run have been cleared out from the electrode and its thinned portions cut away.

The emf's have been measured with 0.1 mV precision; use has been made of a Solartron (type LM 1440.2) digital voltmeter of $2 \times 10^{10}\ \Omega$ internal resistance.

Fig. 2. — Experimental cell.

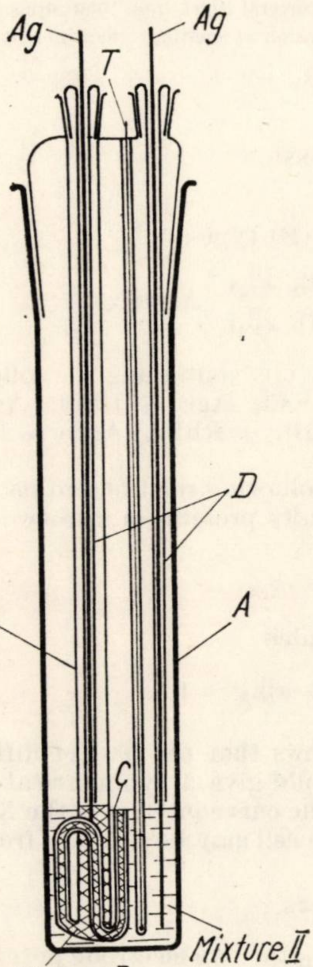

Fig. 3. — The furnace:

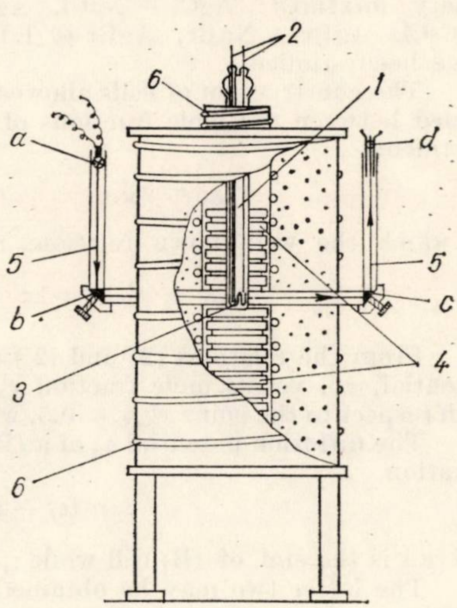
1 – experimental cell; *2* – silver electrodes; *3* – twisted capillary; *4* – ceramic discs; *5* – visualization device (*a*, light source; *b*, *c*, total reflexion prism with the possibility of adjusting the position; *d* – ocular); *6* – water cooling coils.



The temperature has been measured with a calibrated Pt/Pt 13% Rh thermocouple introduced directly into the mixture in the test tube; its emf was measured with a Feussner bridge.

Runs have been performed at each 10 degrees either increasing or decreasing temperatures and plots $\varepsilon_t = f(t^\circ)$ drawn for each mole fraction.

Junction between mixtures quickly established and the electrodes have been connected immediately to the meter.

Silver halides were prepared by precipitation of *p.a.*silver nitrate with *p.a.* corresponding hydro-acids; the precipitate was then dried, melted and purified by electrolysis (until silver traces were completely removed).

P.a. alkali halides have been purified by melting and bubbling with the corresponding gaseous hydro-acids; they have been preserved in desiccators.

Rubidium and cessium halides were recrystallized several times from their aqueous solutions in order to remove impurities appearing as suspension at melting; then melted in HCl or HBr gaseous stream.

RESULTS AND DISCUSSION

Concentration cells with transport of (B) type:

$$\mathrm{Ag}(s)\left|\begin{matrix}\mathrm{AgX}(l),\ x^{\mathrm{I}}_{\mathrm{AgX}}\\ \mathrm{MeX}(l),\ x^{\mathrm{I}}_{\mathrm{MeX}}\end{matrix}\right\|\begin{matrix}\mathrm{AgX}(l),\ x^{\mathrm{II}}_{\mathrm{AgX}}\\ \mathrm{MeX}(l),\ x^{\mathrm{II}}_{\mathrm{MeX}}\end{matrix}\left|\mathrm{Ag}(s)\right. \qquad \text{(B)}$$

where X = Cl, Br and Me = Na, K, Rb, Cs (i. e. containing the following binary mixtures: AgCl + NaCl, AgCl + KCl, AgCl + RbCl, AgCl + + CsCl, AgBr + NaBr, AgBr + KBr, AgBr + RbBr, AgBr + CsBr), have been studied.

The construction of cells allowed the following relations to be maintained between the mole fractions of the salts present in the two compartments

$$x^{\mathrm{I}}_{\mathrm{AgX}} = x^{\mathrm{II}}_{\mathrm{MeX}}; \qquad x^{\mathrm{I}}_{\mathrm{MeX}} = x^{\mathrm{II}}_{\mathrm{AgX}} \qquad (2)$$

to which the well-known relations are added

$$x^{\mathrm{I}}_{\mathrm{AgX}} + x^{\mathrm{I}}_{\mathrm{MeX}} = 1; \quad x^{\mathrm{II}}_{\mathrm{AgX}} + x^{\mathrm{II}}_{\mathrm{MeX}} = 1 \qquad (2')$$

From the relations (2) and (2′) it follows that the plot of diffusion potential, ε_D, versus mole fraction $x^{\mathrm{I}}_{\mathrm{AgX}}$ should give a symmetrical curve with respect to the point $x^{\mathrm{I}}_{\mathrm{AgX}} = 0.5$, where the curve intercepts the X axis.

The diffusion potential ε_D of a (B) type cell may be deduced from the equation

$$\varepsilon = (\varepsilon_{\mathrm{I}} - \varepsilon_{\mathrm{II}}) + \varepsilon_D \qquad (3)$$

where ε is the emf of (B) cell while ε_{I} and $\varepsilon_{\mathrm{II}}$ the two electrode potentials.

The latter two may be obtained from the corresponding formation cells:

$$\mathrm{Ag}(s)\left|\begin{matrix}\mathrm{AgX}(l),\ x^{\mathrm{I}}_{\mathrm{AgX}}\\ \mathrm{MeX}(l),\ x^{\mathrm{I}}_{\mathrm{MeX}}\end{matrix}\right|\mathrm{C(graphite)},\ \mathrm{X}_2\ (g,\ 1\ \mathrm{at})$$

$$\mathrm{Ag}(s)\left|\begin{matrix}\mathrm{AgX}(l),\ x^{\mathrm{II}}_{\mathrm{AgX}}\\ \mathrm{MeX}(l)\ \ x^{\mathrm{II}}_{\mathrm{MeX}}\end{matrix}\right|\mathrm{C(graphite)},\ \mathrm{X}_2\ (g,\ 1\ \mathrm{at})$$

It is easily seen that the difference between the emf's of the two formation cells equals $\varepsilon_{\mathrm{I}} - \varepsilon_{\mathrm{II}}$ from equation (3).

If the emf of (B) type cells are measured and the emf's of the suitable formation cells known we possess enough data to use equation (3) and calculate ε_D :

$$\varepsilon_D = \varepsilon - (\varepsilon_I - \varepsilon_{II}) \tag{4}$$

The emf's of formation cells have been available in literature; thus for AgCl + NaCl mixture, the emf was taken from Sternberg and Gheorghiu, [13] for AgBr + NaBr, AgBr + KBr and AgBr + RbBr from Salstrom, [14] for AgCl + KCl from Murgulescu and Sternberg [15] and for AgCl + RbCl and AgCl + CsCl from Pelton and Flengas. [16] Data for AgBr + + CsBr have been available in our own work. [17]

Activity coefficients deduced from the regular solutions equation:

$$RT \ln \gamma = \mathrm{B}\, x^2_{\mathrm{MeX}}$$

have been used in Nernst's equation to calculate emf's at mole fractions for which no data had been available, the binary mixtures under consideration having a regular behaviour.

In Tables 1 – 8 are listed the experimental results obtained in the cell we studied. In the last but one column, the values of diffusion potentials as deduced by equation (4) are listed.

Examination of tables shows that in (B) type concentration cells with transport, important diffusion potentials appear and their value may reach ± 20 mV. As expected, the larger are the composition differences between the compartments of the cells the higher the diffusion potentials.

The diffusion potentials also show a slight increase with temperature.

The dependence of diffusion potentials on silver halide concentration $x^{\mathrm{I}}_{\mathrm{AgX}}$ is drawn on Fig. 4 which refers to AgCl (l)+ KCl(l) cell (Table 2), for $T = 700°$.

A different behaviour is shown by the cells containing sodium salts. In these systems the change of diffusion potentials is more complicated, as comes out from Fig. 5 which represents data for AgCl(l) + NaCl(l) cell (Table 1), for $T = 700°$.

It is finally worth mentioning the relatively low values of diffusion potentials in cells with rubidium and cessium halides, especially at lower temperatures. This could be due to the inaccuracy of data for corresponding formation cells. Resuming the study of these cells is very indicated.

To compare the diffusion potentials in the above tables (last but one column) with the theoretical values given by equation (1), this equation should be integrated.

An exact integration is not possible since the individual activities a_i of the ions are not available. Approximate results may be obtained, as for electrolyte solutions, by making use of non-thermodynamic simplifying assumptions.

That is what we try in the following. Firstly, not to uselessly make intricate calculations we limit the treatment to common anion binary mixtures of the type $AC_1 + AC_2$, C_1^+ and C_2^+ representing the two cations Ag^+ and Me^+ with Me = Na, K, Rb, Cs and A^-, the common anion $X^-(X = Cl, Br)$.

Since the mole fraction of the anion is the same in both compartments of the studied cell, we assume that the activity remains approximately constant.

Table 3

$$\text{The cell : Ag}(s)\left|\begin{array}{l}\text{AgCl }(l),\ x^{\text{I}}_{\text{AgCl}}\\ \text{RbCl }(l),\ x^{\text{I}}_{\text{RbCl}}\end{array}\right\|\begin{array}{l}\text{AgCl}(l), x^{\text{II}}_{\text{AgCl}}\\ \text{RbCl}(l),\ x^{\text{II}}_{\text{RbCl}}\end{array}\left|\ \text{Ag}(s)\right.$$

0.6	+ 62.0	+ 60.0	+ 2.0	+ 9.5
0.7	+126.0	+120.0	+ 6.0	+19.1

Equation (1) takes then the form

$$\varepsilon_D = -\frac{RT}{F}\int_{\text{I}}^{\text{II}} (t_{\text{C}_1}\,\text{dln}\,a_{\text{C}_1} + t_{\text{C}_2}\,\text{dln}\,a_{\text{C}_2}) \qquad (5)$$

t_{C_1}, t_{C_2} and a_{C_1}, a_{C_2} being the transport numbers, respectively the activities of the cations C_1^+ and C_2^+.

The second hypothesis which we introduce regards the structure of diffusion layer. We assume that the diffusion layer has a structure analogous to that proposed by Henderson[18] for aqueous electrolytic solutions. In molten salts, this structure may be described by the following relations

$$a_{\text{C}_1} = a^{\text{I}}_{\text{C}_1} + (a^{\text{II}}_{\text{C}_1} - a^{\text{I}}_{\text{C}_1})x\,; \qquad a_{\text{C}_2} = a^{\text{I}}_{\text{C}_2} + (a^{\text{II}}_{\text{C}_2} - a^{\text{I}}_{\text{C}_2})x \qquad (6)$$

$$x_{\text{AC}_1} = x^{\text{I}}_{\text{AC}_1} + (x^{\text{II}}_{\text{AC}_1} - x^{\text{I}}_{\text{AC}_1})x\,; \qquad x_{\text{AC}_2} = x^{\text{I}}_{\text{AC}_2} + (x^{\text{II}}_{\text{AC}_2} - x^{\text{I}}_{\text{AC}_2})x \qquad (7)$$

The I and II denote as before the compartments of the cell to which the activities and mole fractions refer, and $0 < x < 1$. The transport numbers t_{C_1} and t_{C_2} become

$$t_{\text{C}_1} = \frac{x_{\text{C}_1}u_{\text{C}_1}}{x_{\text{C}_1}u_{\text{C}_1} + x_{\text{C}_2}u_{\text{C}_2} + x_{\text{A}}u_{\text{A}}}; \qquad t_{\text{C}_2} = \frac{x_{\text{C}_2}u_{\text{C}_2}}{x_{\text{C}_1}u_{\text{C}_1} + x_{\text{C}_2}u_{\text{C}_2} + x_{\text{A}}u_{\text{A}}}$$

u_{C_1}, u_{C_2} and u_{A} being the mobilities, while x_{C_1}, x_{C_2} and x_{A} the concentrations (molar fractions) of the ions indicated by subscript.

As $x_{\text{A}} = x_{\text{C}_1} + x_{\text{C}_2}$ the transport numbers become

$$t_{\text{C}_1} = \frac{x_{\text{C}_1}u_{\text{C}_1}}{x_{\text{C}_1}(u_{\text{C}_1} + u_{\text{A}}) + x_{\text{C}_2}(u_{\text{C}_2} + u_{\text{A}})}; \qquad t_{\text{C}_2} = \frac{x_{\text{C}_2}u_{\text{C}_2}}{x_{\text{C}_1}(u_{\text{C}_1} + u_{\text{A}}) + x_{\text{C}_2}(u_{\text{C}_2} + u_{\text{A}})}$$

However, $u_{\text{C}_1} + u_{\text{A}} = \lambda_{\text{AC}_1}$, $u_{\text{C}_2} + u_{\text{A}} = \lambda_{\text{AC}_2}$, λ_{AC_1} and λ_{AC_2} being the equivalent conductivities of the two salts AC_1 and AC_2. It is easy to notice that

Table 5

$$\text{The cell : Ag}(s) \left| \begin{matrix} \text{AgBr}(l),\ x^{\mathrm{I}}_{\mathrm{AgBr}} \\ \text{NaBr}(l),\ x^{\mathrm{I}}_{\mathrm{NaBr}} \end{matrix} \right\| \begin{matrix} \text{AgBr}(l),\ x^{\mathrm{II}}_{\mathrm{AgBr}} \\ \text{NaBr}(l),\ x^{\mathrm{II}}_{\mathrm{NaBr}} \end{matrix} \right| \text{Ag}(s)$$

0.7	+75.2	+60.2	+15.0	−2.5

$x_{\mathrm{C}_1} = \dfrac{x_{\mathrm{AC}_1}}{2}$ and $x_{\mathrm{C}_2} = \dfrac{x_{\mathrm{AC}_2}}{2}$ in which case the transport numbers take the form

$$t_{\mathrm{C}_1} = \frac{x_{\mathrm{AC}_1} u_{\mathrm{C}_1}}{x_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2}}; \qquad t_{\mathrm{C}_2} = \frac{x_{\mathrm{AC}_2} u_{\mathrm{C}_2}}{x_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2}}$$

Taking into account (2) and (7) one finally obtains

$$\left.\begin{aligned} t_{\mathrm{C}_1} &= \frac{[x^{\mathrm{I}}_{\mathrm{AC}_1} + (x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x]u_{\mathrm{C}_1}}{x^{\mathrm{I}}_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x^{\mathrm{I}}_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2} + (\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2})(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x} \\ t_{\mathrm{C}_2} &= \frac{[x^{\mathrm{I}}_{\mathrm{AC}_2} + (x^{\mathrm{II}}_{\mathrm{AC}_2} - x^{\mathrm{I}}_{\mathrm{AC}_2})x]u_{\mathrm{C}_2}}{x^{\mathrm{I}}_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x^{\mathrm{I}}_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2} + (\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2})(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x} \end{aligned}\right\} \quad (8)$$

The equations (5), (6) and (8) give

$$\varepsilon_D = -\frac{RT}{F}\int_0^1 \frac{[x^{\mathrm{I}}_{\mathrm{AC}_1} + (x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x]u_{\mathrm{C}_1}}{x^{\mathrm{I}}_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x^{\mathrm{I}}_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2} + (\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2})(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x} \cdot \frac{a^{\mathrm{II}}_{\mathrm{C}_1} - a^{\mathrm{I}}_{\mathrm{C}_1}}{a^{\mathrm{I}}_{\mathrm{C}_1} + (a^{\mathrm{II}}_{\mathrm{C}_1} - a^{\mathrm{I}}_{\mathrm{C}_1})x}\,\mathrm{d}x -$$

$$-\frac{RT}{F}\int_0^1 \frac{[x^{\mathrm{I}}_{\mathrm{AC}_2} + (x^{\mathrm{II}}_{\mathrm{AC}_2} - x^{\mathrm{I}}_{\mathrm{AC}_2})x]u_{\mathrm{C}_2}}{x^{\mathrm{I}}_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x^{\mathrm{I}}_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2} + (\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2})(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x} \cdot \frac{a^{\mathrm{II}}_{\mathrm{C}_2} - a^{\mathrm{I}}_{\mathrm{C}_2}}{a^{\mathrm{I}}_{\mathrm{C}_2} + (a^{\mathrm{II}}_{\mathrm{C}_2} - a^{\mathrm{I}}_{\mathrm{C}_2})x}\,\mathrm{d}x$$

If the activity coefficients $f^{\mathrm{I}}_{\mathrm{C}_1}$, $f^{\mathrm{II}}_{\mathrm{C}_1}$ and $f^{\mathrm{I}}_{\mathrm{C}_2}$ and $f^{\mathrm{II}}_{\mathrm{C}_2}$ are introduced the equation becomes

$$\varepsilon_D = -\frac{RT}{F}\int_0^1 \frac{[x^{\mathrm{I}}_{\mathrm{AC}_1} + (x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x]u_{\mathrm{C}_1}}{x^{\mathrm{I}}_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x^{\mathrm{I}}_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2} + (\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2})(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x} \times$$

$$\times \frac{f^{\mathrm{II}}_{\mathrm{C}_1}x^{\mathrm{II}}_{\mathrm{AC}_1} - f^{\mathrm{I}}_{\mathrm{C}_1}x^{\mathrm{I}}_{\mathrm{AC}_1}}{f^{\mathrm{I}}_{\mathrm{C}_1}x^{\mathrm{I}}_{\mathrm{AC}_1} + (f^{\mathrm{II}}_{\mathrm{C}_1}x^{\mathrm{II}}_{\mathrm{AC}_1} - f^{\mathrm{I}}_{\mathrm{C}_1}x^{\mathrm{I}}_{\mathrm{AC}_1})x}\,\mathrm{d}x -$$

$$-\frac{RT}{F}\int_0^1 \frac{[x^{\mathrm{I}}_{\mathrm{AC}_2} + (x^{\mathrm{II}}_{\mathrm{AC}_2} - x^{\mathrm{I}}_{\mathrm{AC}_2})x]u_{\mathrm{C}_2}}{x^{\mathrm{I}}_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x^{\mathrm{I}}_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2} + (\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2})(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x} \times$$

$$\times \frac{f^{\mathrm{II}}_{\mathrm{C}_2}x^{\mathrm{II}}_{\mathrm{AC}_2} - f^{\mathrm{I}}_{\mathrm{C}_2}x^{\mathrm{I}}_{\mathrm{AC}_2}}{f^{\mathrm{I}}_{\mathrm{C}_2}x^{\mathrm{I}}_{\mathrm{AC}_2} + (f^{\mathrm{II}}_{\mathrm{C}_2}x^{\mathrm{II}}_{\mathrm{AC}_2} - f^{\mathrm{I}}_{\mathrm{C}_2}x^{\mathrm{I}}_{\mathrm{AC}_2})x}\,\mathrm{d}x$$

Since the expressions of the individual activity coefficients (versus mole fractions x_{AC_1} and x_{AC_2}) are not accessible, the exact value of the integrals cannot be determined. To get approximate results and simplify the calculations we set

$$f^{\mathrm{I}}_{\mathrm{C}_1} \sim f^{\mathrm{II}}_{\mathrm{C}_1} \text{ and } f^{\mathrm{I}}_{\mathrm{C}_2} \sim f^{\mathrm{II}}_{\mathrm{C}_2} \tag{8'}$$

This is rough approximation which holds only for $x^{\mathrm{I}}_{\mathrm{AC}_1} \sim x^{\mathrm{II}}_{\mathrm{AC}_1}$ and $x^{\mathrm{I}}_{\mathrm{AC}_2} \sim x^{\mathrm{II}}_{\mathrm{AC}_2}$. For very different compositions in the two compartments of the cell a satisfactory agreement between the diffusion potentials so calculated and those deduced from formation cells is not to be expected.

On the basis of the above simplifying assumption, the diffusion potential becomes

$$\varepsilon_D = -\frac{RT}{F}[(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})u_{\mathrm{C}_1} + (x^{\mathrm{II}}_{\mathrm{AC}_2} - x^{\mathrm{I}}_{\mathrm{AC}_2})u_{\mathrm{C}_2}] \times$$

$$\times \int_0^1 \frac{\mathrm{d}x}{x^{\mathrm{I}}_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x^{\mathrm{I}}_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2} + (\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2})(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x}$$

Equation (2) and the condition $u_{\mathrm{C}_1} - u_{\mathrm{C}_2} = \lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2}$ lead to the following expression for diffusion potential

$$\varepsilon_D = -\frac{RT}{F}(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})(\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2}) \times$$

$$\times \int_0^1 \frac{\mathrm{d}x}{x^{\mathrm{I}}_{\mathrm{AC}_1}\lambda_{\mathrm{AC}_1} + x^{\mathrm{I}}_{\mathrm{AC}_2}\lambda_{\mathrm{AC}_2} + (\lambda_{\mathrm{AC}_1} - \lambda_{\mathrm{AC}_2})(x^{\mathrm{II}}_{\mathrm{AC}_1} - x^{\mathrm{I}}_{\mathrm{AC}_1})x} \tag{9}$$

Comparison of the last two columns in Tables 1 — 8 shows that equation (10) gives only a qualitative description of diffusion potentials in cells with transport except for cells in which sodium salts are present. When the compositions in the two compartments of the cell are not too different, the values of diffusion potentials, calculated according to equation (10), come very close to the experimental ones as expected. Similarly, with the increase of temperature, the differences between the theoretical and experimental values are smaller. The phenomenon is evident in AgCl + + KCl system; at 800° the difference is within experimental errors. It looks like as the temperature increases, the structure of the diffusion layer in cells, in given experimental conditions, is close to the structure given by Henderson.

We finally mention that equation (10) could be reached by introducing in equation (1) the activity coefficients and replacing the logarithm of products by sums of logarithms.

For mixtures of $AC_1 + AC_2$ we get:

$$\varepsilon_D = -\frac{RT}{F}\int_{\text{I}}^{\text{II}} (t_{C_1}\,\text{dln}\ C_1 + t_{C_2}\,\text{dln}\ C_2) - \frac{RT}{F}\int_{\text{I}}^{\text{II}} (t_{C_1}\,\text{dln}\ f_{C_1} + t_{C_2}\,\text{dln}\ f_{C_2})$$

Neglecting the second term and processing the first one as above we find again equation (10). The present approximation of activity coefficients proves to be equivalent to that introduced above by conditions (8′).

KINETICS AND MECHANISM OF THE THERMAL DECOMPOSITION OF AZIBENZIL. II[1]

STUDIES IN THE ABSENCE OF A SOLVENT

M. CONTINEANU *, TATIANA ONCESCU * and R. N. SCHINDLER **

* Physical Chemistry Laboratory, University of Bucharest,
Bd. Republicii 13, Romania
** Institut für Physikalische Chemie, Kernforschungsanlage
Jülich GmBH, Jülich, BRD

Received November 17, 1972

The kinetics and the mechanism of the thermal decomposition of azibenzil was studied below and above the melting point. The data obtained, following the rate of N_2 evolution during the reaction, indicate that the decomposition follows a first order kinetics in the absence of a solvent.

The spectrophotometric analysis of the products, at different reaction times, reveal that in addition to diphenylketene at least one other product is formed in the reaction.

INTRODUCTION

This paper describes the kinetics of the thermal decomposition of solid and molten azibenzil, respectively. No previous investigation on the decomposition of this compound, in the absence of a solvent, has been reported in the literature.

Our own preliminary experiments, carried out previously, indicated that the decomposition rate of molten azibenzil is comparatively high and from here arises a series of experimental difficulties.

EXPERIMENTAL

The rate of decomposition of molten azibenzil was directly followed in vacuum, recording the pressure of nitrogen evolved in the course of the reaction. The kinetics was studied at seven different temperatures in the range 80 – 102°. The experimental set-up is similar to that one described in a previous paper.[2]

---

[1] Part I, M. Contineanu, T. Oncescu and R. N. Schindler, *Rev. Roumaine Chim.*, in print (1973).

[2] M. Contineanu, T. Oncescu and R. N. Schindler, *Z. phys. Chem.* (Frankfurt), in print (1972).

The precision pressuremeter (Baratron-MKS) was part of the experimental arrangement. Using the same notation, the following volumes were determined : cell $V_c = 111.75$ cm^3 ; Inlet system $V_x = 232.11$ cm^3. It was established that the recorder deflection d (mm) was a linear function of N_2 pressure p (torr). A calibration constant of

$$p/d = \beta = 2.42 \times 10^{-2} \text{ Torr/mm}$$

was obtained for our set-up.

Applying first order treatment, straight lines were obtained when the time, at which a marked increase in N_2-production occurred was taken as start for the reaction.

The decomposition of solid azibenzil, i.e. below the melting point, was carried out at 60°, 65° and 75°, respectively. The reaction was again followed by measuring the N_2 pressure evolved with the Baratron Pressure Meter in a similar set-up as above. In this arrangement the following values for the volumes were measured :

Cell : $V_c = 102.3$ cm^3, Inlet System : $V_x = 198.55$ cm^3

In parallel experiments, spectrophotometric analyses were carried out with a Pye Unicam SP 1800 spectrophotometer. Data were obtained for the decomposition of solid azibenzil only.

After known reaction times t, the samples were suddenly cooled. Measurements were carried out in benzene solution at $\lambda = 320$ nm and $\lambda = 409$ nm, at which wavelengths the azibenzil and the diphenylketene, respectively, possess an absorption maximum.

RESULTS AND DISCUSSION

The pressure changes obtained as function of reaction time in the decomposition of azibenzil at temperatures above the melting point are given in fig. 1. Since the working temperature of the thermostat is not instantaneously reached by the sample, sigmoid shaped curves for the N_2 yield are registered in all experiments.

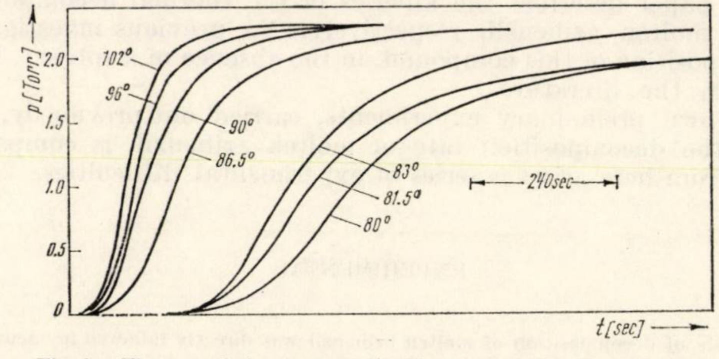

Fig. 1.—The recorded curves of the N_2 pressure function of time

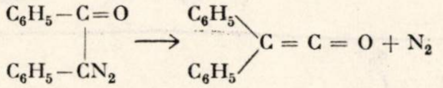
We have, therefore, considered as the starting point of the reaction the moment at which a marked increase of the N_2 pressure could be noticed. The results given in figure 1 clearly demonstrate that the same plateau is reached for all temperatures. This suggests that the reaction is carried out in all experiments to total decomposition according to the equation (A) as in solution.



(A)

Separate experiments were undertaken to establish this assumption by quantitative determination of the total amount of N_2 formed. The same technique was applied as in a previous paper.[2] The average of the results obtained lead to 4.32×10^{-5} moles N_2, which agrees well with the theoretical value of 4.5×10^{-5} moles.

With n_{N2} and n_A describing the number of moles N_2 and azibenzil, respectively, at time t, the formation rate of N_2 is given by

$$\frac{dn_{N2}}{dt} = k_1 n_A = k_1 n_A^0 \cdot e^{-k_1 t} \tag{1}$$

where n_A^0 is the initial number of azibenzil moles. From reaction (A) we obtain $n_A^0 = n_{N2}^0$ if n_{N2}^0 is the number of N_2 moles at total decomposition of azibenzil. Integration of equation (1) yields (2)

$$k_1 = \frac{2.303}{t} \lg \frac{n_{N2}^0}{n_{N2}^0 - n_{N2}} \tag{2}$$

Since the rate of N_2—production is directly proportional to the measured deflection of the pressure meter, equation (2) can be written in the form (3)

$$k_1 = \frac{2.303}{t} \lg \frac{d_\infty}{d_\infty - d_t} \tag{3}$$

In this equation d_∞ denotes the deflection at total decomposition, i.e. at time ∞ and d_t the deflection at time t.

The registered curves given in figure 1 have been evaluated according to (3). Straight lines were obtained for all temperatures (fig. 2) showing that the evolution of N_2 follows a first order kinetics after the sample has reached thermal equilibrium.

As mentioned, a clear deviation is observed for the initial part of the reaction. As examples are given in figure 2 the temperatures 83° and 86°.

From the slope of the straight lines denoted as tg α the rate constants for the individual temperatures were calculated as follows

$$\operatorname{tg} \alpha = 1/(t_1 - t_2) \times \left(\lg \frac{d_\infty}{d_\infty - dt_1} - \lg \frac{d_\infty}{d_\infty - dt_2} \right) \tag{4}$$

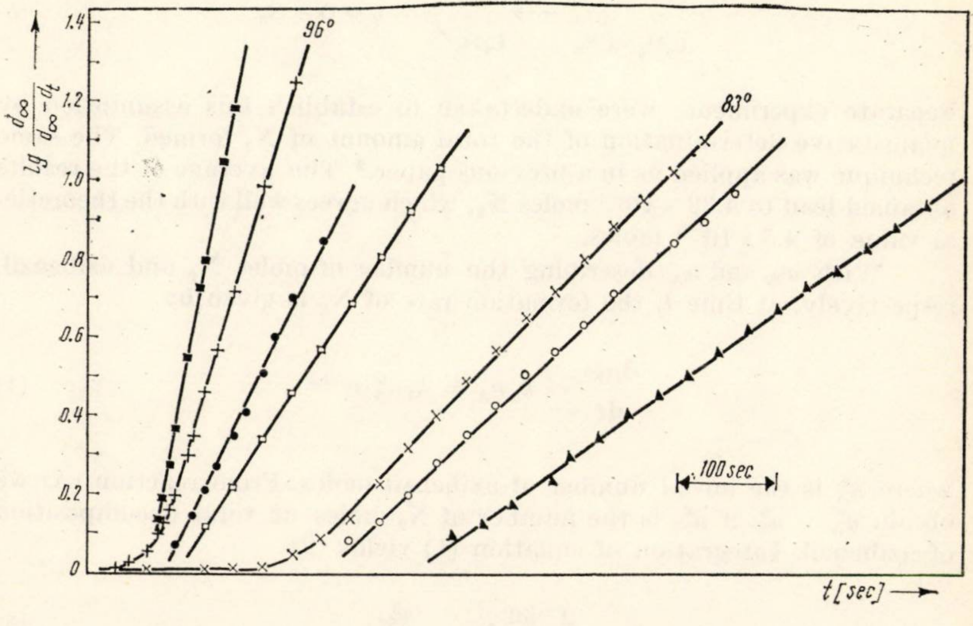


Fig. 2. — The plotting of $\lg \dfrac{d_\infty}{d_\infty - d_t}$ versus time (sec).

The rate constant k_1 is then obtained as

$$k_1 = 2.303 \operatorname{tg} \alpha \tag{5}$$

Table 1

Kinetic parameters of the azibenzil decomposition above its melting point

T	$\frac{1}{T} \times 10^3$ K^{-1}	$(\mathrm{tg}\alpha)_m \times 10^3$	$(k_1)_m \times 10^3$ sec^{-1}	$\lg A$
80	2.8329	1.85	4.24	13.65
81.5	2.8209	2.313	5.34	13.68
83	2.8089	2.62	6.02	13.85
86.5	2.7816	3.95	9.1	13.68
90	2.7549	5.53	12.74	13.69
96	2.7100	8.6	19.83	13.79

$(\lg A)_a = 13.74$

The data taken from figure 2 are summarized in table 1. The k-valnes given in the fourth column are average values from several recordings.

The preexponential factors listed in the last column show good constancy. The average value obtained is lg $A = 13.74$.

A plot of log k_1 versus $1/T$ for the decomposition of azibenzil above the melting point is given in figure 3.

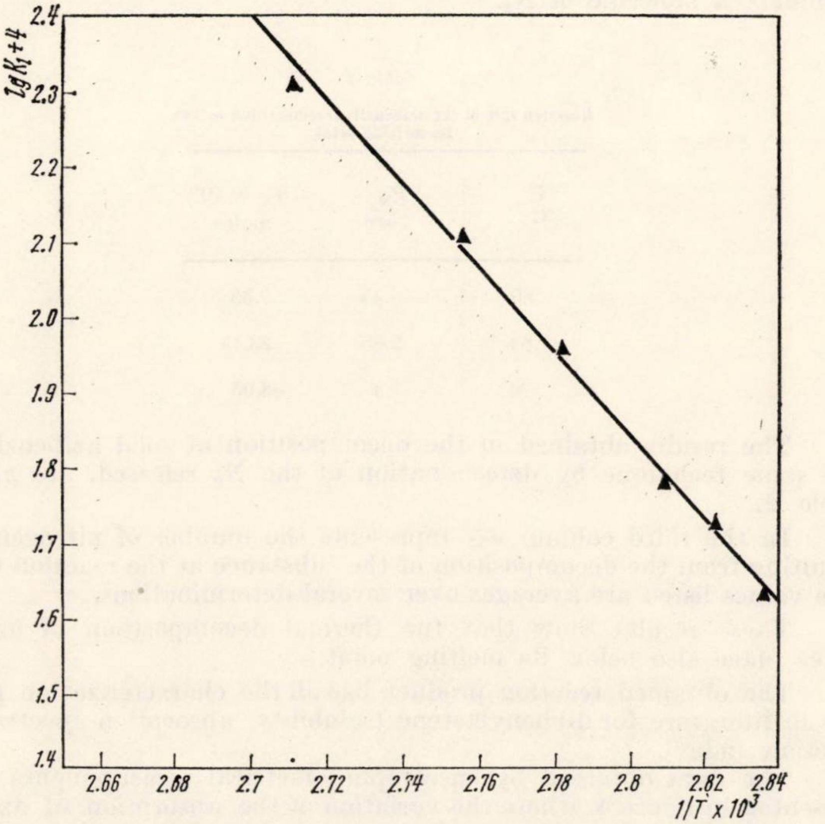

Fig. 3. – The plotting lg k_1 versus $1/T$.

An activation energy $E_A = 25.9$ kcal/mole was obtained from the slope of this line. This value is practically identical with the activation energy of azibenzil decomposition in benzene solution.[1] This result clearly indicates that benzene is an inert solvent, for the azibenzil decomposition, which does not modify the mechanism of the reaction. The activation energy refers thus to the monomolecular decomposition process.

It is of interest to speculate about the reason for the difference in the activation energy for azibenzil and diphenyldiazomethane decomposition for which compound $E_A = 22.3$ kcal/mole has been obtained.[3] The main difference between these two diazoic compounds appears to be the stabilizing effect of the carbonyl group in the azibenzil. Since the $>C=O$—electrons participate in the mesomeric system,[4] the extended charge delocalization in the parent azibenzil brings about a higher stability than in the diphenyldiazomethane. Thus, more energy is required to eliminate a molecule of N_2.

Table 2

Reaction rate of the azibenzil decomposition below its melting point

T °C	P_{N_2} Torr	$n_{N_2} \times 10^6$ moles
60	0.45	7.33
65	2.85	23.15
70	5.4	88.05

The results obtained in the decomposition of solid azibenzil, with the same technique by determination of the N_2 released, are given in table 2.

In the third column n_{N_2} represents the number of nitrogen moles resulting from the decomposition of the substance at the reaction times t. The values listed are averages over several determinations.

These results show that the thermal decomposition of azibenzil takes place also below its melting point.

The obtained reaction product has all the characterization pointed out in literature for diphenylketene (solubility, absorption spectrum, refraction index).

The data obtained by spectrophotometrical measurements are represented in figure 4, where the variation of the absorption of azibenzil, at $\lambda = 320$ nm (curve 1) and of the preponderant final product diphenylketene (curve 2) at $\lambda = 409$ nm ($k_A = 103$, $k_{DK} = 270$) are plotted versus reaction time for the temperature of 60°.

Three regions can be discerned on curve I. On the first (0—120′) the absorption is kept practically constant, which shows that the substance has not decomposed. In the second region (120 — 360′), the absorption suddenly decreases, while it is again kept constant in the third region.

We must mention the fact that during the heating of the substance a change of its aggregation state is observed. On the first part the substance is solid, on the second it gets softer and on the last part it is practically in liquid state as the pure diphenylketene is.

It therefore results that the sudden decrease of the absorption and thus the decomposition of azibenzil coincides with the formation of liquid diphenylketene in this system.

---

[4] W. JUGELT and D. SCHMIDT, *Tetrahedron*, **25**, 969 (1969).

Curve 2 in figure 4 shows that the sudden decrease of the absorption at $\lambda = 320$ nm is accompanied by a sudden increase of absorption at $\lambda = 409$ nm. This proves that while the substance decomposes the diphenylketene is formed on account of the azibenzil.

In the third region the system becomes liquid due to diphenylketene, the dominant reaction product, which is liquid at that temperature.

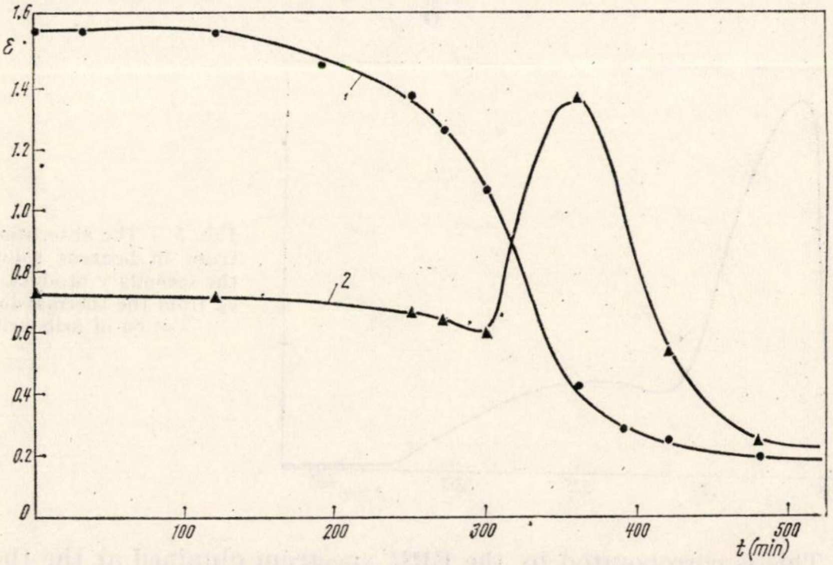

Fig. 4. – The variation of the absorption during the thermal decomposition
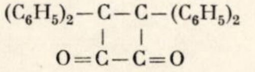
1 of azibenzil at $\lambda = 320$ nm
2 of diphenylketene at $\lambda = 409$ nm

In this region the absorption should have decreased to nil (if the final reaction product was only diphenylketene) as it does not absorb at $\lambda = 320$ nm, but we notice that the absorption keeps practically constant, around 0.2. This is due to the absorption of another final reaction product which appears at the same time.

Indeed, especially for low degree decomposition (room temperature), there appears, besides diphenylketene, a colourless substance. This separates from the ketene, being insoluble in hexane, and a melting point could be determined for it at 159°. The chemical analysis has lead to 82.5% C, 5.95% H, which has not allowed us to assign it an exact formula. The possibility of the presence of the corresponding ketazine is out because the nitrogen is not dosed by chemical analysis. This result is in agreement with the one obtained by Curtius. [5] The respective substance can be a dimer type one [6,7]



$$\begin{array}{c}(C_6H_5)_2-\underset{|}{C}-\underset{|}{C}-(C_6H_5)_2\\ O=C-C=O\end{array}$$

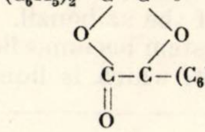
or an oxygen compound of type[8] :



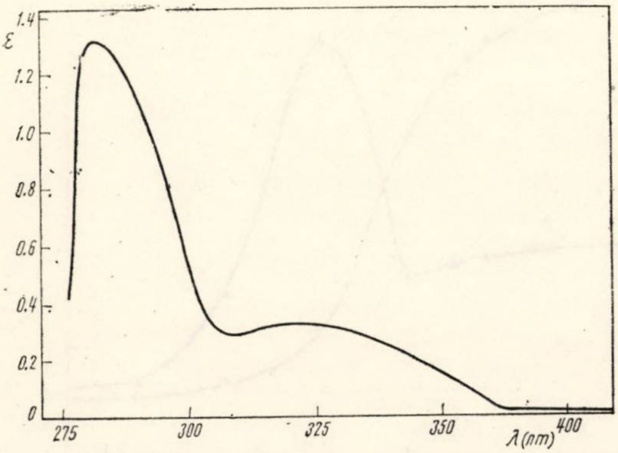


Fig. 5 – The absorption spectrum in benzene solution of the secondary product resulted from the thermal decomposition of azibenzil.

This is corroborated by the EPR spectrum obtained at the thermal decomposition of azibenzil, [9] when a signal is originated by a radical strongly influenced by the presence of O_2. This can be only the intermediate species leading towards such an oxygenated compound.

The absorption spectrum of this substance in benzene is given in figure 5, where it can be seen that it presents enough absorption at $\lambda = 320$ mm.

To conclude, we may state that from the kinetic data obtained

– only the formation of N_2 can reflect the kinetics of the unimolecular process of the azibenzil thermal decomposition;

– the diphenylketene formation, the main reaction product can not serve for this purpose, because as one can see from figure 4 (the descendent side of curve 2) it transforms chemically too :

– one can also establish that, besides diphenylketene, undoubtedly at least one more substance is formed and identified by its melting point, its absorption spectrum and its chemical analysis.

MASS SPECTRUM OF DIPHENYLDIAZOMETHANE

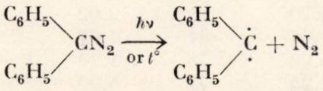
M. CONTINEANU, C. PODINĂ and V. CONSTANTIN

University of Bucharest, Department of
Physical Chemistry, Bd. Republicii 13, Romania

Received August 21, 1972

The mass spectrum of diphenyldiazomethane was recorded at 70 eV. The formation mechanism of the ions corresponding to the main peaks of the spectrum are proposed. The relative stability of ions *m/e*= 165 and *m/e* = 166 as function of electrons energy is discussed.

The photochemical and thermal decomposition of solid diphenyldiazomethane has been studied in former works.[1,2] In both cases a nitrogen molecule is eliminated through the absorption of thermal energy or of radiation and the diphenylcarbene appears as an intermediate species (reaction 1):



(1)

Aiming to establish the possible correlations with the thermal and photochemical decomposition we have studied the ionic species formed through electronic bombardment (much higher energies than those of the above mentioned agents) of diphenyldiazomethane. The mass spectrum of this compound was studied by Schumann and co-workers.[3] They have studied comparatively the influence of $\rangle C=Y$ ($Y= 0$, S and N_2) groups bounded in some aromatic compounds with more phenyl rings, upon the main fragmentation processes.

EXPERIMENTAL

The diphenyldiazomethane was obtained by oxidizing the corresponding hydrazone.[4] The mass spectra were recorded at room temperature by means of an M.I.1305 type mass spectrometer. The sample to be analysed was introduced and vaporized directly at the

ion source of the device. The working parameters were as follows : emission current 1.5 mA, ionization voltage 70 V, acceleration voltage 4kV, pressure at the ion source $5 \cdot 10^{-6}$ mm Hg.

RESULTS AND DISCUSSIONS

Table 1 gives the relative intensities corresponding to ions with higher peaks than 1% of the basic peak's height ($m/e = 165$).

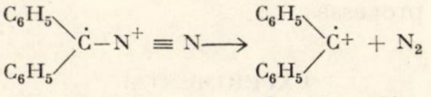
Table 1

Mass spectrum of diphenyldiazomethane at 70 eV

m/e	Ion abundance	*m/e*	Ion abundance	*m/e*	Ion abundance
194	0.81	113	3.07	76	2.55
182	1.56	105	4.38	75	3.28
168	1.98	99	1.09	74	4.07
167	10.95	98	1.56	65	1.67
166	62.50	89	4.17	64	1.41
165	100.00	88	2.19	63	8.71
164	13.90	87	4.69	62	4.37
163	11.00	86	3.13	53	2.31
162	1.77	83	4.38	52	1.61
152	1.25	82.5	9.36	51	8.15
140	1.25	82	6.57	50	4.68
139	9.70	81.5	3.02	39	7.20
138	1.04	81	1.67	38	1.67
115	5.63	78	1.20	28	2.08
114	1.25	77	5.00	27	2.24

The most intense ions of the spectrum are those having a 165 and 166 specific mass.

As could be expected, taking into account the strength of the C —N and N ≡ N bonds, the main primary fragmentation process of the molecular ion is the elimination of an N_2 molecule with the formation of the ion-radical $(C_6H_5)_2C^+$ according to reaction :



$$(C_6H_5)_2\dot{C}-N^+\equiv N \longrightarrow (C_6H_5)_2\dot{C}^+ + N_2 \qquad (2)$$

a, *m/e* = 194 **b**, *m/e* = 166

Under this aspect the phenomenon is like the thermal and photochemical decomposition.

Informations about the structure of the ion-radical $(C_6H_5)_2\dot{C}^+$ may be inferred from the E.S.R. studies on the diphenylcarbene [5–8]

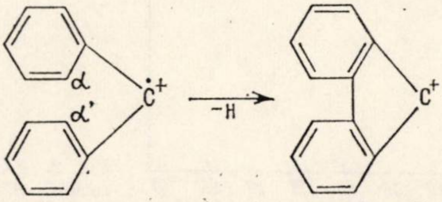
$(C_6H_5)_2\dot{C}$. This is a radical in triplet state in which the two phenyls are in the same plane and are placed at an approximately 140 — 150° degree one another. The odd electrons are each to be found in a *p* orbital. Taking into account the structure of the diphenylcarbene we may state that the ion-radical $(C_6H_5)_2\dot{C}^+$ is similar to it, the only difference being the inexistence of a *p* orbital.

The **b**, $m/e = 166$ ion being less stable because of the impar electron it contains, tends to stabilize through a re-setting process with the formation of a cycle of five.

The mechanism of this process is displayed according to reaction (3). One of the hydrogen atoms of α or α' positions is eliminated, while the other is transferred to the carbon atom carrying positive charges with the formation of the fluorenyl (**c**, $m/e = 165$) cation. [3]



b, m/e = 166 **c**, m/e = 165 (3)

The latter, unlike the diphenylcarbene ion, does not possess an uncoupled electron and shall, therefore, have a higher stability, which explains the fact that the corresponding peak is the most intensive of the spectrum (the basic peak).

It is interesting to point out that the intensities of the $m/e = 166$ and $m/e = 165$ ions vary differentily according to the energy of the ionizing electrons.

Figure 1 gives the dependence of the ratio R, between the intensity of the $m/e = 165$ ion and that of the $m/e = 166$ ion, versus the acceleration potential of the electrons.

One notices that for higher energies than 50 eV this ratio is > 1 and maintains a practically constant value (1.7). For energies lower than 50 eV the value of this ratio decreases perceptibly becoming 1 between 29 — 30 eV, and then rapidly decreasing parallelly to the energy. This means that concomitantly to the decrease of the ionizing electrons energy, the probability of the process represented by reaction (3) also decreases considerably. Reaction (3) is, therefore, conditioned by the electronic excitation energy possessed by the diphenylcarbenic ion-radical ($m/e = 166$). When this excitation energy is small, the $m/e = 166$ ion-radical does no longer undergo the re-setting process in the fluorenyl cation. This is in agreement with the results formerly obtained by thermic and photochemical decomposition, when the energy received by the molecule is much lower than the value of the appearance potential of the ion-radical $m/e = 166$ and, therefore, only the diphenylcarbene in triplet state is formed.

The group of double charged ions from $m/e=183$ up to $m/e=81$ with a relatively high intensity proves that parallelly to the formation of the fluorenyl cation (process (3)) there also takes place an elimination of the contained odd electron, leading to the appearance of doubly charged ions. This would be one more argument in favour of the radical structure of the diphenylcarbene ion.

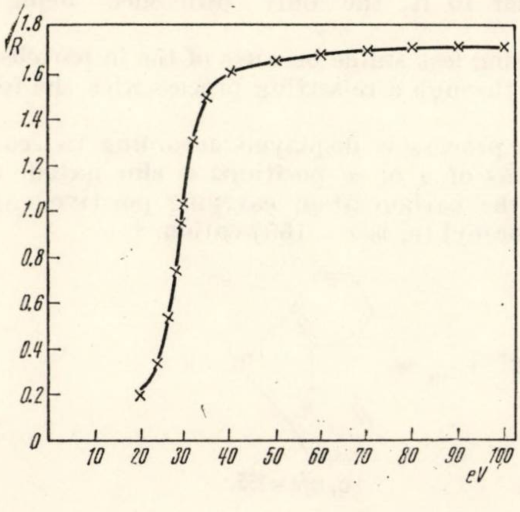


Fig. 1. — Variation of the ratio between the intensities of ions *c* and *b* versus the energy of the ionizing electrons.

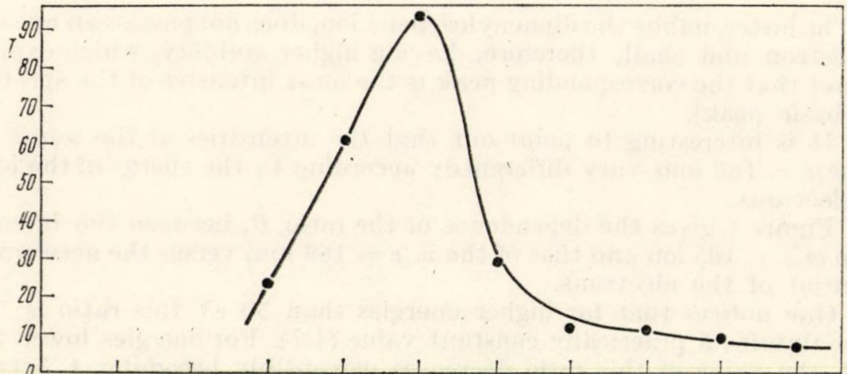
Fig. 2. — Curve of the ionization efficiency of the molecular ion.



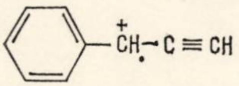
The molecular ion is to be found at $m/e = 194$ and is of small intensity (<1 %), which shows the instability of the diphenyldiazomethane molecules at electronic impact. This intensity depends on the energy of the ionizing electrons and presents a marked maximum around 50 eV (figure 2).

The peaks at $m/e = 167$ and m/e 168 are isotopic peaks of the ions with specific masses m/e 165 and m/e 166. The peaks at $m/e = 164$ and m/e 163 are evidently formed through successive hydrogen losses from m/e 165.

The ion $m/e = 139$ also results from the ion m/e 165 through the breaking of a benzenic cycle and the elimination of a neutral acetylene molecule. The process is confirmed by the existence in the spectrum of a metastable ion found at $m/e = 117.2$ (by calculation 117.1).

One also notices the existence of a group of doubly charged ions around the specific mass of 69.5, the intensity of which, compared to basic peak, is $< 1\%$ but they represent approximately 4% of the $m/e=$ 139 ion's intensity. It can be thus inferred that the $m/e = 139$ ion has also a radical structure.

The breaking up of the benzenic cycle of the $m/e = 166$ ion leads to the formation of the $m/e = 115$ and $m/e = 51$ ions. This process is justified by the existence of the metastable ion at $m/e = 79.8$ (by calculation 79.7), corresponding to the keeping of the charge on the $m/e= 115$ fragment. The structure of these ions may be represented by :



$m/e = 115$

$CH \equiv C - CH = CH^{+}$ $m/e = 51$

By comparing the intensities of the respective peaks, we may state that the repartition of the positive charge in this breaking up process takes place approximately with the same probability on both fragments.

The smaller intensity of the $m/e = 115$ ion, compared to the $m/e =$ 51 ion, is explained by the fact that it can further eliminate a neutral acetylene molecule forming the $m/e = 89$ ion. The latter can lose two and three hydrogen atoms passing into the $m/e=87$ and, respectively, $m/e=$ 86 ions.

Through the elimination of a neutral radical $C_4H_3^{\cdot}$ of the $m/e = 139$ ion, the $m/e = 88$ ion is formed. In this breaking up process, a metastable ion also appears at $m/e = 55.5$ (by calculation 55.7). By the breaking of the fluorenyl radical and elimination of $C_4H_4^{\cdot}$, the $m/e = 113$ ion is formed.

In the recorded mass spectrum there have also been rendered evident more abundent ions at $m/e < 78$, ions appearing in the spectra of aromatic hydrocarbons and evidently having their origin in the breaking up of the benzene ring.[9]

CONTRIBUTION À L'ÉTUDE DE LA SOURCE CHIMIQUE DE COURANT $Zn/MOH/O_2$. I

L'EFFICACITÉ ÉLECTROCHIMIQUE D'UNE PILE À CATHODE ACTIVÉE AVEC DE L'ARGENT

O. RADOVICI, MARIA MAVRODIN-TĂRĂBÎC, IOANA ONACA et I. SOLACOLU
Centre de Chimie Physique, Bucarest, 31, str. Galaţi

Reçu le 12 juillet 1972

On a réalisé une source chimique de courant du type zinc-oxygène à cathode, poreuse activée avec de l'argent. Les données thermodynamiques de la réaction, ainsi que les courbes V-i, ont permis le calcul du rendement thermodynamique, électrique et total réalisé dans la conversion de l'énergie chimique en énergie électrique.

La pile du type métal-air représente une source chimique de courant, dont le rôle est de transformer directement l'énergie chimique du combustible en énergie électrique ; ce type de pile peut être considéré comme une combinaison entre une source chimique primaire classique (anode métallique) et une pile à combustible (cathode alimentée dynamiquement avec de l'oxydant). Parmi les piles métal-air ce sont surtout les sources chimiques Zn/électrolyte alcalin /O_2 (air) [1,2] qui se remarquent par leur efficacité.

La réaction chimique se trouvant à la base de l'obtention du courant électrique est l'électrooxydation du zinc en milieu alcalin concentré, ayant pour résultat la formation de l'ion $Zn(OH)_4^{2-}$. [3,4]

Tout comme dans le cas des piles à combustible, la rendement de la conversion de l'énergie chimique en énergie électrique réalisé dans les piles du type métal-air est élevé et nettement supérieur aux rendements réalisés dans le cas des machines thermiques classiques, ce qui démontre que ce type de sources chimiques de courant représente un procédé avantageux pour l'obtention de l'énergie électrique. Le rendement de la conversion de l'énergie dépend tant du rendement thermodynamique de la

réaction chimique qui est à la base de l'obtention du courant électrique dans les conditions pratiques de fonctionnement, que du rendement électrique de la pile, dont la valeur varie selon la grandeur des pertes énergétiques irréversibles (polarisation de transfert de charge, de concentration et de résistance ohmique, pertes ohmiques dans les conducteurs).[5]

Etant donné que les applications pratiques des sources chimiques du type métal-air sont limitées aux domaines où elles ne sont pas concurrencées par le prix de revient relativement réduit de l'énergie électrique obtenue par les procédés classiques et que le rendement de la conversion de l'énergie constitue une caractéristique déterminante de la grandeur du prix de revient de l'énergie électrique, les études concernant l'amélioration du rendement énergétique de ces sources de courant présentent un intérêt considérable.

Dans ce travail nous nous sommes proposé de réaliser une étude détaillée du rendement thermodynamique et électrique d'une pile zinc-oxygène que nous avons construite dans notre laboratoire, et d'établir la valeur du rendement d'une telle source chimique de courant dans les conditions de l'obtention, en circuit ouvert, d'une puissance maximale.

PARTIE EXPÉRIMENTALE

1. LA RÉALISATION DE LA SOURCE CHIMIQUE DU TYPE MÉTAL-AIR

On a réalisé, dans notre laboratoire, une pile métal-air, du type :

(−) $Zn/KOH\ 5\ N/O_2(Ag)$ (+)

Pour la réalisation de cette pile on a utilisé :

— une anode de zinc (pureté 99,9 %),

— une cathode — électrode à gaz du type DSK (« Doppel Skelet Katalyst ») avec une porosité globale de 45 %, activée avec de l'argent, obtenue et caractérisée, ainsi que nous l'avons montré dans un travail antérieur,[6]

— un électrolyte KOH *p.a.* 5 N,

— un dépolariseur cathodique — oxygène, à des surpressions de 300 et de 400 mm Hg.

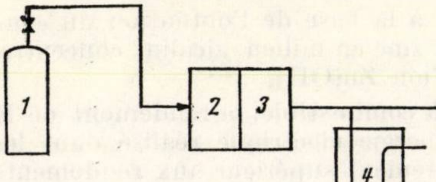

Fig. 1. — Schéma de l'installation pour l'alimentation avec de l'oxygène, à surpression constante, de la cathode de la pile zinc-oxygène.

1, bouteille à oxygène, *2*, réducteur, *3*, réducteur de réglage fin, *4*, manomètre à mercure, *5*, vers la cathode de la pile.

L'alimentation de la cathode avec de l'oxygène, à surpression constante, a été réalisée à l'aide de l'installation représentée dans la figure 1. La température de travail a été d'environ 25° et la cellule, ayant les dimensions 120 × 72 × 56 mm, a été confectionnée en polystyrène.

---

2. LES MESURES ÉLECTRIQUES

En vue de déterminer les courbes de décharge V-i de la pile zinc-oxygène réalisée dans notre laboratoire, à différentes surpressions de l'oxygène, la source chimique de courant a été déchargée, tout en variant la résistance, dans le montage représenté dans la figure 2, en utilisant un millivoltmètre électronique Radiometer 22 (précision ± 1 mV), un milliampèremètre de classe 0,5, une boîte à résistances (précision ± 0,1 Ω).

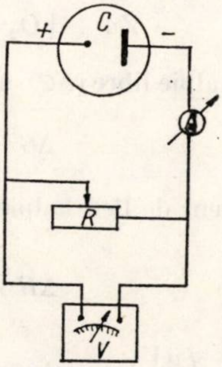

Fig. 2. — Schéma du montage utilisé pour la décharge de la pile zinc-oxygène.

C — la cellule, *A* — milliampèremètre, *V* — millivoltmètre électronique, *R* — résistance décadique.

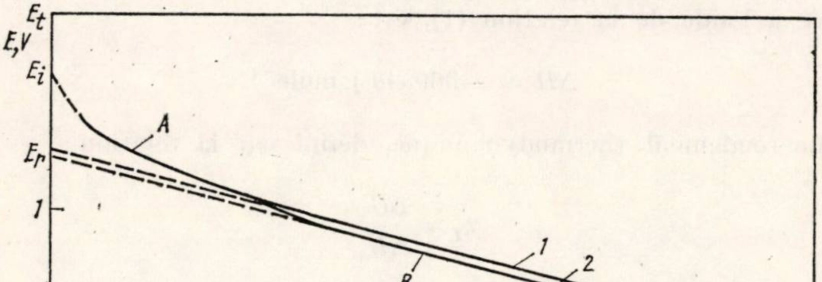

Fig. 3. — Les courbes de décharge de la pile zinc-oxygène.
1 — ΔP_{O_2} = 400 mm Hg, 2 — ΔP_{O_2} = 300 mm Hg.

Les courbes V-i, obtenues pour la pile zinc-oxygène réalisée dans notre laboratoire, sont représentées dans la figure 3.

LE CALCUL DU RENDEMENT DE LA CONVERSION DE L'ÉNERGIE

1. LE RENDEMENT THERMODYNAMIQUE

La réaction chimique caractéristique pour la production du courant dans la pile zinc-oxygène est :

$$\mathrm{Zn} + \tfrac{1}{2}\,\mathrm{O_2} + 2\mathrm{OH^-} \rightarrow \mathrm{ZnO_2^{2-}} + \mathrm{H_2O}$$

L'enthalpie libre (ΔG), à la température de 25°,a, dans cette réaction, la valeur

$$\Delta G = -311410 \text{ j. mole}^{-1}$$

La valeur de l'enthalpie (ΔH) peut être calculée à l'aide de la relation :

$$\Delta H = \Delta G + zF\,T\left(\frac{\partial V}{\partial T}\right)_p \qquad (1)$$

dans laquelle $\left(\frac{\partial V}{\partial T}\right)_p$ représente le coefficient de température de la tension électrique, dont la valeur, pour la réaction analogue $\mathrm{Zn} + 2\mathrm{OH^-} \rightarrow \mathrm{Zn(OH)_2} + 2\mathrm{e^-}$ est de $-1{,}002.10^{-3}$ V. deg.$^{-1}$; la même valeur peut être utilisée, avec une bonne approximation, dans le cas de la pile zinc-oxygène, réalisée dans notre laboratoire. La valeur de l'enthalpie, calculée à l'aide de la relation (1), est :

$$\Delta H = -369040 \text{ j. mole}^{-1}$$

Le rendement thermodynamique, défini par la relation :

$$\eta_T = \frac{\Delta G}{\Delta H} \qquad (2)$$

est de 0,8439 pour la réaction chimique caractéristique à la pile zinc-oxygène, à une température de 25°.

2. LE RENDEMENT ÉLECTRIQUE

Les courbes de décharge V-i, représentées dans la figure 3, offrent une image des phénomènes qui ont lieu pendant le fonctionnement de la pile zinc-oxygène ; l'analyse de ces courbes permet de tirer une série de conclusions intéressantes concernant le rendement de la conversion de l'énergie chimique en énergie électrique. On peut distinguer sur les courbes V-i trois zones :

— *la zone A*, des courants faibles, dans laquelle la courbe V-i présente un décroissement non linéaire, la tangente de la courbe ayant la pente ($-r$),

— *la zone B*, qui présente de l'intérêt pour l'exploitation, dans laquelle la courbe de décharge manifeste un décroissement, généralement linéaire, sa tangente ayant la pente égale à (—R), et

— *la zone C*, des courants à grande intensité, dans laquelle la tension électrique de la pile décroît brusquement avec l'augmentation de l'intensité du courant, zone qui n'intéresse pas l'exploitation.

Sur l'ordonnée des courbes V-i (fig. 3) on peut distinguer les valeurs suivantes de la tension électrique :

— *la tension électrique totale*, E_t, obtenue par l'addition des potentiels des électrodes qui constituent la pile,

— *la tension électrique idéale*, E_i, l'ordonnée à l'origine de la zone *A* des courbes de décharge, tension électrique que l'on obtient lorsque l'intensité du courant est égale à zero, et

— *le tension électrique réelle*, E_r, l'ordonnée à l'origine de la zone *B* des courbes de décharge, tension électrique maximale qui peut être obtenue dans les conditions d'exploitation de la pile.

Entre ces tensions, pendant l'exploitation, s'établissent les pertes suivantes :

— *la perte thermodynamique*, $\Delta E_u = E_t - E_i$, résultée de la transformation incomplète de l'énergie chimique en énergie électrique dans les conditions de fonctionnement (pression, température) de la pile, et

— *la perte électrique*, $\Delta E_p = E_i - E_r$, résultée de l'apparition des phénomènes de polarisation survenus pendant le fonctionnement de la pile.

Entre les données thermodynamiques de la réaction caractéristique pour la production du courant dans la pile zinc-oxygène et ses caractéristiques électriques, il y a les relations suivantes :

$$E_t = -\frac{\Delta H}{zF} \tag{3}$$

$$E_i = -\frac{\Delta G}{zF} \tag{4}$$

$$E_u = E_t - E_i = \frac{\Delta H - \Delta G}{zF} = -\frac{T\Delta S}{zF} \tag{5}$$

Les valeurs calculées pour E_t, E_i et ΔE_u, dans le cas de la pile zinc-oxygène, sont respectivement 1,912, 1,614 et 0,298 V.

On peut définir un facteur thermodynamique (ν) :

$$\nu = \frac{\Delta E_u}{E_t} = \frac{T\Delta S}{\Delta H} \tag{6}$$

qui, dans le cas de la pile zinc-oxygène, a la valeur de 0,1561. Entre ce facteur thermodynamique, le rendement thermodynamique (2) et les tensions électriques E_i et E_t il y a la relation :

$$\eta_T = 1 - \nu = \frac{E_i}{E_t} \tag{7}$$

Dans la zone B des courbes de décharge, zone qui intéresse l'exploitation, la tension varie linéairement en fonction de l'intensité du courant, la pente de cette droite ayant la valeur $(-R)$; l'ordonnée à l'origine (E_r) — la tension électrique en circuit ouvert — dans certaines conditions de pression et de température, lorsque l'intensité du courant tend à zéro — est :

$$E_r = E_i - \Delta E_p \tag{8}$$

et a la valeur de 1,285 V et de 1,260 V, à des surpressions de l'oxygène de 400 et, respectivement, de 300 mm Hg.

De l'équation (8) on peut calculer la perte électrique (ΔE_p), dont la valeur est de 0,329 V et, respectivement, de 0,354 V, dans les conditions mentionnées ci-dessus.

On peut définir un facteur de polarisation (μ) :

$$\mu = \frac{\Delta E_p}{E_i} \tag{9}$$

qui a les valeurs de 0,2037 et, respectivement, de 0,2193.

Le rendement électrique maximal $(\varepsilon_{\max})$ de la pile zinc-oxygène, lorsque l'intensité du courant tend à zéro, est :

$$\varepsilon_{\max} = \frac{E_r}{E_i} = \frac{E_i - \Delta E_p}{E_i} = 1 - \mu \tag{10}$$

et a la valeur de 0,7963 et, respectivement, de 0,7807.

L'intensité maximale du courant produit par la pile — l'abscisse à l'origine de la zone B des courbes de décharge représentées dans la figure 3 — est :

$$I_{\max} = (1 - \mu)\frac{E_i}{R} \tag{11}$$

dans laquelle R représente la pente de la zone B des courbes (fig. 3) et a la valeur de 2,2. Les valeurs de l'intensité maximale des courants produits par la pile réalisée dans notre laboratoire sont de 0,5842 A/cm^2 et de 0,5728 A/cm^2 (rapportées à la surface géométrique de la cathode poreuse), dans le cas de la surpression de l'oxygène de 400 et, respectivement, de 300 mm Hg.

Dans les conditions réelles d'exploitation, on peut considérer, avec une bonne approximation, que l'on obtient un courant :

$$I_{\text{moyen}} = \tfrac{1}{2} I_{\max} \tag{12}$$

qui a la valeur de 0,2921 A/cm² et, respectivement, de 0,2864 A/cm² et, la pile présente un rendement électrique moyen :

$$\varepsilon_{\text{moyen}} = \tfrac{1}{2} \varepsilon_{\max} = \tfrac{1}{2}(1 - \mu) \tag{13}$$

dont la valeur est de 0,3982 et, respectivement, de 0,3904.

Dans les conditions de fonctionnement, la puissance électrique maximale qui peut être fournie dans le circuit extérieur, peut être calculée à l'aide de la relation :

$$P_{\max} = I^2_{\text{moyen}} R = \tfrac{1}{4}(1 - \mu)^2 \frac{E_i^2}{R} \tag{14}$$

et a la valeur de 0,1877 w/cm² et, respectivement, de 0,1805 w/cm².

La tension électrique (E) fournie par la pile zinc-oxygène réalisée dans notre laboratoire, dans les conditions définies par la zone B des courbes (fig. 3), est :

$$E = E_t - \Delta E_u - \Delta E_p - RI \tag{15}$$

dans laquelle E_t représente la tension électrique totale définie par l'équation (3), ΔE_u—la perte de potentiel entropique définie par l'équation (5) et ΔE_p — les pertes par polarisation.

Si l'on définit un coefficient σ qui exprime les pertes par polarisation :

$$\sigma = \frac{\Delta E_p}{E_t} \tag{16}$$

dont la valeur est de 0,172 et, respectivement, de 0,185, pour la pile réalisée dans notre laboratoire ; la valeur du rendement de la conversion de l'énergie chimique en énergie électrique peut être calculée à l'aide de la relation :

$$\eta = \frac{E}{E_t} = 1 - \nu - \sigma - \frac{RI}{E_t} \tag{17}$$

et présente une valeur maximale lorsque l'intensité du courant produit est égale à zéro[5] :

$$\eta_{\max} = 1 - \nu - \sigma = (1 - \nu)(1 - \mu) \tag{18}$$

La valeur du rendement maximal de la conversion de l'énergie dans la pile zinc-oxygène construite dans notre laboratoire est de 0,6719 et de 0,6589, pour des surpressions de l'oxygène de 400 et, respectivement, de 300 mm Hg.

Le rendement de la conversion de l'énergie chimique en énergie électrique est égal au produit obtenu par la multiplication du rendement thermodynamique de la réaction chimique avec le rendement électrique, dans les conditions de fonctionnement :

$$\eta = \eta_T \cdot \varepsilon \tag{19}$$

LE RENDEMENT DE LA CONVERSION DE L'ÉNERGIE DANS LES CONDITIONS DE L'OBTENTION D'UNE PUISSANCE MAXIMALE DANS LE CIRCUIT EXTÉRIEUR

Le décroissement des performances de la pile — effet des polarisations qui apparaissent pendant le fonctionnement de la pile—se manifeste par l'obtention, dans le circuit extérieur, d'un courant réduit par un facteur i :

$$i = \frac{R}{E_i} I \tag{20}$$

relation dans laquelle I est $I_{\max}$ de l'équation (11) lorsque $\mu = 0$. Pour la pile construite dans notre laboratoire, ce facteur de réduction de l'intensité a les valeurs de 0,40 et de 0,39, pour des surpressions de l'oxygène de 400 et, respectivement, de 300 mm Hg.

A ce facteur de réduction du courant correspond un facteur de réduction de la puissance p :

$$p = \frac{4R}{E_i^2} P \tag{21}$$

relation dans laquelle P est $P_{\max}$ de l'équation (14), pour $\mu = 0$.

Entre les facteurs p et i il y a la relation [5] :

$$p = 4i(1 - \mu - i) \tag{22}$$

qui démontre que p est une fonction parabolique de i.

La représentation graphique de cette fonction (fig. 4) nous montre que la valeur minimale du facteur de puissance ($p = 0$) s'enregistre pour les valeurs $i = 0$ et $i_{\max} = 1 - \mu$. La valeur maximale du facteur de puissance ($p_{\max}$), correspondant à la puissance maximale dans le circuit extérieur, est :

$$p_{\max} = (1 - \mu)^2 \tag{23}$$

et a les valeurs de 0,634 et, respectivement, de 0,610 pour la pile zinc-oxygène construite dans notre laboratoire. A ce facteur de puissance ($p_{\max}$) correspond un i moyen :

$$i_{\text{moyen}} = \tfrac{1}{2}(1 - \mu) = \tfrac{1}{2} i_{\max} \tag{24}$$

qui a les valeurs calculées par la relation (20).

Tableau

Caractéristiques thermodynamiques et électriques de la pile

Pile du type	ΔH	ΔG	$T\Delta S$	$E_t = -\frac{\Delta H}{zF}$	$\Delta E_u = -\frac{T\Delta S}{zF}$	$E_i = -\frac{\Delta G}{zF}$
	j. mole^{-1}	j. mole^{-1}	j. mole^{-1}	V	V	V
1. zinc-oxygène (ΔP_{O_2}=400 mm Hg)	−369040	−311410	−57630	1,912	0,298	1,614
2. zinc-oxygène (ΔP_{O_2}=300 mm Hg)						

Dans les conditions de fonctionnement, la pile zinc-oxygène fournira une tension électrique (E), dont l'expression est représentée par l'équation (15) et a les valeurs de 0,642 V et, respectivement, de 0,630 V.

Etant donné les pertes par polarisation, le rendement réel de la conversion de l'énergie réalisé dans la pile construite dans notre laboratoire, dans les conditions de fonctionnement, peut être calculé à l'aide de la relation :

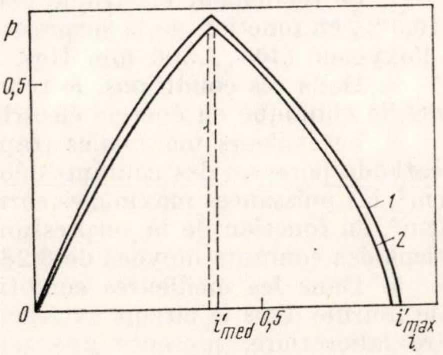

Fig. 4. — La représentation graphique de la fonction parabolique $p = (f)i$ pour la pile zinc-oxygène.
1 – $\Delta P_{O_2} = 400$ mm Hg, 2 – $\Delta P_{O_2} = 300$ mm Hg.

$$\eta_{\text{réel}} = (1 - \nu)(1 - \mu - i) \tag{25}$$

et a les valeurs de 0,3355 et de 0,3298, pour les surpressions de l'oxygène de 400 et, respectivement, de 300 mm Hg.

Le rendement élevé de la conversion de l'énergie chimique réalisé dans la pile zinc-oxygène construite dans notre laboratoire est comparable aux données de la littérature de spécialité pour les piles à combustible et est supérieur au rendement de la conversion de l'énergie réalisée dans les sources classiques de courant.

Les données thermodynamiques et électriques qui caractérisent la pile zinc-oxygène construite dans notre laboratoire sont présentées dans le tableau 1.

CONCLUSIONS

1. Le rendement thermodynamique de la pile du type zinc-oxygène, construite dans notre laboratoire, à cathode poreuse du type DSK activée avec de l'argent, est de 84,39%.

2. Le rendement électrique maximal de la pile est compris entre 78 et 79,6%, en fonction de la surpression d'alimentation de la cathode avec de l'oxygène (400...300 mm Hg).

3. Dans ces conditions, le rendement maximal de la conversion de l'énergie chimique en énergie électrique est compris entre 66 et 67%.

4. Les valeurs maximales (rapportées à la surface géométrique de la cathode poreuse) des courants débités sont comprises entre 0,57 et 0,58 A/cm², les puissances maximales correspondantes étant de 0,18 et de 0,19 W/cm², en fonction de la surpression de l'oxygène. Dans la pratique, on obtient des courants moyens de 0,28 et de 0,30 A/cm².

5. Dans les meilleures conditions d'exploitation (puissance maximale fournie dans le circuit extérieur), la pile zinc-oxygène réalisée dans notre laboratoire, présente une tension électrique de 0,63...0,64 V. Dans ces conditions, le rendement électrique présente la valeur de 40% et la pile zinc-oxygène réalise une conversion de l'énergie chimique en énergie électrique avec un rendement de 33...34%.

SIMPLE HMO-CALCULATIONS ON SOME N-HETEROCYCLIC LIGANDS OF ANALYTICAL IMPORTANCE*

SHYAMA P. SINHA

Department of Chemistry, University of Malaya
Kuala Lumpur, Malaysia

Received September 7, 1972

Simple Hückel Molecular Orbital calculations were performed on a number of N-heterocyclic ligands of analytical importance, i.e., six isomeric dipyridyls and three phenylpyridines. The effect of variation of α_N on the first $\pi \rightarrow \pi^*$ transition energy has been investigated. The best value of h_N for each compound was obtained by comparing the observed transition energy (ν_{obs}) of the compound with that calculated (ν_{calc}) by assuming various values of h_N. A linear correlation between ν_{obs} and ν_{calc} was obtained.

The dipyridyls, in particular, the 2,2′-isomer form complexes with a variety of metal ions.[1–3] The analytical uses of 2,2′-dipyridyl and its derivatives are well known.[4] We are currently investigating the 1,10-phenanthroline and dipyridyl complexes of the lanthanides by NMR spectroscopy.[5] We have observed high field shift of all protons of phenanthroline and both high and low field shifts for 2,2′-dipyridyl[6] due to complexation of these ligands with lanthanide ions. In an attempt to understand these shifts, it is thought that an analysis of the charge density on various atoms of the ligand might be useful. Often the chemical shifts of protons can be correlated to the charge densities on the carbon atoms to which they are bounded.[7] With this in mind we started simple Hückel MO-calculations on the six isomeric dipyridyls and the related phenylpyridines (Fig. 1).

ISOMERIC DIPYRIDYLS

Like biphenyl, all isomeric dipyridyls present a 12 π-electron system, each N-atom like the CH-group contributing one π-electron to the aromatic ring. In the HMO method, the heteroatoms (here nitrogen) may be treated by appropriate change in the empirical α and β parameters associated with each atom and bound in the secular determinant $|H_{ij} - S_{ij}| = 0$ as:

$$\alpha_N = \alpha_0 + h_N\beta_0 \tag{1}$$

and

$$\beta_{CN} = k_{CN}\beta_0 \tag{2}$$

where α_0 and β_0 are the Coulomb integrals and the resonance integrals of (usually) benzene, respectively, and the other symbols have their usual meaning. It remains now to choose the values of h_N and k_{CN} and solve the secular determinant for energies and orbital coefficients and to calculate the charge densities bond order etc.

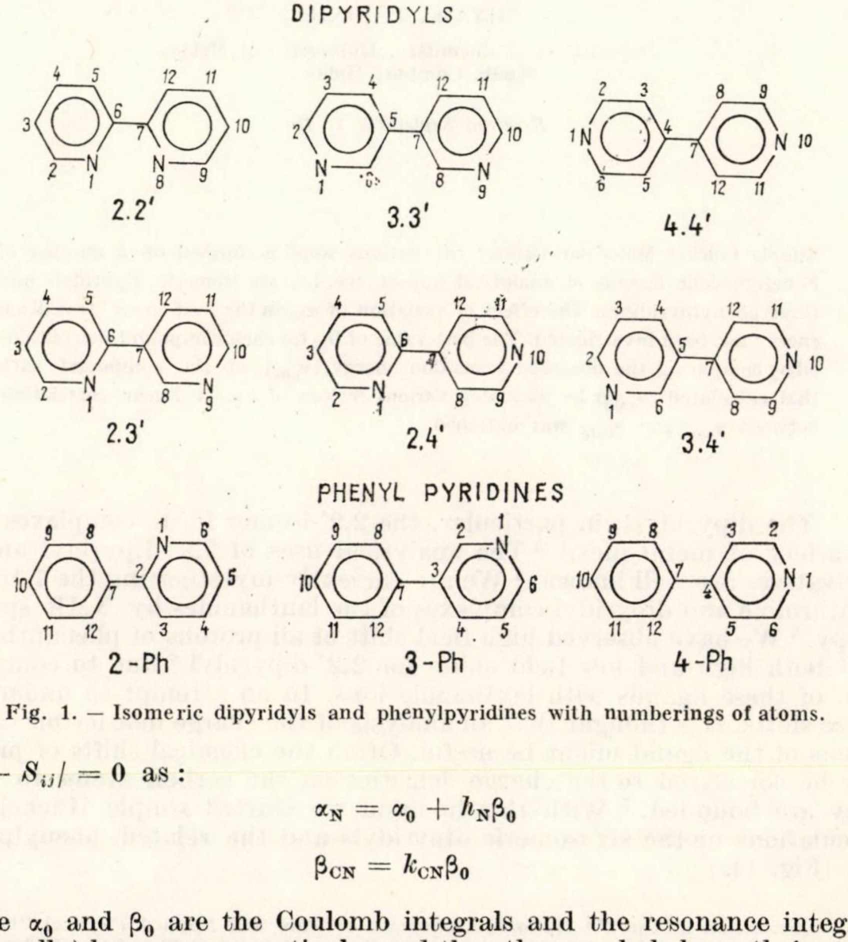

Fig. 1. — Isomeric dipyridyls and phenylpyridines with numberings of atoms.

The values of the parameters h_N and k_{CN} are usually assigned as "inteligent guesses" from studies on variety of similar compounds. It is commonly assumed that the value of k_{CN} is 1 or very near to 1 and the calculated charge distribution is rather insensitive to small variation in this parameter.[7] Throughout this study we have used $k_{CN} = 1$.

A survey of the parameter h_N, however, shows a wide variation of the values adopted for various compounds by various authors. Brown and coworkers[8-10] prefer to use $h_N = 0.5$ (for N contributing a core charge of $+1$) and $h_N = 2.0$ (for N contributing a core charge of $+2$) for neutral and protonated pyridine systems, while Mason[11] obtained good correlation by using $h_N = 0.6$. Yet, other values of h_N ranging between 0.9 and 1.2 have been used by other authors.[12-14]

Table 1

The calculated $\pi \to \pi^*$ transition energies from the highest occupied orbital (HOO) to the lowest unoccupied orbital (LUO) for the isomeric dipyridyls for a set of h_N values

h_N	2,2′	3,3′	4,4′	2,3′	2,4′	3,4′
0.1	1.4064	1.4085	1.4093	1.4077	1.4075	1.4086
0.2	1.3985	1.4068	1.4097	1.4034	1.4027	1.4070
0.3	1.3865	1.4036	1.4101	1.3964	1.3949	1.4043
0.4	1.3697	1.3993	1.4107	1.3871	1.3844	1.4007
0.5	1.3503	1.3935	1.4115	1.3769	1.3719	1.3962
0.6	1.3288	1.3862	1.4123	1.3631	1.3576	1.3908
0.7	1.3059	1.3776	1.4130	1.3491	1.3491	1.3848
0.8	1.2822	1.3675	1.4136	1.3344	1.3252	1.3782
0.9	1.2581	1.3562	1.4139	1.3192	1.3082	1.3710
1.0	1.2341	1.3440	1.4142	1.3039	1.2906	1.3634
1.2	1.1872	1.3174	1.3661	1.2734	1.2558	1.3477
1.4	1.1426	1.2893	1.3219	1.2441	1.2217	1.3315
1.5	1.1216	1.2754	1.3012	1.2302	1.2054	1.3233
1.6	1.1013	1.2651	1.2814	1.2168	1.1895	1.3153
1.8	1.0634	1.2345	1.2444	1.1913	1.1594	1.2995
2.0	1.0289	1.2089	1.2107	1.1680	1.1314	1.2845

All energies are in terms of β-units. The HOO → LUO transition in biphenyl has been calculated to be 1.4092 β, and $\nu_{obs} = 40000\ cm^{-1}$.

The first objective of our study was to determine the best value of the parameter h_N for the dipyridyl systems and to see if there exists a unique value of the parameter for all isomeric dipyridyls.

The orbital coefficients, energies, electron densities and bond orders for all six isomeric dipyridyls were calculated[15] for a wide range of values (0.1 — 2.0) of the parameter h_N. In Table 1, the calculated energies for the first $\pi \to \pi^*$ transition from the highest occupied orbital (HOO) to the lowest unoccupied orbital (LUO) for a set of h_N values are presented,

and these data are plotted in Fig. 2. Except for the case of 4,4′-isomer, the calculated transition energy is a monotonic function of the parameter h_N (Fig. 2). At lower values of h_N, the transition energies approached (Fig. 2) that of biphenyl (1.4092β).

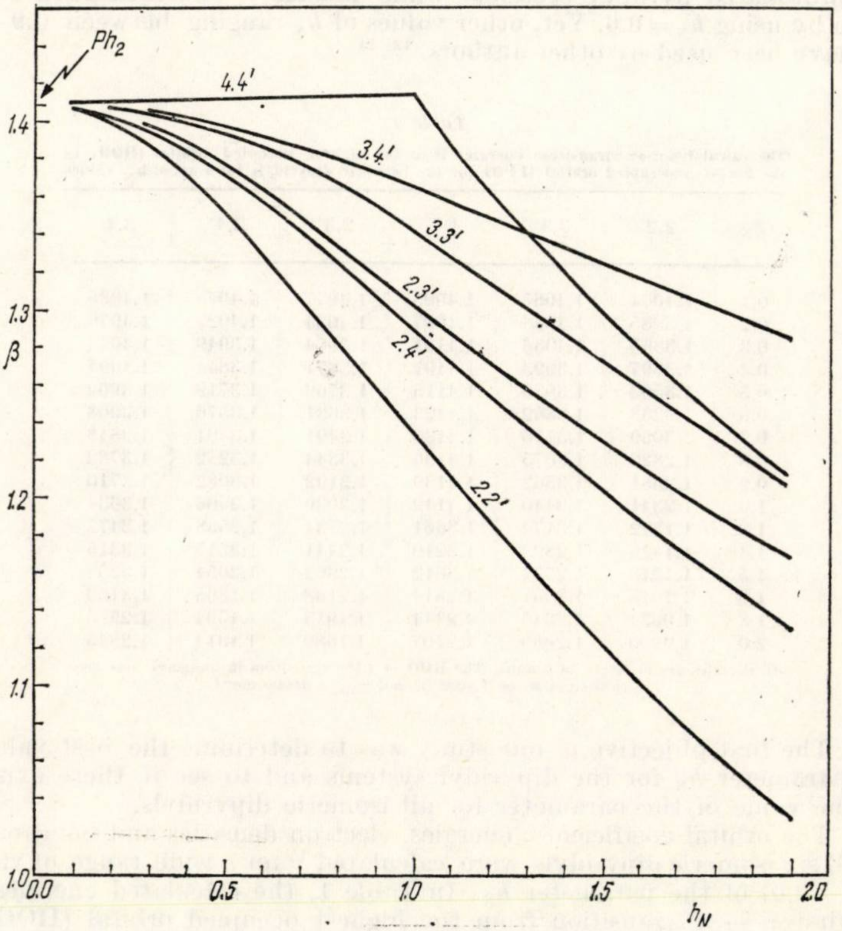

Fig. 2. — The variation of the calculated HOO → LUO energies with h_N.

Studies on aromatic hydrocarbons show [16] a good linear correlation between the observed first π→π* transition energy and the calculated HMO energy difference (E in β units between HOO and LUO :

$$\nu_{obs}\,(\mathrm{cm}^{-1}) = 19020\ (E\beta) + 10520 \qquad (3)$$

At least for one heterocyclic ligand [17] (i.e. 8-hydroxyquinoline) this equation was assumed to be valid. A correlation of the experimentally

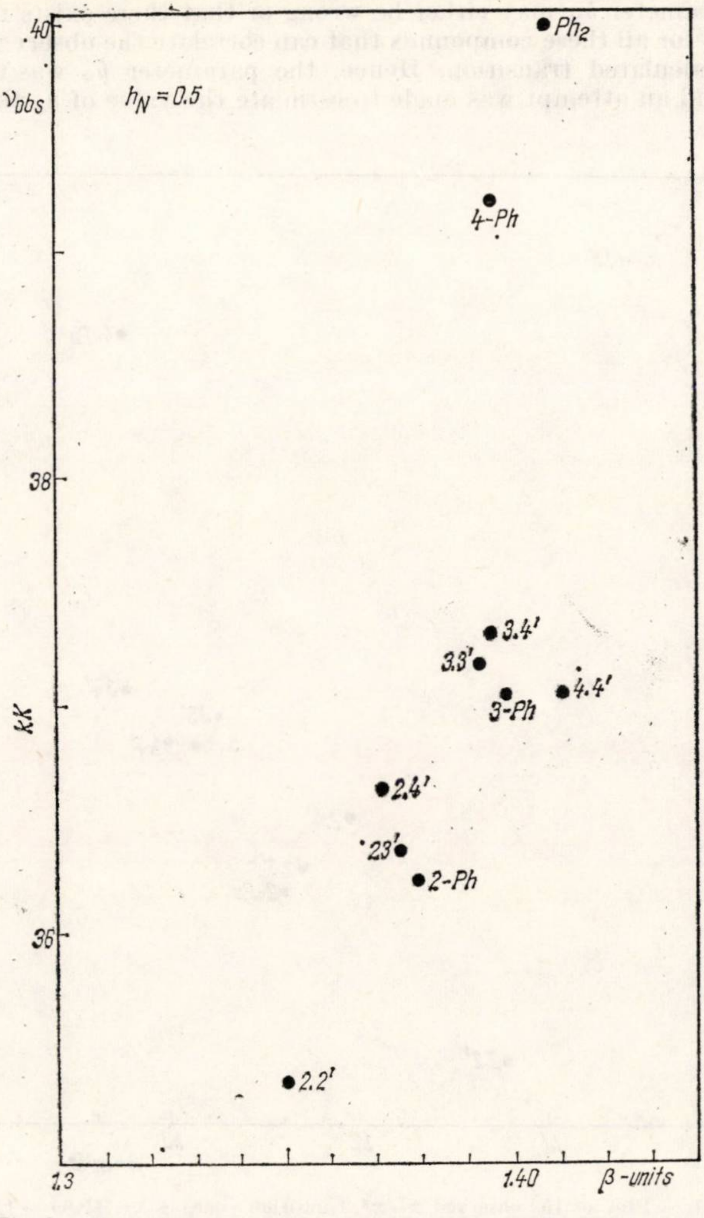

Fig. 3. — Plot of the observed $\pi \rightarrow \pi^*$ transition energies vs. HOO→LUO energies for a value $h_N = 0.5$.

observed first transition (ν_{obs}) and E for the six isomeric dipyridyl and three phenylpyridines using selected values of h_N (i. e. 0.5, 1.0, 1.5) does show wide scatter (Figs. 3 — 5). It is assumed that the choice of the values for the parameter h_N may either be wrong or that there exists no unique value of h_N for all these compounds that can correlate the observed spectra and the calculated transition. Hence, the parameter h_N was treated as variable and an attempt was made to estimate the value of h_N that would

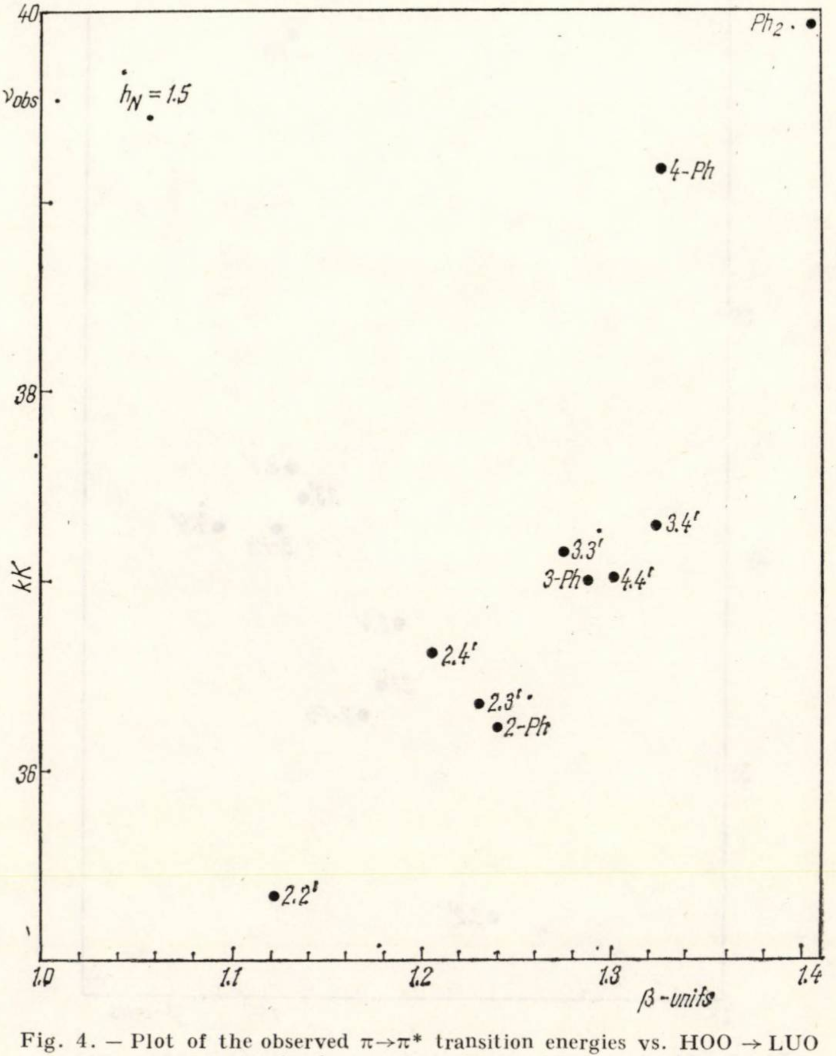

Fig. 4. — Plot of the observed $\pi \rightarrow \pi^*$ transition energies vs. HOO → LUO energies for a value of $h_N = 1.0$.

give the best fit for the observed spectrum of a compound. The following approach was made.

The dipyridyls and phenylpyridines were considered to be ring-substituted biphenyl, which was taken as the reference compound. It was further assumed that the two N-atoms in each dipyridyl were equivalent and could be represented by the same h_N parameter. The dimensionless quantity $(E_b - E_d)/E_b$, where E_b = the HOO→LUO transition in biphenyl (1.4092 β) and E_d is the corresponding transition in dipyridyls and phenylpyridines, was calculated for each value of h_N and a plot was made for each compound. Next the shift of the observed transition[18] for the compound with respect to biphenyl $(\nu_b - \nu_d)/\nu_b$ (ν_b = transition in biphenyl = 40000 cm^{-1}) was calculated. The value of the parameter h_N was then read off the plot, where the value of $(\nu_b - \nu_d)/\nu_b$ corresponds to that of

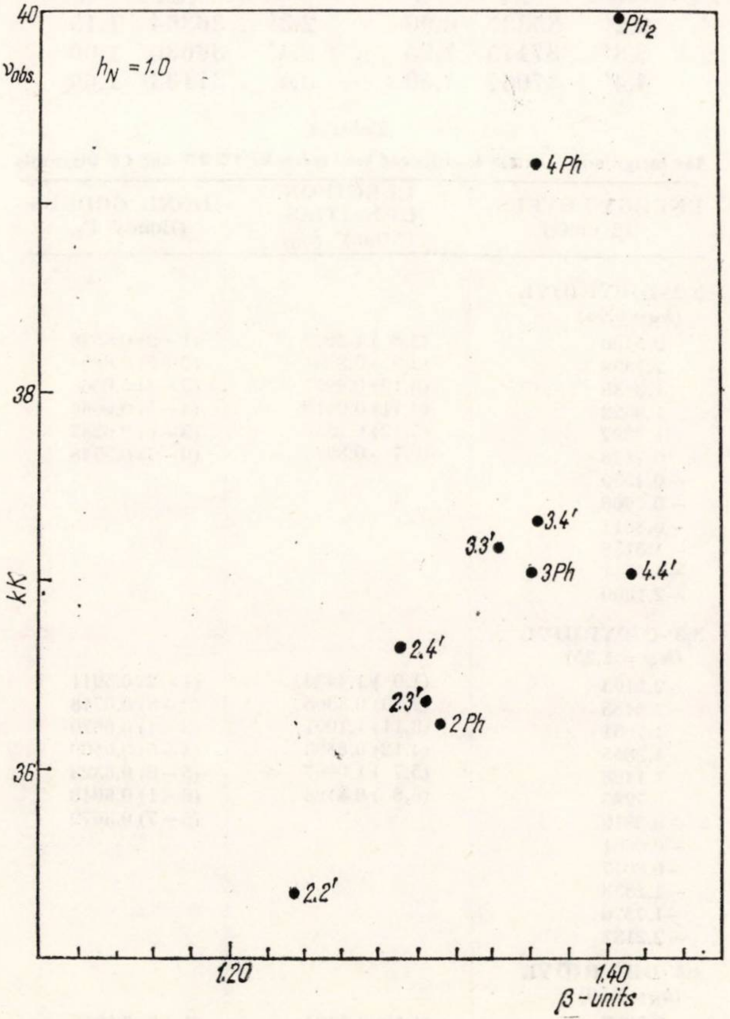

Fig. 5. — Plot of the observed π→π* transition energies vs. HOO→LUO energies for a value of $h_N = 1.5$.

Table 4

Parameters for isomeric phenyl pyridines

Isomer	ν_{obs} (cm^{-1})	$(\nu_b - \nu_d)/\nu_b$	h_N	Calculated E_β	E_β predicted from eq .4
2-Ph	36232	0.0942	1.25	1.2745	1.276
3-Ph	37037	0.0741	1.40	1.3026	1.304
4-Ph	39216	0.0196	0.75	1.3820	1.380

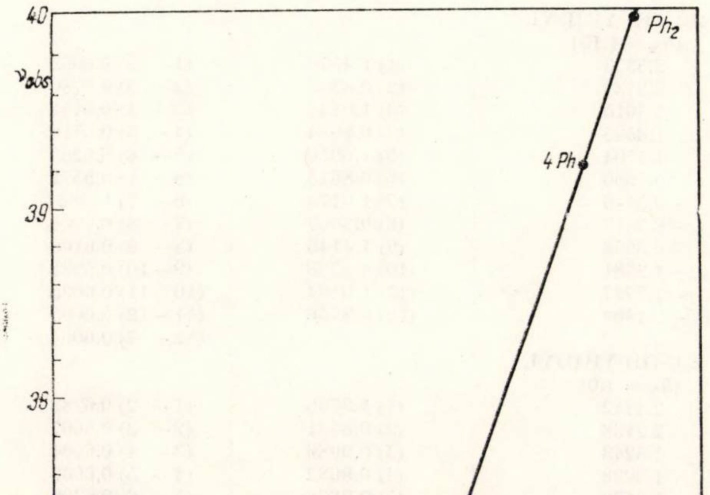

Fig. 6. — Correlation between the observed $\pi \rightarrow \pi^*$ transition energies and the calculated (see text) HOO → LUO energies for isomeric dipyridyls and phenylpyridines.

energy (ν_{obs}) which yields a linear correlation and the least square line is best described by:

$$\nu_{obs}(\mathrm{cm}^{-1}) = 28597\ (E_{\beta}) - 262 \qquad (4)$$

PHENYLPYRIDINES

An approach similar to the isomeric dipyridyls was made for the three phenylpyridines (Fig. 1). The h_N values and the calculated E values are reported in Table 4. It was of interest to test the validity of eq. 4, in the case of phenylpyridines. The predicted HOO→LUO transition energies for the phenylpyridines agree very closely (Table 4) to those calculated by using the derived h_N parameters.

A final correlation between ν_{obs} and calculated HOO→LUO transitions for all nine compounds resulted in a linear plot (Fig. 6) described by the following least square equation:

$$\nu_{obs}(\mathrm{cm}^{-1}) = 28400\ (\mathrm{E}_{\beta}) - 2.9 \qquad (5)$$

The average deviation between ν_{obs} and ν_{calc} values for all nine compounds is of only 34 cm^{-1}. It is gratifying to see that biphenyl also falls on this linear plot.

In conclusion we annotate that the very imprecise nature of the parameter h_N does not warrant the use of any specific value for the correction of the Coulomb parameter, at least in the case of the dipyridyl and phenylpyridine systems. In specific correlations (as with UV spectral data presented here) it is advisable to adjust the value of h_N for best fit.

ON THE OSCILLATION SPECTRUM OF DIMETHYL SULPHOXIDE (DMSO) IN SOLUTION

LIGIA SINGUREL and G. SINGUREL
Spectroscopy Laboratory, "Al. I. Cuza" University,
Iaşi, str. 23 August 11, Romania

Received July 3, 1972

Raman lines parameters of DMSO in carbon tetrachloride, chloroform, water, phenol, acetic and chloroacetic acid were studied. The parameter variation was interpreted as the manifestation of molecular interactions which appear in the studied solutions. For the active solvents a Raman line appeared in close vicinity of the Raman line belonging to the S = O-oscillation which has been assigned to the complex formed by the hydrogen bond. In order to verify the proposed interaction type, IR spectra of DMSO in solvents containing hydroxylic group were recorded. Besides the OH-free oscillation band there appeared a large band with smaller frequency, characteristic of the complex formed by the hydrogen bond. The interaction energy was calculated and a linear relationship between the acidity constants of the used solvents and $\Delta\nu_{OH}$ and $\Delta\nu_{S=O}$ shifts was established.

INTRODUCTION

The Raman spectrum of DMSO was first investigated by Vogel-Hogler.[1] This work contains some data in connection with the degree of depolarization ρ, but because the method of their determination is not described, it is not clear if these represent the real values of ρ. The data on the structure of these molecules, as well as the theoretical investigation of their oscillations are given in,[2] where the IR-spectrum of DMSO-molecule is also presented.

The solvent effect on the band of S = O-oscillation has been studied in the IR-domain in several works.[3–10] In,[11] Selvarajan has investigated the Raman spectra of DMSO mixtures with some liquids, using the method of photographical recording, which did not allow to study the variation of all Raman line parameters. Likewise, in this work, only the changes in the S = O-frequency of DMSO in used solvents are given.

In this work, the results of the change in line parameters for DMSO in carbon tetrachloride, chloroform, water, phenol, acetic and chloroacetic acid solutions with different concentrations, as well as the variations occurred in the OH-oscillation domain of IR-absorption of the DMSO mixtures with compounds containing hydroxylic group (alcohol, water, phenol, and cresol) are presented.

EXPERIMENTAL

Raman line shape was recorded photoelectrically with a grating spectrometer having a dispersion of 6.7Å/mm. As exciting source, a Hg-low pressure lamp was used. The exciting line was of 4368 Å. Accuracy in the frequency determination was of ± 1 cm^{-1}. Integral intensity (I_∞) was measured with a planimeter which gave the area of the spectral line contour. The comparison was made with the band 802 cm^{-1} of the cyclohexane, the integral intensity of which was considered equal to 500 units, while the intensity in maximum was taken equal to 250 units.[12] In the case of solutions, the integral intensity was taken per mol and was expressed in the relative units, where the intensity of the Raman-band of the pure DMSO was considered equal to 100 units. In this case, for the intensity of the bands, the corrections determined by the refraction index variations were introduced. The concentration of the solutions is given as the ratio between the numbers of molecules of DMSO and numbers of the molecules of the solvent. During the recording of spectra the temperature was 25°. The error in the measurement of the integral intensity varied between 5 and 15%, depending on the line character. The line width was corrected by the errors caused by the apparatus split or exciting line. The error in line width determination was of 5%. The degree of depolarization was measured by using the method described by Edssall and Wilson.[13] Using the gauge graph, real values of ρ were obtained.

IR — absorption spectra were obtained by using the IKS-14 spectrophotometer; because only the range of the OH-oscillation was studied, LiF prisms were used. The error in determination was of 3 — 5 cm^{-1} for the narrow bands and of 5 — 15 cm^{-1} for wide bands, including here the error in the calibration curve.

RESULTS AND DISCUSSION

In order to measure the modifications in the Raman line parameters of DMSO under the influence of molecular interaction forces, frequencies, widths, integral intensities, intensities in maximum and the depolarization degree of the Raman lines for DMSO were measured. Their values are given in Table 1.

2 915	C-H	8	—	—	0.06
3 000	C-H	22	—	—	0.8

By passing DMSO in solved state, the changes in the Raman line parameters depend on the solvent nature and the type of the oscillation. These changes may by seen in Table 2. As was to be expected, frequency and line width modifications are more prominent when the solvent is more active. The changes in the parameters of the line 1042 cm^{-1} belonging to S = O valence oscillation are taken into account. These changes have a maximum value for all solvents thus indicating that S = O group in DMSO molecule is the group most influenced by the solvent molecules. It should be pointed out that for this line the wave number increases when DMSO solves in CCl_4. This modification is, probably, caused by the fact that the DMSO molecules interact and by solving in CCl_4 pass in the monomer. Large width of the 1042 cm^{-1} and 3000 cm^{-1} in pure DMSO and the narrowing of the width of these lines for the solution of the DMSO in CCl_4 come in support of this supposition. The integral intensity of the DMSO bands in the solutions changes very little. This indicates that the tensor of the polarization derivative of the molecule of DMSO is not strongly modified when the DMSO solves.

As the solvent acidity increases, the complex formation between DMSO and solvent leads to a stronger modification in frequency of S=O-oscillation. Thus in solutions of DMSO with chloroform and water this line is shifted to the larger wave number, the shift being three times larger in water than in chloroform. Because in chloroform and water the Raman line splitting was not observed, it is supposed that the interaction has a dipole — dipole and partly ionic character.

In stronger solvents, as acetic and chloroacetic acids, the line of 1042 cm^{-1} is split in two components of 1015 cm^{-1} and 1050 cm^{-1}. Investigations about the concentration variations show that by the decrease in DMSO content the first line intensity increases and the second one decreases (Fig. 1). This effect shows that 1015 cm^{-1} line belongs to the S = O-oscillation of the DMSO molecule bound in the complex with solvent molecule. Line of 1050 cm^{-1} belongs to the free DMSO molecules, a fact which comes in favour of the supposition concerning the association of DMSO molecules between themselves. In the last case, at the interaction of the DMSO molecules with acetic and chloroacetic acids, DMSO com-

plex unbinds, fact spectrally manifested by the appearance of Raman line of 1050 cm^{-1} belonging to the S=O free oscillation. In DMSO solutions with acetic and chloroacetic acids, the lines 332 cm^{-1} and 699 cm^{-1} are also splitting. Thus, in the solution of DMSO with acetic acid the line of 306 cm^{-1} appear while with chloroacetic acid that of 294 cm^{-1} appear. The stronger decrease in frequency in the last case indicates an increase in the interaction.

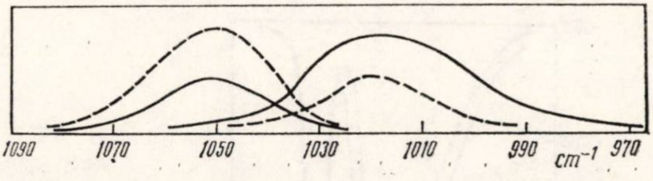

Fig. 1. — The intensity variation of lines belonging to S = O-oscillation of DMSO and the formed complex with acetic acid function of DMSO concentration in acid.

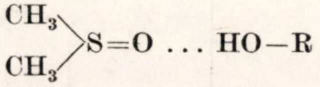
In both cases the appearance of new lines is caused by the complex formation. It should be emphasized that the position change of the S = O and C — S = O lines in solution is similar, indicating that these groups are to the same extent affected by intermolecular forces. As for the solvent, in the last two cases it interacts by the hydroxylic group, because it is more active and an interaction of hydrogen bond type takes place :



$$\begin{matrix} CH_3 \\ CH_3 \end{matrix}\!\!> S=O \ldots HO-R$$

The verification of this supposition was done by the investigations in the IR-absorption range of the DMSO solutions containing hydroxylic compounds. The change in line parameters for the OH-oscillation range in the solutions of DMSO with the butyl-, *n*-propyl-, ethyl-, methyl alcohol, water *ortho*-cresol, *para*-cresol and phenol were studied. The investigations were carried out in the ternary solutions, a solvent being inert, in order to permit the alcohol dissociation in monomers. The hydroxylic compound concentration was smaller than 10^{-2} mol/l, thus assuring the presence of the alcohol molecule in the monomer form. This effect was spectrally verified (the appearance of a narrow band of wave number 3600 cm^{-1}). When, in the above mixture, DMSO is present in very small quantities (10^{-2} mol/l), a very broad and intense band appears in the spectral region with small wave numbers. It belongs to the complex formed between hydroxylic compound and DMSO. This fact can be confirmed if we maintain the hydroxylic compound concentration constant and modify the DMSO concentration; then the intensity of the broad band decreases and the monomer band intensity increases. This is very well illustrated in Fig. 2. The complex band position and intensity depend on the interaction intensity between DMSO and the compound containing OH-group. In Table 3 are indicated the frequency values of monomer and complex for DMSO solutions in various substances. The values of

$\Delta\nu_{OH}$, being experimentally measured and using the linear relation between $\left(\frac{\Delta\nu}{\nu}\right)_{OH}$ and interaction energy E: $\left(\frac{\Delta\nu}{\nu}\right)_{OH} = kE$, experimentally found by Badger-Bauer [14] and theoretically verified by Sokolov, [15] the interaction energy was calculated. The constant k was taken after Sokolov of 1.6×10^{-2}mol/kcal. The obtained values of the interaction energy are presented in Table 3 and are in agreement with those given in [16] obtained by calorimetrically determinations. These values indicate the presence of hydrogen bond.

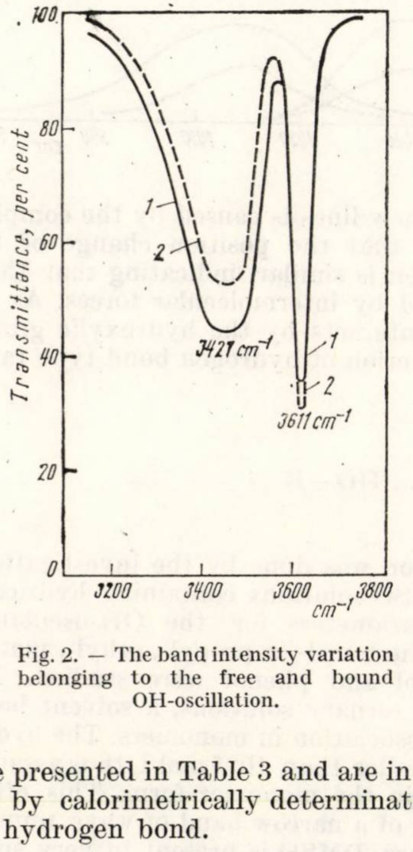


Fig. 2. — The band intensity variation belonging to the free and bound OH-oscillation.

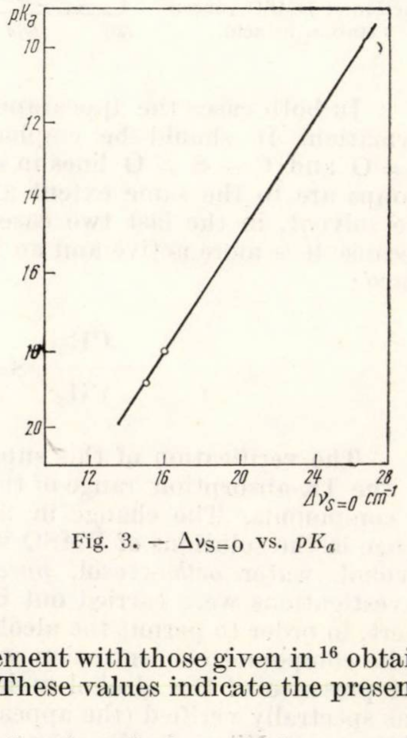

Fig. 3. — $\Delta\nu_{S=O}$ vs. pK_a

In the present work we searched for the relation which may exist between $\Delta\nu_{OH}$ and acidity constant K_a of the solvents:

$$pK_a = -\lg K_a = -\lg \frac{A^+H^-}{AH}$$

The results of these measurements are presented in Table 3. As was already stated, there exists a linear relation between $\Delta\nu_{OH}$ and pK_a, which,

THE STUDY OF THE DECOMPOSITION OF ORGANIC HYDROPEROXIDES ON CATION EXCHANGERS. II[1]

DECOMPOSITION OF CUMENE HYDROPEROXIDE ON FINE GRANULATED VIONIT CS-1 IN STATIC CONDITIONS

J. VODNÁR

Babeş-Bolyai University, Department of Chemical Technology,
str. Arany János, 11, Cluj, Romania

Received March 11, 1972

The paper presents experimental results, obtained by the decomposition of cumene hydroperoxide into phenol and acetone by acidic catalysis, in static conditions. Fine granulated Vionit CS-1 cation exchanger has been used as catalyst; its chemical and some physical properties were described in a previous paper.[1] The cation exchanger, as catalyst, was activated by a method patented by the author.[2] This catalyst proved to be very efficient. The highest conversion of cumene hydroperoxide into phenol (96 – 99 %) can be obtained on low temperature, with a low concentration of hydroperoxide in the samples subjected to decomposition.

The experimental results described in this paper are concerned with the catalytic decomposition of cumene hydroperoxide by using activated,[2] fine granulated Vionit CS-1 cation exchanger. As reaction products phenol and acetone were obtained. This is, actually, the best method of producing these substances in high quantities.

In a previous paper[1] the data obtained by the decomposition of cumene hydroperoxide on the same cation exchanger were discussed, but this was used in its original (industrially realized) granulation, at temperatures higher than 25°. On the basis of these conclusions it seemed important to study the decomposition process on fine granulated catalyst, at lower temperatures.

EXPERIMENTAL

In the paper there are presented the results obtained on the decomposition of cumene hydroperoxide on activated, fine granulated Vionit CS-1 cation exchanger. The granulation of the catalyst is 0.25 – 0.50 mm; its chemical characteristics were described in another paper.[1]

---

[2] J. Vodnár and G. J. Kulcsár, Romanian Patent, **49.842** (1967).

Experiments have been carried out in static conditions, using 0.1 g of catalyst and 20 ml of hydroperoxide samples. The reaction mixture was stirred vigorously. Temperature was maintained constant by means of a Wobser U_8 ultrathermostat. Tests for dosing hydroperoxide and phenol are periodically taken from the reaction mixture. The applied analytical methods are described in a printed paper. [3]

RESULTS AND DISCUSSION

Decomposition of cumene hydroperoxide has been studied depending on the following parameters : temperature, hydroperoxide content of the samples, quantity of the catalyst, water content of the reaction mixture and the generated heat (using different hydroperoxide content of the samples). Kinetic curves are designed at six temperatures, between 11.8 and 22.5°.

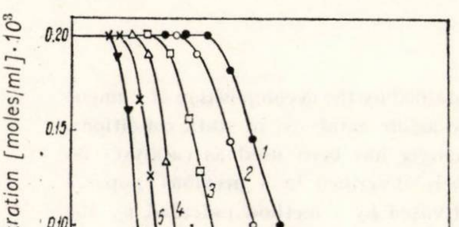

Fig. 1. – Kinetic curves at different temperatures. Quantity of the catalyst, 0.1 g :

1, 11.8°; *2*, 13.5°; *3*, 15.25°; *4*, 17.5° *5*, 20.5°; *6*, 22.5°.

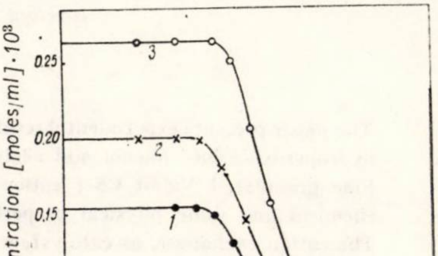

Fig. 2. – Kinetic curves by different initial hydroperoxide concentrations. Temperature, 11.8° :

1, 0.1546 (mole/ml)·10³; *2*, 0.200 (mole/ml)·10³; *3*, 0.2633 (mole/ml)·10³.

The experimental results are illustrated in figures 1 – 8.

The curves of figure 1 illustrate the results obtained by the decomposition of cumene hydroperoxide in accordance with the reaction time, at different temperatures. The time, necessary for total decomposition at 22.5° is no more than 28 minutes, but it increases much if the temperature is 11.8°, when the total decomposition is realized in about 95 minutes.

The process has an autocatalytic character at all temperatures.

Figure 2 contains the graphs designed on the basis of results obtained by the decomposition of samples with different initial hydroperoxide contents : 0.1546 ; 0.200 and 0.2633 mol·l^{-1}. Temperature was maintained constant at 11.8°. The curves of figure 2 show that the decomposition has a long induction period (about 40 minutes). The time necessary for the decomposition of cumene hydroperoxide is nearly equal in all cases (95 – 100 minutes).

---

[3] J. Vodnár, *Rev. Roumaine Chim.*, **15**, 1947 (1970).

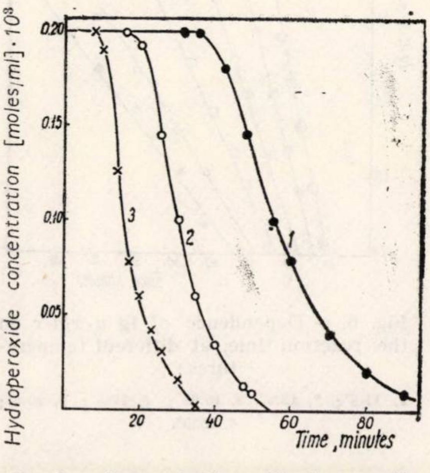

Fig. 3. – Concentration of hydroperoxide in accordance with the reaction time, using different quantities of catalyst. Temperature 11.8°.

1, 0.1 g; 2, 0.2 g; *3*, 0.3 g.

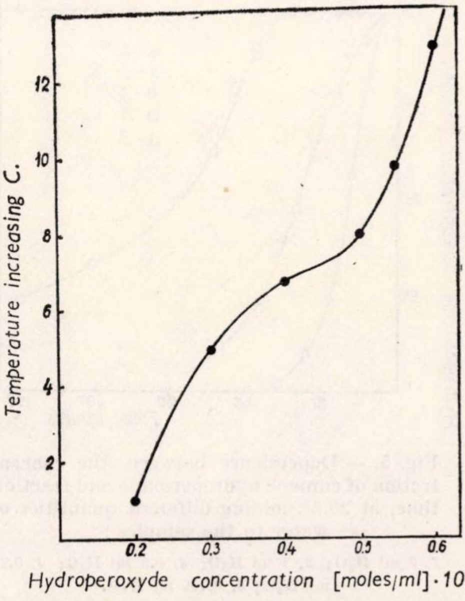

Fig. 4. – Dependence between the increases of the temperature and initial hydroperoxide content of the samples. Temperature 39.8° and the quantity of the catalyst 0.5 g.

In the following experiments the temperature was 11.8° and the quantity of the used catalyst was as follows : 0.1 ; 0.2 and 0.3 g. The results are illustrated in figure 3 ; we can observe that the induction period decreases quickly with the quantity of the catalyst, from 35 min by 0.1 g to 8 min by 0.3 g catalyst.

The decomposition process is exotermic and the heat of the reaction can overheat the mixture to the boiling point of acetone, which troubles the process. With a view to determine the increase of the temperature in the decomposition of the samples, with different cumene hydroperoxide content, there were made a series of experiments illustrated in figure 4. The temperature was 39.8°.

In figure 4 there are represented the increases of temperature in accordance with initial cumene hydroperoxide content of the samples. Temperature increases suddenly when the hydroperoxide content of the samples is more than 0.45 mol·l^{-1}. Consequently, the initial hydroperoxide concentration could not exceed this value. In other case, the condensation of phenol with acetone occurs, yielding resinous substances.

In the last series of experiments, the effect of the water on the activity of the catalyst was studied. We can state that when we work at 20.5°, 1 ml of water causes a total inactivation of 0.2 g catalyst (see figure 5), but a quantity of 0.25 ml water permits decomposition to take place with enough high rate.

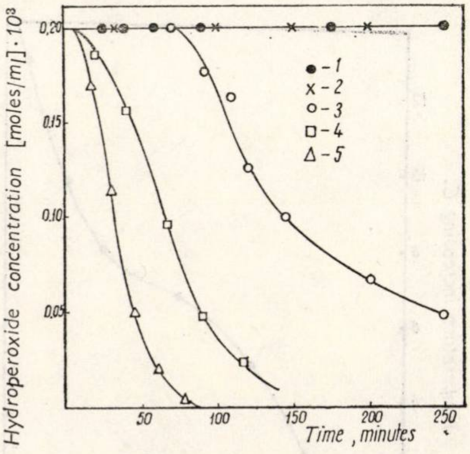

Fig. 5. — Dependence between the concentration of cumene hydroperoxide and reaction time, at 20.5°, adding different quantities of water to the samples :

1, 2 ml H_2O; *2*, 1 ml H_2O; *3*, 0.5 ml H_2O; *4*, 0.25 ml H_2O; *5*, 0.125 ml H_2O.

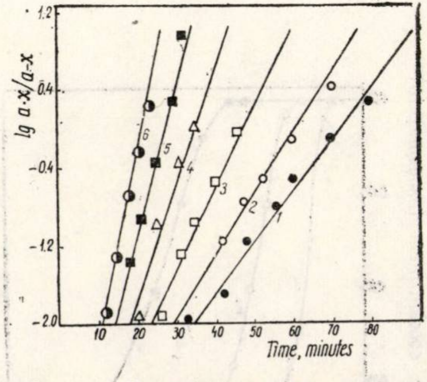

Fig. 6. — Dependence of lg $a \cdot x/a\text{-}x$ on the reaction time, at different temperatures :

1, 11.8°; *2*, 13.5° *3*, 15.25°; *4*, 17.5°; *5*, 20.5°; *6*, 22.5°.

This is a technologically important statement, because it makes possible the reactivation of the catalyst by washing it with the mixture obtained by decomposition.

On the basis of the experimental results obtained, the activation energy, enthalpy, entropy and the activation free enthalpy were determined.

The kinetics of the decomposition process can be designed by the following relation

$$\frac{dx}{dt} = k(a - x)x$$

The integrated form of this relation

$$k \cdot t = \frac{1}{a} \cdot \ln a \cdot x/a - x$$

made possible the linearization of the kinetic curves and the calculation of k values (see figure 6) by representing the values of $\lg a \cdot x/a\text{-}x$ in accordance with the reaction time.

The apparent activation energy of the decomposition process, as deduced from pairs of lg k and $1/T$ values, corresponding to six temperatures (see figure 7) becomes 21 kcal/mole.

Applying the k values, some other kinetic data ($\Delta H^{\ddagger}$; $\Delta S^{\ddagger}$ and $\Delta G^{\ddagger}$), were calculated by representing the pairs of lg k/T and $1/T$ (see figure 8), using the relation

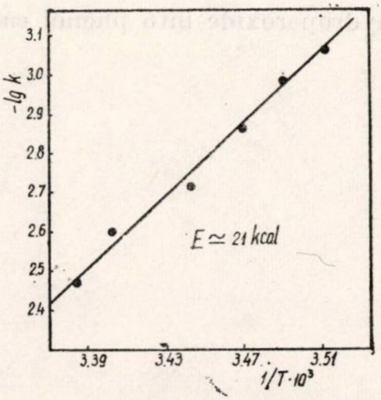

Fig. 7. – Dependence of lg k values on $1/T$.

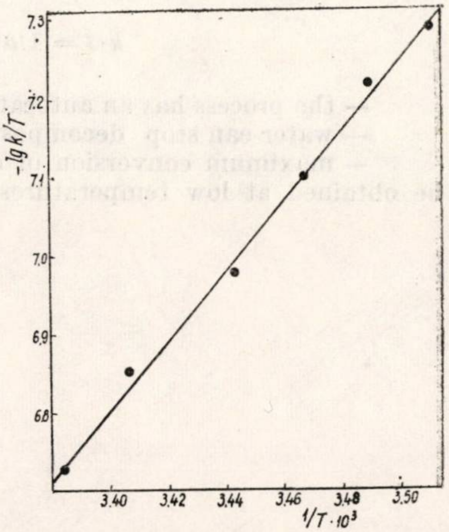

Fig. 8. – Dependence of lg k/T values on $1/T$.

$$\lg\frac{k}{T} = \lg\frac{k}{h} + \frac{\Delta S^{\ddagger}}{2.303\cdot R} - \frac{\Delta H^{\ddagger}}{2.303\cdot R\cdot T}$$

The calculated data are:

$$\Delta H^{\ddagger} = 20.57 \text{ kcal/mole}$$

$$\Delta S^{\ddagger} = -8.37 \text{ cal/K°}$$

$$\Delta G^{\ddagger} = 22.98 \text{ kcal/mole}$$

CONCLUSIONS

Decomposition of cumene hydroperoxide on cation exchanger Vionit CS-1 (fine granulated and activated [2]) has been studied in order to obtain phenol and acetone. We can state that:

— the catalyst used is perfectly fit to decomposition of cumene hydroperoxide;

— the kinetics of the process can be designed by the relation:

$$k \cdot t = 1/a \cdot \ln a \cdot x/a - x;$$

— the process has an autocatalytic character;

— water can stop decomposition;

— maximum conversion of cumene hydroperoxide into phenol can be obtained at low temperatures.

DIE STRUKTUR DES MIT LITHIUM UND TITAN DOTIERTEM ALUMINIUMOXYD

AL. FRUMA, D. CIOMÂRTAN, I. BRAŞOVEANU und
I. V. NICOLESCU

Institut für physikalische Chemie
Bukarest, str. Dumbrava Roşie 23

Eingegangen am 7. November, 1972

Es werden die röntgenographischen Diffraktogramme einiger mit Lithium und Titanionen dotierten Aluminiumoxyde im Vergleich zum Aluminiumoxyd besprochen. Bei dem mit Lithiumionen dotiertem Aluminiumoxyd wurde ein Aluminat vom $LiAl_5O_8$-Typ festgestellt, für den die Strukturformel $Al[Li_x\square_{0.5-x}Al_{1.5}]O_4$, in der in die rechteckigen Klammern die oktaedrischen Plätze bezeichnet wurden, vorgeschlagen. Im Fall des Titan-dotiertem Aluminiumoxyds, befindet sich das Titan fein dispergiert auf die Oberfläche. Die Größe der Aluminiumoxyd-Kristalliten, befindet sich sowohl bei dem dotierten, als auch beim reinen Aluminiumoxyd zwischen 40 – 50 Å.

1. EINLEITUNG

Die weitgehende Benützung der aktiven Aluminium oxyde (γ oder η) als Träger bei der Herstellung von industriellen Katalysatoren bedingte umfangreiche Forschungen über die Möglichkeiten der Änderung der Struktureigenschaften durch Dotierung mit Fremdionen mit einer größeren oder kleineren Wertigkeit als die des Al^{3+}. [1–9]

Derartige Strukturänderungen haben manchmal einen bedeutenden Einfluß auf die katalytischen Eigenschaften des Aluminiumoxyds. Sowohl das Verständnis dieser Erscheinungen, als auch die Bestimmung der gegenseitigen Abhängigkeit zwischen den durch Dotierung verursachten Änderungen und der Besonderheit der Oberflächenreaktionen, bedingten

Röntgendiffraktionsbestimmungen und kristallographische Untersuchungen bezüglich der Lage der Dotierungsionen in Kristallgitter des Aluminiumoxyds.

Aus diesem Grunde haben wir das vorliegende Studium unternommen, in dem wir die Ergebnisse der Untersuchung der Röntgendiffraktogramme des mit Lithium- und Titanionen, in verschiedenen Konzentrationen dotiertem Aluminiumoxyds mitteilen.

2. HERSTELLUNG DER PROBEN UND MESSTECHNIK

Die untersuchten Proben wurden folgendermaßen hergestellt : Das aus Aluminiumchlorid bei einem pH = 8,5 ergebene Aluminiumhydroxyd wurde nach waschen, filtrieren und austrocknen bei 260°, mit Titannitrat- oder Lithiumkarbonatlösung von verschiedener Konzentration impregniert. Die nach dem Austrocknen gewonnene Masse wurde während 6 Stunden bei 800° ausgeheitzt. Unter diesen Herstellungsbedingungen wurden die in Tabelle 1 aufgezählten Proben erhalten.

Tabelle 1

Die spezifische Oberfläche „S" der Aluminiumoxydproben

Nr.	Atom % im Al_2O_3		S
	Li	Ti	m^2/g
1	—	—	152
2	0,5	—	158
3	2,0	—	146
4	4,0	—	139
5	—	0,5	149
6	—	2,0	138
7	—	4,0	124

Aus Tabelle 1 ist ersichtlich, daß sowohl bei dem mit Lithium als auch bei dem mit Titan dotiertem Aluminiumoxid die spezifische Oberfläche mit dem Ansteigen der Konzentration des Dotierkomponents fällt.

Für die Untersuchung mittels der Röntgenstrahlen Diffraktion, wurden die Proben vorerst eine halbe Stunde in einer Agatkapsel gerieben. Mit Hilfe des Diffraktometers TUR-M-61 wurde dann das Beugungsspektrum der einzelnen Proben aufgenommen. Die Diffraktogramme wurden auf Grund der Cu K α Strahlung ermittelt. Die Monochromatisierung erfolgte durch einen Nickel-Filter. Es wurden folgende Arbeitsbedingungen angewendet :

- Hochspannung : 30 kV
- Anodenstrom : 16 mA
- Detektor : Zähler, Typ Geiger-Müller
- Skala : $1{,}8.10^3$ Impuls/s

3. ERGEBNISSE UND DISKUSSION

Die Ergebnisse der Berechnung der interplanären Abstände und der Bestimmung der Intensitäten für die mit Lithium und Titan dotierten Aluminiumoxydproben und für die Probe mit reinem Aluminiumoxyd, sind aus Tabelle 2 ersichtlich. Die Intensitäten der Linien wurden im Verhältnis zu ihrer Oberfläche gemessen, wobei die Linie bei 1,40 Å mit Oberfläche 100 betrachtet wurde.

Nach dem Vergleich der für unsere Proben erhaltenen Daten der Röntgenstrahlendiffraktion, mit den ASTM - Karten und mit anderen veröffentlichten Arbeiten[10] können wir behaupten, daß das untersuchte Aluminiumoxyd einer Mischstruktur von γ und μ Aluminiumoxyd entspricht, wobei die γ Form vorherrscht. Das mit Lithium dotierte Aluminiumoxyd zeigt im Beugungsspektrum auch die charakteristischen Linien des Lithiumaluminats $LiAl_5O_8$, Form I und II auf. Zu diesem Schluß gelangten wir durch die Vergleichung der Beugungshöchstwerte bei d = 2,809 Å; 1,40 Å und 1,96 – 1,99 Å. Es ist ersichtlich, daß der für die Form I und II spezifische Höhepunkt bei 2,809 Å schmal ist und mit der Vergrößerung der Lithiumkonzentration in Intensität zunimmt. Die flache Form des Höhepunkts bei d = 2,30 Å und 1,40 Å deutet auf eine geringere Gitterordnung in den betreffenden Kristallebenen, wo ein größerer Beitrag der Aluminium- und Sauerstoffatomen als der Lithiumatomen vorhanden ist.

Die mittlere Partikelgröße des Al_2O_3 wurde auf Grund Scherrers Gleichung

$$D_{hkl} = \frac{k\lambda}{\beta_{hkl} \cdot \cos \theta_{hkl}}$$

aus der Beugungslinie bei 1,40Å berechnet und betrug 40 – 50 Å.

Nach der Dotierung mit Lithium blieb die Lage, Form und Breite dieser Linie unverändert, was auf dieselbe mittlere Größe der Al_2/O_3 und $LiAl_5O_3$ Partikeln deutet.

Wir betrachten für das $LiAl_5O_8$ ein gleichartiges Kristallsystem wie für das γ Al_2O_3, und zwar kubisch Fd3m. Aus den mehr unten angegebenen Abbildungen ist ersichtlich, daß die Li^+ Ionen nur oktaedrische Plätze besetzen können, und zwar die mit a′, b′ und c′ in der Abbildung 2 bezeichneten Plätze.

Nur diese Plätze können zu einer so bedeutenden Vergrößerung der Intensität, wie die experimentell bei den Höhepunkten 2,809 (220) und 1,99 (400) beobachtete Vegrgrößerung führen. Die Tatsache daß der Höhepunkt (440) bei 1,40 Å nach der Dotierung mit Lithium nicht verändert wird, beweist daß diese Linie durch den Beitrag der Aluminiumionen aus den oktaedrischen Plätzen und der umgebenden Sauerstoffatomen gebildet wird.

Die Li^+ Ionen haben einen größeren Radius als die Al^{3+} Ionen, respektiv 0,80 Å und 0,57 Å. Die durch den Beitrag der Al^{3+} Ionen gebildeten Beugungslinien sind wegen der Vibration dieser Ionen in den von ihnen besetzten tetraedrischen und oktaedrischen Plätze sehr erweitert.

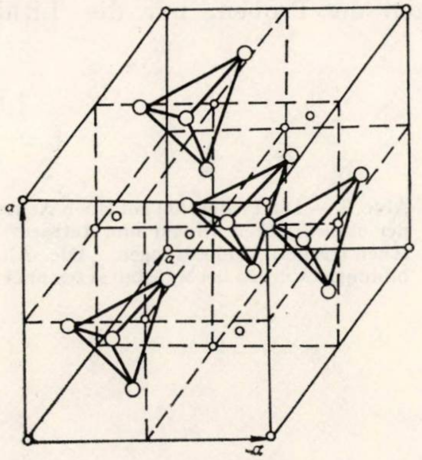

Abb. 1. — Kristallgitter des γ Al_2O_3 aus dem kubischen System Fd3m (227). Parameter a = 7,9Å. Die kleinen Kreise bedeuten tetraedrische Plätze, die größeren Kreise bedeuten oktaedrische Plätze.

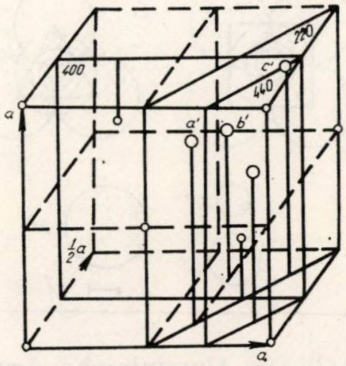

Abb. 2. — Die Hälfe der Elementarzelle des γ Al_2O_3 oder $LiAl_5O_8$. Die kleinen Kreise bedeuten tetraedrische Plätze, die größeren Kreise bedeuten oktaedrische Plätze.

Die Beugungslinien die durch den Beitrag der Li^+ erhalten wurden sind schärfer, da das Li^+ eine geringere Vibrationsmöglichkeit in der oktaedrischen Umkreisung hat, wie aus Abb. 3 ersichtlich ist.

Die Änderung der Intensitäten der Linie bei d = 2,809 Å mit der Konzentration der Li^+ Ionen weist daraufhin, daß das Lithiumaluminat freie oktaedrische Plätze besitzt, die durch Dotierung allmählich mit den Li^+Ionen von $Al[Li_x\square_{0,5-x}Al_{1,5}]O_4$ bis $Al[Li_{0,5}Al_{1,5}]O_4$, wo $0 < x < 0,5$, besetzt werden. Die Elementarzelle enthält 8 solche Strukturformeln. Diese Annahme ist in Übereinstimmung mit Brauns,[11] Jerweys[12] und Jagodzinskys[13] Arbeiten.

Im Zusammenhang zu den mit Titan dotierten Proben, machen wir folgende Bemerkungen : In den Beugungsspektren kommt nur das Bild des Aluminiumoxyds vor, wobei eine Stabilisierung der η Form erscheint. Es wurde eine mittlere Kristallitgröße von etwa 40 Å berechnet. Man bemerkt außerdem, daß die Anwesenheit des Titans bei jedwelcher Konzentration den Höhepunkt bei 1,990 Å nicht ändert. Zum Unterschied zu der Dotierung mit Lithium, befindet sich das Titan fein dispergiert auf die Oberfläche der Aluminiumoxydpartikeln.

4. SCHLUSSFOLGERUNG

Infolge der Untersuchung der Röntgenstrahlen Diffraktogramme des dotierten und reinen Aluminiumoxyds, kamen wir zur Schlußfolgerung, daß inunseren Herstellungsbedingungen der Proben, nur die Lithiumionen völlig im Aluminiumoxydgitter eingedrungen sind und das Aluminat mit der wahrscheinlichen Grenzstruktur $Al[Li_{0.5}Al_{1.5}]O_4$, in der in den geraden Klammern die oktaedrischen Plätze bezeichnet wurden, bildeten.

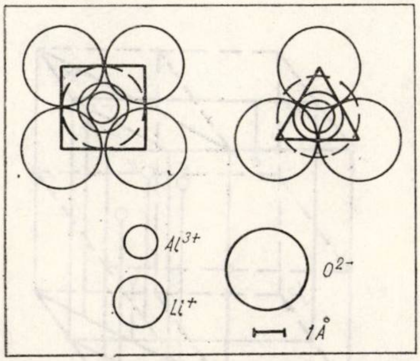

Abb. 3. — Die Projektion auf einer Achse der oktaedrischen (links) und tetraedrischen (rechts) Umkreisungen. Die Abbildungen wurden bei Maßstab gezeichnet.

In unseren Herstellungsbedingungen dringen die Ti^{4+} Ionen im Kristallgitter des Aluminiumoxyds nicht ein.

TITANIUM (IV) CHLORIDE COMPLEXES WITH COBALT (II) CHELATES OF TETRADENTATE SCHIFF BASES

N. S. BIRADAR*, V. B. MAHALE and V. H. KULKARNI
Department of Chemistry, Karnatak University, Dharwar – 3

Received November 7, 1972

The square planar cobalt (II) Schiff base complexes react with titanium (IV) chloride in chloroform medium to form complexes of 1 :1 stoichiometry. The characterization of these bimetallic complexes using magnetic and visible spectral data shows that cobalt (II) has changed its configuration from square planar to tetrahedral on reaction with $TiCl_4$. The i.r. data show that one of the two chelate rings is ruptured during the reaction. The probable structures have been suggested for these bimetallic complexes depending on the available evidences.

INTRODUCTION

The ability of some Schiff base complexes to function as neutral ligands under certain conditions has been the subject matter of a good number of publications.[1–3] They have used X-ray crystallographic information, i.e., n.m.r. and Moessbauer spectral data to characterize the complexes. Hobday and Smith[4–5] have shown that N, N′-ethylene-*bis* (salicylidene-aminato) cobalt (II) reacts with PCl_3 and $AsCl_3$ to yield cyclic derivatives and the square-planar stereochemistry of cobalt (II) changes to tetrahedral, while the complexation of $SnCl_4$ with $[M^{II}$ (Salen)] does not change the square-planar stereochemistry of M(II). Kogan and co-workers[6] have demonstrated that the reaction of titanium (IV) chloride with transition metal complexes of bidentate Schiff bases leads to the formation of substitution complexes. However, the literature records no attempts on the synthesis of titanium (IV) complexes with cobalt (II) tetradentate Schiff base complexes.

EXPERIMENTAL

The chemicals used in preparing the complexes were of reagent grade. The substituted salicylaldehydes were prepared by the Duff method.[7]

Schiff bases of ethylenediamine and propylenediamine with substituted salicylaldehydes were prepared according to the method reported elsewhere.[8]

Cobalt (II) complexes with the Schiff bases I–XII were prepared in ethanol medium[9] and dried in vacuum over fused calcium chloride.

GENERAL METHOD FOR PREPARING TITANIUM (IV) COMPLEXES

Cobalt (II) complex prepared as above was dissolved in chloroform and treated with titanium (IV) chloride in 1 :1 molar proportion, with vigorous shaking, and left to stand for several hours at room temperature with occasional shaking. The resulting precipitate of bimetal complex was filtered off and washed with chloroform and dried *in vacuo.*

ELEMENTAL ANALYSIS

In all the complexes titanium was precipitated as hydroxide, filtered, weighed as TiO_2 after ignition. Cobalt in the complexes was estimated gravimetrically as 8-hydroxy-quinolinate. Chloride was determined as AgCl and nitrogen by the Kjeldahl method. The results of the elemental analysis are shown in Table 1.

* The values in the parentheses are the calculated values.

PHYSICAL MEASUREMENTS

Infrared spectra of the complexes in nujol mulls were recorded on a Beckman IR-20 spectrophotometer in the 4000 – 250 cm^{-1} region.

Visible spectra were obtained on a Unicam S.P. 700 A recording spectrophotometer. The samples were prepared in nujol mulls. The solution spectra were taken on a Hilger

UVISPEK H-700 using 2 cm glass cells in the region 550 — 750 mμ. The samples were dissolved in DMF (A.R. grade) and diluted to the required strength.

The magnetic measurements were made at room temperature on a Gouy balance with glass tube calibrated for diamagnetism.

The molar conductance measurements of the complexes in DMF were made with an ELICO conductivity bridge having a cell of cell-constant 0.829 cm^{-1} manufactured by Electronic Industrial Instruments Co. Hyderabad.

RESULTS AND DISCUSSION

All the complexes are green in colour, amorphous and soluble in DMF. The elemental analysis (Table 1) shows that titanium (IV) chloride forms complexes of 1 :1 stoichiometry with square-planar cobalt (II) Schiff base complexes of the ligands I—XII.

The molar conductance values in DMF at the concentration 10^{-3} M show that all these complexes are non-electrolytes in DMF.

MAGNETIC PROPERTIES

The magnetic moments obtained at room temperature for the cobalt (II) complexes show μ_{eff} in the range of 2.23—2.58 BM indicating that these all possess a low-spin square-planar configuration. The bimetal complexes formed as a result of reaction of titanium (IV) chloride with cobalt (II) Schiff base complexes exhibit μ_{eff} around 4.5 BM, showing that cobalt (II) has changed its configuration from square-planar to tetrahedral as a result of complexation with titanium (IV) chloride. This finds additional support in the study of visible spectra.

VISIBLE SPECTRA

The visible spectra of the complexes have been studied with a view to establish the configuration of the bimetal complexes and to find further proof in support of the above conclusion. The square-planar cobalt (II) complexes show a band maximum around 1175 mμ. This is the characteristic band for the low-spin square-planar cobalt (II) complexes. This band is not observed in bimetal complexes of titanium (IV). Hence it may be concluded that cobalt (II) has lost its square-planar configuration in bimetal complexes.

In all the spectra, we observe an intense multicomponent band in the region 600 — 750 mμ. It is known that cobalt (II) complexes having tetrahedral configuration possess a characteristic intense multicomponent band associated with $^4A_2 \rightarrow {}^4T_1$ (P) transition in the region 600 — 800 mμ.[10,11] The multicomponent band observed in these bimetal com-

---

plexes, therefore, may be attributed to the $^4A_2 \rightarrow {}^4T_1(P)$ transition. Our observations agree well with the known tetrahedral cobalt (II) complexes.[12]

The complexes are soluble in DMT and solutions are green in colour. The visible spectra in the region 550 — 750 mμ exhibit two intense bands around 610 mμ and 675 mμ with an inflexion at 650 mμ. This multicomponent band is attributed to $^4A_2 \rightarrow {}^4T_1(P)$ transition and indicates that cobalt (II) maintains its tetrahedral stereochemistry even in the solutions. Unlike the bimetal complexes of tin (IV) which undergo change in DMF and give rise to tin (IV) Schiff base complexes,[5] these do not show any change in colour even after standing for several hours. Our observations agree well with those of Balmfield.[13]

INFRARED SPECTRA

The formation of cobalt (II) complexes with the tetradentate Schiff bases is indicated by the shift of an intense band in the region 1640 — 1620 cm^{-1} of the base, attributable to the C=N stretch, to the lower

frequency 1620—1600 cm^{-1}. The phenolic C—O vibration around 1280 cm^{-1} of the base is found in the region 1340—1310 cm^{-1} in the cobalt (II) complexes.

In the bimetallic complexes with titanium (IV) chloride, we observe an intense band around 1650 cm^{-1}, and the phenolic C—O stretch is found around 1280 cm^{-1}.

The bands around 590 and 520 cm^{-1} assignable to ν(Co—N) vibrations[14] are much altered in the bimetallic complexes.

The cobalt (II) Schiff base complexes do not show any absorption around 310 cm^{-1} attributable to ν(Co—Cl) vibration,[15] whereas the bimetallic complexes show an intense band around 310 cm^{-1} and may be attributed to ν (Co—Cl) vibration. This provides an evidence that Co—Cl bond is formed when titanium (IV) chloride has reacted with cobalt (II) complexes.

All these observations together with magnetic and electronic spectral evidences establish that the square planar coordination around cobalt (II) ion is disrupted on reaction of titanium (IV) chloride with tetradentate Schiff base cobalt (II) complexes. Similar observations have been made by Hobday and Smith.[4]

Taking into consideration all the above experimental evidences, we propose the following structure for these bimetallic complexes.

STUDIES ON COORDINATION COMPOUNDS
THIOUREA AND PHOSPHINE COMPLEXES OF Ni(II) AND Co(II)

IRSHAD A. KHAN and ANWAR H. HASHMI,

Department of Chemistry,
University of Karachi,
Karachi: — 32

Received August 2, 1972

The work described here consists of synthesis, chemical and spectral studies of some new transition metal complexes containing mixed ligands and bearing the general formula $(ML_4 \cdot 2H_2O)\ X_2$ (where M = Ni or Co ; L = thiourea or triphenyl phosphine ; X = Cl, Br or CN). The spectra of $Co\ (Thio)_5\ (NO_3)_2$ shows that at least one nitro group is forming coordination linkage with metal atom.

Coordination compounds of ligands containing more than one donor group, have been of great interest during recent years. The preferential bonding of one of the groups have been the subject of discussion in many cases.[1,2] Amino acids, amides and dithiocarbamates are some such ligands, but the compounds containing water molecules along with thiourea or triphenyl phosphine are rare.

In the present work we have tried to prepare such aqua complexes in which water molecules are coordinated to metal atom with other simple ligands and both the ligands are situated within the coordination sphere. The general formula for the complexes is proposed to be $(ML_4 \cdot 2H_2O)X_2$. The metals to be tried are nickel and cobalt, anions under consideration are chloride, bromide and cyanide. The ligands thiourea and triphenyl phosphine have been introduced.

Dipole-moment of thiourea indicates a resonance hybrid with 20 – 30% contribution of highly polar structure of thiourea.[3] Electrographic studies [4] of high temperature phase of thiourea shows the intermediate character of C—S bond between a single and double bond, whereas the value of C—M bond comes out to be 1.33 A, which proved the structure of thiourea highly polar.

RESULTS AND DISCUSSION

All the compounds described here are new except [Ni(Thio)$_6$]Br$_2$ and [Ni(ThiO)$_6$](NO$_3$)$_2$ which have been reported by other[5,6,7] workers. However, the methods of preparation of these two adopted here are original in itself and different from those already reported. Although triphenyl phosphine has been commonly used as ligand, however, the compound containing this ligand, obtained here is new and has not been reported anywhere else. Analysis and other characteristics of these compounds have been tabulated in Table 1.

Spectra observed for free thiourea in the 700 – 2000 cm^{-1} range agree well with those reported by other workers.[8,9,10] But the band observed at about 2685 cm^{-1} in this work which was not reported by Yamaguchi,[11] it is assigned to N—H bonds. This conclusion is also supported by Ollif's idea, as it will be discussed later in the case of complexes. Absorption at 1613 cm^{-1} has been assigned to NH$_2$ bonding vibrations. Yamaguchi[11] observed a splitting in this region and reported two bands at 1610 cm^{-1} and 1625 cm^{-1} corresponding to two symmetries A and B, respectively. This type of splitting, however, has not been observed in this work.

The band observed at 1983 cm^{-1} corresponds to NH$_2$ rocking modes and indicates the coincidence of A$_1$(a$_1$) and B$_1$(b$_2$) NH$_2$ rocking modes.

Calculation of Yamaguchi[11] shows that they should be distinct. Ollif,[10] however, observed a broader and weaker band at 1200 cm^{-1}, which was completely absent in the complexes.

The absorptions in 3400...3200 cm^{-1} region may conveniently be assigned to the N—H bonds, that does not seem to be shifted significantly by coordination. This region of spectrum can thus be used to determine the donor atom in a given complex. The band observed by Ollif[10] at about 3400 cm^{-1} corresponding to N—H bonds has not been observed in free thiourea or in any of the complexes. These bands are broader and this nature is most probably due to the hydrogen bonding in free thiourea.

The infrared absorption spectra of the compounds $[Ni(Thio)_4 2H_2O]X_2 (X=Cl$ or Br) proved that water is coordinated to a metal atom. Tibor Sramko[12] prepared $[Ni(Thio)_6]Br_2$ and $[Ni(Thio)_6](NO_3)_2$ by dissolving nickel nitrate, hexahydrate and lithium bromide dihydrate in acetone and adding thiourea during constant mixing, molar ratio (Ni : Thio = 1 : 9) and the latter one in acetone media, taking molar proportion (1: 6). Whereas, in the present work, these compounds are prepared by simple methods and with high yields.

The absorptions in the infrared region of new complexes are tabulated in Table 2.

Bonds observed in 3 u region at 3368, 3280, 3180 cm^{-1} for $[Ni(Thio)_4 .2H_2O]Cl_2$, 3364, 3280, 3182 cm^{-1} for $[Ni(Thio)_4.2H_2O]Br_2$ are undoubtedly assigned to the N—H stretching vibrations. These bands are broader in nature. This broader nature of these bands is assigned to considerable hydrogen bonding but not as much as in thiourea. Though Yamaguchi[11] observed the sharpening of these bands for $Ni(Thio)_2(NSC)_2$ and discussed the complete absence of hydrogen bonding. However, this sharpening is restricted only to the said compound and has not been observed for any other complex. This hydrogen bonding is similar to that described by Cavalca [13] for the compounds like $[Ni(Thio)_6]Br_2$ i.e., (Br. . .H—N). The absorptions at 3442 and 3445 cm^{-1} may conveniently be assigned to O—H stretching, indicating the presence of water in the coordination sphere. N—H bonds of the ligand thiourea gave the absorptions at 2700 and 2695 cm^{-1}. This band is not shifted appreciably on coordination which is intensive to the bonding through sulphur. Stewart [8] assigned the band as a combination of C=S and S—C—N stretching vibrations. Such a combination must be sensitive to the complex formations. That does not happen further more. These bands are not appreciably shifted from their positions. This supports the idea that these bands are due to N—H bonds.

---

[12] S. Tibor, *Chem. Zvesti*, **15**, 271 (1961).

Bands observed at 1474 and 1480 cm^{-1} (for chloride and bromide complexes, respectively) correspond to B_1 type N—C—H stretching mode, found at 1464 cm^{-1} in free thiourea. It should be sensitive to coordination through sulphur, and it increases its electron demand and thereby the double bond character of C = S decreases, whereas, the double bond character of C—N bond increases, resulting in an increase in frequency. The absorptions at 1410, 1083 and 729 cm^{-1} in free thiourea have previously been assigned to three A_1 modes, i.e. C≡S stretching, N—C—N stretching and NH_2 rocking. As it has been stated above, coordination will lead to a decrease in the C = S stretching frequency and an increase in N—C—N stretching frequency. Observed frequency will result from "hybrids" of these three modes and the effect of coordination on the frequency will depend on their relative weightings in each hybrid. . .

On coordination through sulphur, the nature of vibration is changed slightly causing a change in 1410 cm^{-1} band of thiourea (i. e. 1393 and 1390 cm^{-1}) but the presence of other absorption bands in this region makes interpretation difficult. However, the decrease has been observed. Peculiar result has been obtained in the region of 1100 cm^{-1}. Yamaguchi[11] observed that the intensity of a strong band at 1083 cm^{-1} of free thiourea is extremely weakened or disappears on complex formation. He explained that, since N—C—N stretching vibration (A_1) which increases on complex formation, cannot contribute much to the intensity in the 1100 cm^{-1} region and the major contribution which is due to C=S stretching decrease, hence the intensity of this band has decreased. We observed that this decrease is not as great as stated by Yamaguchi, but instead there is a broadening in the band, which certainly cannot be due to the relative increase or decrease of "weighting" in the "hybrid", which can produce only shift and not broadening.

For these complexes the intensity has not been decreased appreciably. The bands observed at 713 and 1717 cm^{-1} for chloride and bromide complexes correspond to 729 cm^{-1} band for free thiourea. The decrease in frequency on coordination is attributed to the decrease in double bond character of C = S bond. A similar but smaller effect of broadening the band in 1100 cm^{-1} region has been observed, which is most probably the effect of coordination.

---

[13] L. Cavalca, M. Nardelli and A. Baribenti, *Gazz. chim. Ital.*, **86**, 942 (1956).

Two new cobalt complexes $[Co(Thio)_4 2H_2O]Cl_2$ and $Co(Thio)_5(NO_3)_2$ have been prepared in alcoholic media. Except the band observed at 3459 cm^{-1} which corresponds to the coordinated water, spectra of both complexes are identical in 3 u region. The observations at 3380, 3280, 3184 and 3376, 3275, 3180 for chloride and nitrate complexes, respectively, in 3 u region are assigned to NH_2 bonds. Coordination of thiourea through nitrogen causes a splitting of these bands into groups and the decrease in their intensity.[10] None of these effects has been observed. This proves that the bonding is through sulphur, moreover, these bands are little sharper than those in thiourea which shows that hydrogen bonding is decreased up to some extent.

A weak broad band observed in the region at 2700 cm^{-1} corresponds to 2685 cm^{-1} band of thiourea assigned to N—H bonds, contrary to Yamagachi [11] who assigned it to C = S bonds. Since coordination through sulphur must bring about some changes in the double bond character of C=S bond and this must bring a shift in the position of the band, which is not the case, thus the idea that this band is due to N—H bonds seems to be more true.

In the spectra of thiourea we have assigned the band at 1613 cm^{-1} as due to NH_2 deformation. On complex formation this has been observed to split up and actually two bands have been observed in the complexes as it is obvious from Table 3, corresponding to two symmetries A_1 and B_1. This result supports Yamaguchi's analysis whereas it is quite contrary to Stewart [8] who did not observe this splitting.

Bands observed at about 1476 and 1494 cm^{-1} in these complexes correspond respectively, to 1464 cm^{-1} band of free thiourea and, due to N—C—N stretching, they are sensitive to bonding through sulphur. Absorptions at about 1400 cm^{-1} region, 1100 cm^{-1} region and 700 region have already been assigned to the bonding through sulphur and have been appreciably shifted from their positions.

Absorption at 1110 cm^{-1} for $Co(Thio)_5(NO_3)_2$ is very weak and agrees with the idea that for this complex, the chance of hydrogen bonding is least. [11] Bands observed at 825 and 1754 cm^{-1} are assigned to nitrate groups. The former one has not been shifted from its position for ionic nitrates, whereas, that at 1754 cm^{-1} has gone out of range and thus shows coordination of at least one nitrate group. Hence, the compound is better formulated as $[Co(Thio)_5(NO_3)]NO_3$. Brown [14] studied a number of nitrate esters and observed that coordinated nitrate shows a sharp peak in the range 1610—1652 cm^{-1}. Similar type of shift has been observed by Beattle[15] for nitrate compounds, when the group goes into the coordination sphere. The band observed at 717 cm^{-1} for $[Co(Thio)_4 2H_2O]Cl_2$ corresponds to chlorine and there is no considerable shift from its normal position for ionic chlorides.

Yellow coloured plates, obtained by the reaction of nickel cyanide with triphenyl phosphine, were found quite stable under nitrogen and ether vapours. Whereas, it readily decomposes in air. The formula assigned to this new compound is $[Ni(Ph_3P)_4.2H_2O](CN)_2$. Its infrared spectra are listed parallel to the spectra observed for pure triphenyl phosphine, in Table 3.

Table 3

Infrared absorptions frequencies in 650–4000 cm^{-1} region

Ph_3P	$[Ni(Ph_3P)_4.2H_2O](CN)_2$	
696 s	708 s	H–C out of plane deformation
743 vs	862 s	
998 m	1013 m	
1027 vs	1040 sh	
1071 s	1051 s	H–C in plane deformation
1090 s	1104 s	
—	1110 sh	
1180 w	1195 m	
1280 m	—	
1365 sh	1380 s	
1434 vs	—	P–C Stretching
1580 vs	—	
—	2132 vs	C–N-Stretching
3030 s	—	C=C Stretching
—	3374 s	O–H Stretching

The strong band observed at 3374 cm^{-1} may conveniently be assigned to C–H stretching, supporting the presence of water in the coordination sphere. The reported bands of triphenyl phosphine at 3030 cm^{-1} and 1580 cm^{-1} have disappeared in the complex, attributed to –CH=CH-stretching. Coordination of phosphorus to metal which may cause an electron attraction thereby producing hinderance in the delocalization of electrons, may be the reason of disappearance.

Absorption at 1434 cm^{-1} observed for triphenyl phosphine is however eliminated in the complex. This band is assigned to P–C stretching and may be due to ring vibrations. However, the 1434 cm^{-1} band is not shown in many of the spectra and there is no reason to suppose that this is not a reliable and useful correlation for P-phenyl group.[16] Dassch and Smith[17] found bands in the region 1005–995 cm^{-1} in their work attributed to P-aryl group. The band observed in this work at 1051, 1040 and 1013 cm^{-1} have quite close relation to the work mentioned above. The shifting of the absorption may be due to the coordination of phosphorus to nickel.

[17] L. W. Dassch and D. C. Smith, *Analyl. Chem.*, **23**, 853 (1951).

The absorption at 1104 cm^{-1} for the complex corresponds to 1090 cm^{-1} band of triphenyl phosphine and is assigned to an in-plane C—H deformation mode.[18] Generally, these bands for mono-substituted aromatic ring are found in the region 1050—1190 cm^{-1}. Peaks observed at 708 cm^{-1} and 862 cm^{-1} correspond to 696 and 743 cm^{-1} bands of triphenyl phosphine, and may be attributed to aromatic carbon hydrogen out of plane deformation. All these shifts in the bands indicate the coordination of triphenyl phosphine, in the complex, whereas the frequencies at 3374 and 2132 cm^{-1} support the coordination of water and ionic nature of CN group.

EXPERIMENTAL

$[Ni(Thio)_4.2H_2O]Cl_2$ — A mixture of thiourea and partly dehydrated nickel chloride (molar proportion, 4 : 1) in anhydrous methanol was refluxed for 20 minutes. The resulting green solution gave yellow crystals which are recrystallized in methanol. Yield : 58.24 %. Stable in air and unstable in water.

$[Ni(Thio)_4.2H_2O]Br_2$— The same procedure was adopted as mentioned above, having the refluxing time 45 minutes. Brownish yellow crystals were obtained from the resulting solution, which were recrystallized in methanol. Yield : 52 %. Stable in air and unstable in water.

$[Ni(Thio)_6]Br_2$— Procedure adopted was the same as described above with 30 minutes refluxing time. The resulting green solution was concentrated and 5 ml of dry ether was mixed with it and left overnight. Green crystalline material crystallized out. It was washed and recrystallized in methanol. Yield : 94 %. Stable in air and unstable in water.

$[Ni(Thio)_6](NO_3)_2$— Above mentioned procedure was adopted for the preparation. The compound obtained was crystalline. Yield : 95.3 %. Stable in air and unstable in water.

$[Co(Thio)_4 2H_2O]Cl_2$ — A mixture of thiourea and partly dehydrated cobalt chloride (molar proportion 4 : 1) in anhydrous methanol was refluxed for one hour. The resulting blue solution was concentrated and mixed with 10 ml dry ether. Next day, dark blue crystals were separated and recrystallized in methanol. Yield : 62.9 %.

$Co(Thio)_5(NO_3)_2$— Above mentioned procedure was adopted having the refluxing time of 30 minutes. Dark brown crystals were obtained from the resulting solution which were recrystallized in methanol; Yield : 58 %.

$[Ni(Ph_3P)_4.2H_2O]\ (CN)_2$— To the refluxing solution of triphenyl phosphine in anhydrous methanol, nickel cyanide (molar proportion 4 : 1) was added in small portions. The mixture was refluxed for one hour. The volume of the resulting yellow solution was reduced and mixed with dry ether and placed at —5° for 7 — 10 days in air tight flask. Yellow crystals (plates) were obtained. They were recrystallized in the same solvent. Unstable in air and water, stable in dry ether, dry methanol and dry nitrogen. Yield : 10 %.

ÜBER α-DIOXIMINKOMPLEXE DER ÜBERGANGSMETALLE. XXXVI *

NEUE DIMETHYLGLYOXIMIN-CHELATE DES KOBALTS (III) MIT α, α'-DIPYRIDYL UND *o*-PHENANTHROLIN

CSABA VÁRHELYI, ION GĂNESCU und MIRCEA PREDA

Aus der Chemischen Fakultät der Universität, Craiova,
Calea Bucureşti 165

Eingegangen am 4. Oktober 1972

Es wurde die Oxydation von Kobalt (II) Salz-Lösung in Anwesenheit von Dimethylglyoxim und heterocyclischen N-Basen untersucht und 25 Salze der $[Co(DH)_2Dipy]^+$ und $[Co(DH)_2(o\text{-phen})]^+$-Katione durch doppelte Umsetzungsreaktionen erhalten. Diese Annahme wurde auch durch U.R. spektroskopische Untersuchung behauptet.

Wie aus präparativen und IR-spektroskopischen Untersuchungen hervorgeht, gehören die meisten, bis heute erhaltene bis-Dimethylglyoximin-Chelate des Kobalts(III) vom Typ: $[Co(DH)_2AB]$ mit zwei einzähnigen Liganden (A und B) zu der *trans*-Reihe. Die zwei sehr kurzen, in diesen Verbindungen auftretenden O-H..O Wasserstoffbindungen stabilisieren die $Co(DH)_2$..-Gruppe, bzw. die *trans* geometrische Konfiguration der $[Co(DH)_2AB]$-Komplexe.[1-3] (DH= das deprotonierte Dimethylglyoxim).

Bis-dimethylglyoximin-kobalt(III)-Chelate mit cis geometrischer Konfiguration entstehen in Anwesenheit von zweizähnigen Liganden, wie aliphatischen Diamine (en, pn,), α-Aminosäuren (Alanin, Glycocoll) und zweibasische Säuren, wie Oxalsäure, Kohlensäure.[4-6]

In dieser Arbeit haben wir die Oxydation von Kobalt(II) salz Lösungen in Gegenwart von Dimethylglyoxim und der zweizähnigen heterocyclischen Diaminen: α, α'-Dipyridyl und *ortho*-Phenanthrolin untersucht.

Die ersten Bis-dimethylglyoximin-Chelate des Kobalts mit Dipyridyl und *o*-Phenanthrolin wurden von Pagglia[7] durch Wechselwirkung von $H[Co(DH)_2Br_2]$ mit den obenerwähnten Chelatbildnern erhalten.

Die Struktur der von Pagglia beschriebenen nicht wohldefinierten Substanzen: $Co(DH)(Dipy)_{2.25}.Br_2.3\ H_2O$, $CoDH_2.Br_2.o\text{-Phen}$, bzw. $CoD_2(DH)_2(o\text{-Phen})_3.4H_2O$ wurde bis heute nicht aufgeklärt.

Die obenerwähnten heterocyclischen Diamine treten leicht in die innere Koordinationssphäre der Kobalt(III)-dioximine:

$$2Co^{2+} + 4DH_2 + 2Dipy + 1/2O_2 = 2[Co(DH)_2Dipy]^+ + H_2O + 2H^+$$

$$2Co^{2+} + 4DH_2 + 2o\text{-Phen} + 1/2O_2 = 2[Co(DH)_2(o\text{-Phen})]^+ + H_2O + 2H^+$$

Die entstehenden $[Co(DH)_2Dipy]\ X$ und $[Co(DH)_2(o\text{-Phen})]\ X$ sind im allgemeinen leicht lösliche Chelate zweiter Ordnung und können aus verdünnten alkoholischen Lösungen durch doppelten Umsetzungsreaktionen ausgeschieden werden. Die $[Co(DH)_2Dipy]\ X$ und $[Co(DH)_2(o\text{-Phen})]\ X$-Salze lösen sich viel leichter im Wasser oder in verd. Alkohl, als die analogen Derivate: $[Co(DH)_2(Amin)_2]\ X$ mit aromatischen Aminen in der inneren Koordinationssphäre.

Für die doppelten Umsetzungsreaktionen haben wir insbesonders Komplexsalze mit voluminösen Komplexanionen $[Co(NH_3)_2(NO_2)_4]^-$, $[Cr(NCS)_6]^{3-}$, $[Cr(NCS)_4(Amin)_2]^-$, verwendet.

Es wurden 25 neue Komplexsalze im festen Zustand isoliert und charakterisiert. (Siehe Tabelle 1 und 2)

Es ist bemerkenswert, daß, in $[Co(DH)_2Dipy]^+$ und $[Co(DH)_2(o\text{-Phen})]^+$ Gegensatz zu den Kationen $[Co(DH)_2(Amin)_2]^+$ mit aromatischen und heterocyclischen Aminen, für die Bildung von binären Komplexsalzen vom Typ: $[Co(DH)_2\ (Amin)_2 \cdot [Co(DH)_2X_2]$ nicht geeignet sind.

$Co(DH)_2Dipy]^+$ und $[Co(DH)_2(o\text{-Phen})]^+$ sind tricyclische Chelate mit asymmetrischer Struktur, wie $[Co(en)_3]^{3+}$, $[Co(Dipy)_3]^{3+}$, $[Co(o\text{-Phen})_3]^{3+}$ und das Nichtelektrolyt $[Co(DH)_3]$[8].

Die $[Co(DH)_2Dipy]^+$, $[Co(DH)_2(o\text{-Phen})]^+$ und $[Co(DH)_3]$ sind nicht wegen sterischen Hindernissen von kurzen intramolekularen O-H..O-Wasserstoffbrückenbindungen stabilisiert.

Wie aus unseren UR-spektroskopischen Untersuchungen hervorgeht, fehlen die schwachen, für die Wasserstoffbindungen charakteristische Banden um 1680 – 1740 cm^{-1} bei den obenewähnten Komplexen. Die zwei Dimethylglyoximin-Reste besetzen also nicht den Äquatorialplan des Oktaedermodels.

In den UR-Spektren der $[Co(DH)_2\ Dipy]ClO_4$ und $[Co(DH)_2(o\text{-Phen})]\ ClO_4$ treten neben den Absorptionsbanden der Dioximligande auch jene des Dipyridyls und Phenanthrolins und deshalb haben wie auch die Spektren des $[Co(Dipy)_3]\ (ClO_4)_3$ und $[Co(o\text{-Phen})_3]\ (ClO_4)_3$ aufgenommen und verglichen.

Die komplizierten $\nu_{C\equiv N}$, $\nu_{C=N}$ Valenz- und Deformationsschwingungen und Skelettschwingungen des Dipy und *o*-Phen erschweren die Auswertung der UR-Spektren der obenerwähnten gemischen Chelaten. [9–11]

Die wichtigsten, identifizierten Ur-Schwingungsfrequenzen der untersuchten Chelate sind in der Tabelle 3 zusammengestellt.

Für die koordinierten Dimethylglyoximligande charakteristische $\nu_{C=N}$ und ν_{N-O} Banden liegen in diesen Fällen um 1530 cm^{-1} (s.), 1240 (m) und 1100 cm^{-1} (s.) von den Dipy und *o*-Phen-Frequenzen stark beeinflußt. Die ν_{Co-N} Frequenzen erschienen, wie im Falle der klassischen Kobalt (III)-aminen, bei 500—510 cm^{-1} (s.).

EXPERIMENTELLER TEIL

$[Co(DH)_2Dipy]$-acetat und $[Co(DH)_2$(o-Phen)]-acetat-Lösungen

23,2 g Dimethylglyoxim (0,2 Mol) werden in 1 l heißem Äthanol mit 23 g Dipyridyl, bzw. 30 g *o*-Phenanthrolin aufgelöst und mit 25 g $Co(CH_3\text{-}COO)_2 \cdot 4H_2O$ in 150 ml Wasser behandelt. Die Mischung der warmen Lösungen wird mit einen kräftigen Luftstrom 3 – 4 Stunden oxydiert, mit Wasser auf 1 l aufgefüllt, filtriert und zur doppelten Umsetzungsreaktionen verwendet.

Je 50 ml aus diesen Stammlösungen enthalten annähernd 5 mMol $[Co(DH)_2Dipy]$-acetat, bzw. $[Co(DH)_2$(*o*-Phen)]-acetat.

Für die doppelte Umsetzungsreaktionen wurden 20% $HClO_4$, 20% KI, 20% KCNS, 20% KCNSe, 2% $NH_4[Co(NH_3)_2(NO_2)_4]$ und 2 – 3%-ige Reineckesalzanaloga in Äthanol, bzw. in Dimethylformamid. verwendet.

Die erhaltenen Niederschläge wurden nach 10 – 15 Minuten Stehenlassen abgesaugt, mit Wasser, bzw. mit verd. Alkohol gewaschen und an der Luft getrocknet.

Chemische Analysen: Der Kobaltgehalt der Proben wurde komplexometrisch unter Verwendung von Murexid als Indicator in Acetatpufferlösung bestimmt. Die organischen Bestandteile der Komplexe wurden vorher durch Kochen mit konz. Schwefelsäure und krist. KNO_3 zerstört Der Stickstoffgehalt der Proben wurde gasvolumetrisch bestimmt.

In chromhaltigen Proben wurde die Gesamtmenge : $CO_3O_4 + Cr_2O_3$ gravimetrisch gemessen. Der Thiocyangehalt wurde gravimetrisch als $BaSO_4$ gravimetrisch gemessen.

Die Ultrarotspektra der obenerwähnten Verbindungen wurden mit einem UR 10 Spektrophotometer (Carl Zeiss, Jena) in KBr-Presslingen untersucht.

Revue Roumaine de Chimie, 18, 5, 829–840 (1973)

CONTRIBUTIONS TO THE STUDY OF LANTHANIDES WITH BIGUANIDE DERIVATIVES. VI[1]

HALOGENO- AND PSEUDOHALOGENO-COMPOUNDS OF LANTHANIDES

ILEANA ALBESCU

Center of Physical Chemistry
str. Dumbrava Roșie 23, Bucharest
Romania

Received October 30, 1972

The present paper continues the study of the vibration spectra and of the thermograms of lanthanides compounds with paludrine. HCl and paludrine. HSCN, compounds whose synthesis has been presented in a previous note. The interpretation of the chemical and physico-chemical results led us to elucidate the structure of the new combinations and to formulate them as acido-complexes.

In a previous paper[1] we presented the syntheses of some new lanthanides compounds with paludrine. HCl and pald. HSCN*, compounds of the general type:

(pald.HCl).$LnCl_3$	Ln = Nd, Sm, Eu, Gd, Dy, Ho, Yb
$(pald.HCl)_2.LnCl_3$	Ln = Nd, Sm, Eu, Yb
$(pald.HCl)_3.LnCl_3$	Ln = Nd, Sm, Eu, Gd, Dy, Ho
$(pald.HCl)_4.LnCl_3$	Ln = Sm
$(pald.HCl)_5.LnCl_3$	Ln = Gd
(pald.HCl).$3LnCl_3$	Ln = Dy, Ho
(pald.HSCN).$Ln(SCN)_3$	Ln = Nd, Sm, Tb
$(pald.HSCN)_3.Ln(SCN)_3$	Ln = Nd, Sm, Tb

In order to establish the bonding type, the absorption spectra in UV and visible were analysed. The covalency parameter δ_m assumes higher values in the new compounds than in the corresponding aquo ions. Great intensity differences have resulted from the comparison between the intensities of the absorption bands in the complexes and in the corresponding aquoions; the differences are noticed especially with those compounds for which the δ_m parameter assumes high values too.

---

* paludrine will be abridged to pald.

[1] I. Albescu, *Rev. Roumaine Chim.*, (under press).

The fact proves once more the coordination and therefore a relative covalency degree of the new synthetized compounds.

In order to establish the chemical structure of the new compounds synthetized with pald. HCl and pald. HSCN, the vibration spectra in the domain 3800 — 220 cm^{-1} have been studied. The results are presented in Table 1 and Figs. 1 — 2.

For the other compounds the IR bands (in cm^{-1}) are summarized as follows :

$pald.HCl.GdCl_3$: 3400 (v. broad) ; 2980 (m) ; 2940(w) ; 1660(v.w) ; 1550(w) ; 1510(s) ; 1480 (m) ; 1430 (v.s) ; 1390 (s) ; 1300 (s) ; 1265 (v.s) ; 1190 (vs) ; 1135 (s) ; 1100 (v.s) ; 1020 (v.s) ; 980 (v.w) ; 850 (w) ; 835 (v.s) ; 730 (s).

$(pald.HCl)_3GdCl_3$: 3300(v. broad) ; 2980 (v.w) ; 2935 (s) ; 2875 (s) ; 1600(v.w) ; 1550(w); 1510 (s) ; 1480 (m) ; 1435 (s) ; 1390 (m) ; 1300 (m) ; 1265 (s) ; 1185 (s) ; 1100 (v.s) ; 1020 (s) ; 835 (v.s) ; 730 (m).

$(pald.\ HCl)_5GdCl_3$: 3400—3200 (v. broad) ; 2985 (m) ; 1670—1620 (broad) ; 1565 (v.w) ; 1550 (w) ; 1510 (m) ; 1430(m); 1390 (w) ; 1300(w) ; 1265 (s) ; 1185 (v.s) ; 1140 (w) ; 1100 (s) ; 1020 (s) ; 835 (v.s) ; 730 (m).

$(pald.HCl.DyCl_3$: 3316 (m) ; 3208 (w) ; 3016 (w) ; 1643 (s) ; 1595 (m) ; 1536 (v.s) 1500 (v.s) ; 1465 (v.w) ; 1411 (s) ; 1383 (s) ; 1289 (m) ; 1250 (s) ; 1180 (s) ; 1132 (w) ; 1091 (s) ; 1011 (s) ; 844 (m) ; 827 (v.s) ; 722 (s).

pounds with lanthanides, [2-4] in the case of the combinations with pald. HCl and pald.HSCN the spectra ligand-compounds are very much similar, especially in the domain 3800 – 600 cm^{-1}.

Slight differences, in the sense of some shifts (730 cm^{-1}, 1260 cm^{-1}, 1380 cm^{-1}), disappearances (2990 – 1890 cm^{-1}, 1629 cm^{-1}, 1465 cm^{-1}, 980 cm^{-1}, 850 cm^{-1}) and intensifications of some bands (1411 cm^{-1}, 1550 cm^{-1}, 730 cm^{-1}) can be noticed; generally no regularity is remarked when going from an element to another of the same series of compounds.

For the compounds of the same element the more increases the quantity of ligand the wider some bands become till they completely disappear, great changes taking place at the frequencies 740 cm^{-1} and 833 cm^{-1}.

In the domain 600 – 220 cm^{-1}, pald.HCl presents bands at 243 cm^{-1}, 264 cm^{-1}, 353 cm^{-1}, 397 cm^{-1}, 422 cm^{-1}, 490 cm^{-1} and 497 cm^{-1} as well as at 532 cm^{-1}; pald.HSCN has marked bands at the frequencies : 240 cm^{-1}, 251 cm^{-1}, 321 cm^{-1}, 336 – 350 cm^{-1}, 485 cm^{-1} and 500 cm^{-1}.

Differences between the ligands spectrum and that of the compounds appear in this domain, too; in the series of the combinations with pald. HCl there are obvious changes around the frequencies 480 – 580 cm^{-1}, the bands which are in pald.HCl at 490 cm^{-1}, 497 cm^{-1} and 532 cm^{-1} appear in the compounds merged into a single band at 490 cm^{-1} which gradually widens and sometimes are shifted towards higher frequencies, when the quantity of ligand increases. The observation is valid in the region 240 – 260 cm^{-1} too : the characteristic frequencies 243, 249, 264 cm^{-1} in pald. HCl appear in the compound merged into one band, wide enough at 240 – 250 cm^{-1}; generally the greater the volume of the cation the stronger is the deformation.

The combinations with pald.HSCN mark in these regions differences between the ligand spectrum and that of the compounds, too. The characteristic bands in pald.HSCN at 485 cm^{-1} and 500 cm^{-1} appear as a single band, wide enough, at 490 cm^{-1} and those at 240 cm^{-1} and 251 cm^{-1} almost disappear, when the mass of ligand is augmented.

Because the lanthanide halides have in this region characteristic bands at almost the same values with those of the ligand it is difficult to appreciate whether the Ln-X or Ln-N bond is influenced.

From the analysis of the absorption spectra in UV and visible and of the IR spectra we shall try to hypothetically appreciate the structure of the new lanthanides combinations with pald.HCl and pald.HSCN.

As mentioned in a previous paper [4] using the data reported in the literature, [5] one showed that the band at 233 cm^{-1} in UV, which is obvious in pald.HCl, is characteristic of the conjugated system $=N-C=N-$; this band can be found in all the compounds with the above mentioned ligand, sometimes is shifted towards lower frequencies [1]; this means that the system of double conjugated bonds did not disappear but only a perturbation of the system of electrons π has occurred in the newly formed compound.

[5] R. C. Hirt and R. G. Schmidt, *Spectrochim. Acta*, **12**, 127 (1958).

As in the case of the compounds with paludrine, if we consider the ligand :

$$Cl-C_6H_4-NH-C(=NH)-NH-C(=NH)-NH-C_3H_7.HCl$$

the appearance of the system of double conjugated bonds may be explained when admitting the ligand is of the form of a quaternary salt :

$$Cl-C_6H_4-\underset{H}{\overset{\oplus}{N}}=C(NH_2)-N=C(NH_2)-NH-C_3H_7$$

or :

$$Cl-C_6H_4-NH-C(=NH)-N=C(NH_2)-\overset{\oplus}{N}H_2-C_3H_7$$

which should appear on N_1 close to *p*-Cl-phenyl, also affecting the bands at 710, 750, 831 cm^{-1}, characteristic of the *p*-Cl-phenyl, but also of the N_5 close to the isopropyl group, the affected band in this case being around the frequencies at 820 cm^{-1} and 750 cm^{-1}.

Because the IR spectra of the compounds are similar in the range 3800 – 600 cm^{-1} with that of pald.HCl, with marked changes especially at the characteristic vibrations of *p*-Cl-phenyl group (the same bands are maintained as in the free ligand slightly shifted in their frequencies), the cation formation appears more probably on the nitrogen atom (N_1) close to the above mentioned radical.

The fact led us to assume that the halogeno- and pseudohalogeno-complexes of lanthanides with pald.HCl and pald.HSCN could be considered as paludronium salts which behave as monoprotonated biguanide derivatives, of the type :

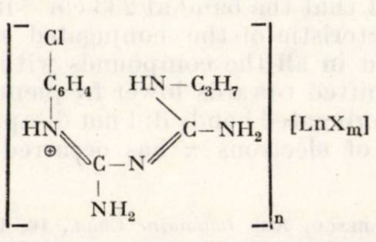
$$[\text{Hpald}]_n\,[\text{LnX}_m]$$

$$\text{Ln} = \text{Nd}-\text{Yb}\,; \qquad X=Cl^-,\ SCN^-$$

$$n = 1-5\,;\ m = 4-8 \quad (X=Cl^-)$$

$$n = 1\,;3 \quad m = 4\,;6 \quad (X=SCN^-)$$

That is to say :



Unlike the lanthanides compounds with paludrine, whose structure has been explained by a system of double conjugated bonds which appear during an internal mechanism of a limit structure created in special conditions, the compounds of acido-complex type are formed admitting a quaternary salt with the same system of double bonds but differently placed in the ligand molecule.

The formulas:

$$[\mathrm{Hpald}]_3[\mathrm{LnX}_6];\quad [\mathrm{Hpald}]_2[\mathrm{LnX}_5];\quad [\mathrm{Hpald}][\mathrm{LnX}_4]$$

are suggested, that is to say the coordination numbers 6, 5, 4, the latter compound being the most stable.

For the compounds with a high content of pald.HCl, ex. $[\mathrm{Hpald}]_4[\mathrm{SmCl}_7]$ and $[\mathrm{Hpald}]_5[\mathrm{GdCl}_8]$ the coordination numbers 7 and 8 are admitted, which is possible for the lanthanides but the compounds are less stable.

In our paper dealing with the study in aqueous solution and through the refractometrical method [6-10] of some systems of the type:

$$\mathrm{MX-LnX_3}\qquad \begin{array}{l} \mathrm{M = Na, K, Rb, Cs} \\ \mathrm{X = Cl, Br} \\ \mathrm{Ln = Ce-Yb} \end{array}$$

we proved the existence of the $[\mathrm{LnX}_n]^{n-3}$ ion regarding the possibility of formation of lanthanides combinations of acido-complex type and of a superior order. The conclusions of these researches have been greatly in agreement with those derived from the works [11-12] about meltings.

At Dy and Ho, compounds of general form $\mathrm{KLn_3Cl_{10}}$ have been noticed in solution; they correspond to those mentioned in literature, in meltings at the same elements.

It is interesting that in the series of compounds synthetized with pald HCl, combinations with a high content of $\mathrm{LnCl_3}$ and of the form: pald $\mathrm{H.Dy_3Cl_{10}}$ and pald $\mathrm{H.HO_3Cl_{10}}$ have been found at Dy and Ho too; they are similar with those studied in solutions and meltings but they have a different cation.

These combinations have the formula:

$$[\mathrm{Hpald}][\mathrm{LnCl_4}].2\mathrm{LnCl_3}\qquad \mathrm{Ln = Dy, Ho}$$

and

$$\mathrm{K[LnCl_4].2LnCl_3}\qquad \mathrm{Ln = Dy, Ho,\ respectively}$$

Their existence can be explained by the fact that the lanthanide ionic radius has reached the borderline of the possibility to form compounds with high content of $\mathrm{LnCl_3}$ by the addition of two molecules of $\mathrm{LnCl_3}$ to the most stable compound $[\mathrm{Hpald}][\mathrm{LnCl_4}]$ or $\mathrm{K[LnCl_4]}$.

We also observed that the combinations rich in pald.HCl are obtained in all the elements up to Gd; this tendency increases in the elements after Sm, that is to say, in Eu and Gd, and then it decreases; like that in Yb only compounds 1 : 1 and 1 : 2 are obtained.

In conclusion, through a chemical synthesis using biguanide derivatives as ligand, the $[LnX_n]^{n-3}$ becomes stable leading to the obtention of solid crystalline combinations.

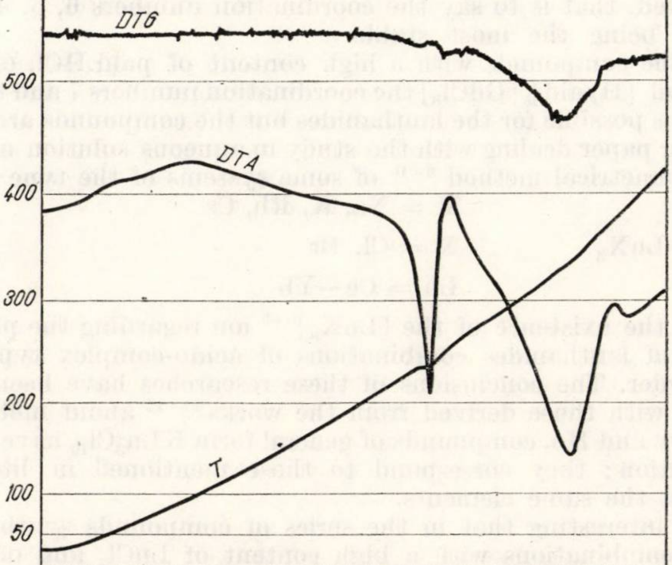

Fig. 3. — Thermal decomposition of pald.HCl.

When the new compounds were studied it obviously appeared a perfect parallelism between them and the same type of combinations studied through other methods and with different cations.

The thermal and thermodifferential analyses have been carried out by studying physico-chemically these compounds. Only the data for the combination $[Hpald]_3$ $[HoCl_6]$ are discussed because for the other compounds the results can be generalized.

The substance begins to decompose at 160° with the elimination of the ligand, operation highly marked by three steps and equivalent to the losing of 76% of weight against 76.2% theoretically calculated.

It is difficult to establish the intermediate products which could appear during the elimination of the ligand, because the processes overlap.

At about 540° $HoCl_3$ is obtained corresponding to a 23% quantity; through heating later on the anhydrous chloride passes into HoOCl, corresponding to a 18.3% quantity. Finally the latter decomposes with the appearance of Ho_2O_3, the process being marked by the last step at 700° corresponding to a 16% quantity as compared to 16.5% theoretically calculated.

The thermodifferential analysis clearly underlines the decomposition processes of the ligand and of the compound (Figs. 3 and 5).

The beginning of the decomposition process of the ligand is noticed at 150° — 160° to which an endothermal effect corresponds with the maximum at 240°. A second endothermal process of smaller intensity follows at 280° and it is hidden by the third endothermal process represented by a peak with a maximum at 340°.

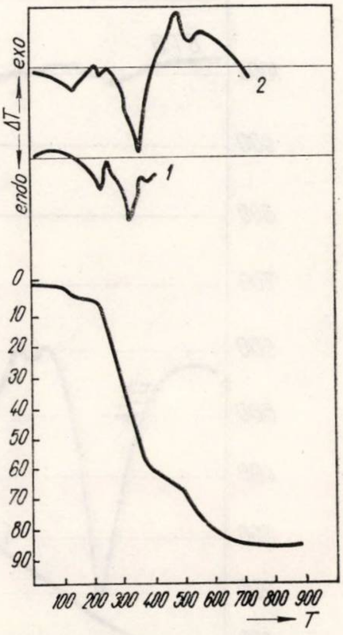

Fig. 4. — Thermal decomposition of the ligand and of the $(pald.HCl)_3HoCl_3$.

For the compound a first decomposition with the maximal speed at 150° is noticed; the process may correspond to the elimination of the absorbed water. The decomposition of the compound with the elimination of the ligand in three definite stages occurs at 225° and is represented by an endothermal process with the maximal speed at 240°, too; like in the free ligand, but the effect is smaller. The second process of decomposition of the ligand has the highest speed at 290° compared to 280° in the free ligand; the second process is also of a reduced intensity and it is hidden by the last endothermal process with a peak at 360° in comparison with 340° in the free ligand.

The two exothermal processes, the former placed within 400°—500° with a maximum at 490°, probably due to the elimination of the last residuum produced by the ligand decomposition, and the latter which begins at 540° when $HoCl_3$ occurred with a maximal speed corresponding to a peak at 570°.

If the DTA curve for pald.HCl is compared with the DTA curve of the compound, the similarity in the sense of the existence of both endothermal processes with very close maxima is also observed.

We find once more the conclusions in concordance with those found in spectral studies.

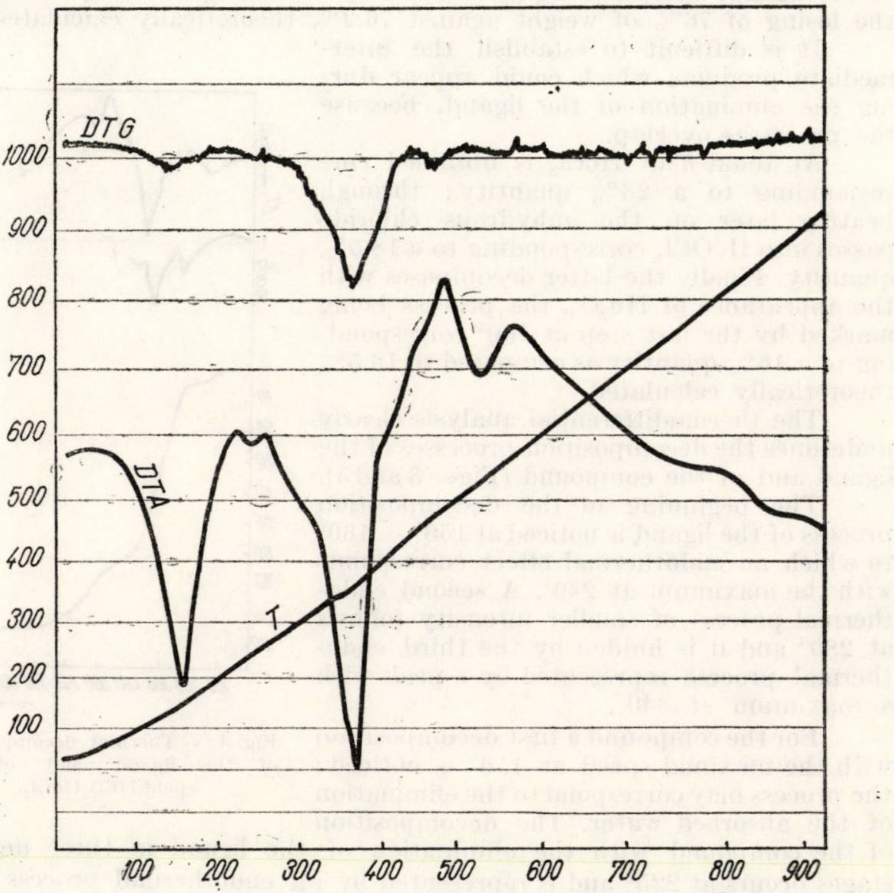

Fig. 5. — DTA for $(pald.HCl)_3HoCl_3$.

The ligand maintains its structure in the newly formed compounds with rare earth ions, hence the analogy between the spectra and the DTA curves of the compounds and those of the free ligand.

The fact that the DTA curve for pald.HCl-compounds is different from the DTA curve of the paludrine complexes and of the paludrine itself shows that the newly formed compounds have different structures than with those of the compounds reported in our previous papers.

Revue Roumaine de Chimie. **18**, *5*, 841–854 (1973)

CHEMICAL GRAPHS. XVI[1]
INTRAMOLECULAR ISOMERIZATIONS OF OCTAHEDRAL COMPLEXES WITH SIX DIFFERENT LIGANDS*

A. T. BALABAN

Institute of Atomic Physics, P.O.B. 35, Bucharest, Romania

Received December 13, 1972

Intramolecular isomerizations of octahedral complexes *via* digonal, trigonal or rhombic twists are tetra-, tri- or diligostatic processes, whose topology can be represented by regular graphs. A 15-vertex graph of degree six and a 30-vertex graph of degree twelve are presented for processes *via* digonal twists, and a 30-vertex graph of degree eight is shown for the other processes, displaying Hamiltonian circuits. The symmetry of the graph can be used for achieving a self-consistent notation of the isomers.

INTRODUCTION

Six-coordinate complexes ML_6 with octahedral geometry can give rise to $6!/24 = 30$ isomers when the six ligands L are different, i.e. to 15 pairs of enantiomers.[2] They may become interconverted through non-bond rupture mechanisms in several ways, as presented systematically by Gielen[3]; (i) Bailar trigonal twist[4]; (ii) Ray-Dutt rhombic twist,[5] or Springer-Sievers process[6]; (i) and (ii) are equivalent and can be represented by a regular graph of degree eight[7]; (iii) digonal twist,[8,9] and other mechanisms.[10] We will examine more closely cases (i) or (ii), and (iii), starting with the last one.

Two ligands *cis* to one another may interchange by a ligand metathesis, while the other four ligands conserve their positions. Such a tetraligostatic process [11] (iii) is less favoured energetically than the triligostatic process (i), or than the diligostatic process (ii), but is an interesting theoretical possibility. Process (iii) has the property that each of the 30 isomers, having twelve *cis*-ligand pairs and three *trans*-ligand pairs, and totalling as required $\binom{6}{2} = 15$ pairs, leads by *cis*-ligand metathesis to 12 different isomers forming six pairs of enantiomers. Thus, every ligand metathesis results in complete loss of chirality, which will allow a significant simplification of the problem.

The notation of the 30 isomers follows previously adopted rules.[12,13] Gielen's simplification of the six-digit notation to a two-digit notation will be adopted, remarking that the two digits determine unambiguously one pair of enantiomers. Indeed, the first digit indicates the ligand *trans* to substituent 1, whereas the second digit indicates the ligand *trans* to substituent 2, unless substituent 2 is *trans* to substituent 1, when the second digit indicates the ligand *trans* to substituent 3 (therefore, ligand 1 never appears in the notation and from all arrangements of two digits out of five, i. e. out of digits 2 through 6, arrangements 23, 32, 42, 52 or 62 never appear as notations). The third pair of ligands follows by difference. The two enantiomers are distinguished in Gielen's notation by a bar, i. e. as 24 and $\overline{24}$ (in a similar case an asterisk was used earlier [14]).

It was shown by Ruch [15] that the homochirality criterion does not apply to octahedral complexes. Therefore, the assignment of any such complex to an enantiomeric series is conventional. It will be shown in this paper that the symmetry of the graphs can be used for a consistent conventional assignment.

The 30 octahedral isomers are presented with their notations in figure 1.

REQUIREMENTS FOR TOPOLOGICAL REPRESENTATIONS OF INTRAMOLECULAR ISOMERIZATIONS

The graph representing the topology of intramolecular isomerizations consists of vertices symbolizing the isomers; two isomers which can become interconverted by an allowed elementary process are adjacent, i. e. are connected by a line.

Since the process can start from any isomer, the resulting graph must be vertex-transitive. In some cases, [14] higher symmetry is attained (s-unitransitive graphs [16] or s-regular graphs[17]).

Fig. 1. — The 30 octahedral isomers (15 enantiomeric pairs) with their notations: upper line as in ref. 10; middle line as in ref. 3 and figures 4 and 5 of the present paper; lower line, proposed assignments as in fig. 9 and 10.

The following requirements for the presentation of the graph should be observed whenever possible:

a) It should be displayed with a Hamiltonian circuit because on such a circuit there are no privileged vertices.

b) When there are two enantiomeric series, enantiomers should have antipodal positions on the Hamiltonian circuit.

c) In the latter case, the resulting graph should be displayed with alternating order of isomers belonging to the two enantiomeric series.

d) The geometrical realization should have a high symmetry.

These requirements are derived from aesthetic and from symmetry considerations and aim at displaying as well as possible the intrinsic symmetry of the graph. This can be exemplified by the 20-vertex graph of intramolecular rearrangements of five-coordinate complexes,[3,14,18–23] where the combinatorial notation (labelling) of vertices gives a consistent adjacency rule.

In the present case, however, it is only a coincidence that $2\binom{6}{2} = 30$, therefore combinations of two out of six symbols cannot be used for notations. The thirty octahedral isomers arise from the relationship $\binom{5}{1}\cdot\binom{4}{2}=30$, i.e. there are five possibilities for a ligand *trans* to substituent 1, and for each of these possibilities a second *trans*-ligand pair can be formed in six ways. This situation is rationally described by Gielen's notation adopted in the present paper.

TOPOLOGICAL REPRESENTATION OF INTRAMOLECULAR ISOMERIZATIONS OF OCTAHEDRAL COMPLEXES *VIA* DIGONAL TWISTS

In the tetraligostatic process (iii) involving digonal twists, i.e. interchange of two *cis*-ligands, each isomer can be converted into six pairs of enantiomers with loss of chirality. Disregarding enantiomerism, we need therefore consider only a 15-vertex graph of degree six; in the notation of each isomer the presence or absence of a bar can be disregarded.

Inspecting the adjacency table presented in detail by Gielen,[10] and converting it into the present notation, the following adjacency rules between vertices emerge for an isomer represented by a vertex with notation AB, which is a common vertex of three 3-circuits (denoting by Y and Z two digits from the set 4, 5 and 6 which are different from B):

1. For A = 2 (therefore, B = 4, 5, or 6), the three 3-circuits are:
   AB–AY–AZ, AB–YZ–ZY, AB–3B–B3
2. For A = 3 (therefore, B = 4, 5, or 6), they are:
   AB–AY–AZ, AB–YB–ZB, AB–2B–BA

B

Fig. 2. — Graph of intramolecular rearrangements of octahedral complexes with six different ligands *via* digonal twists, disregarding enantiomerism.

3. For $A = 4$, 5 or 6 and $B = 3$, they are:
   $AB-AY-AZ$, $AB-YB-ZB$, $AB-2A-BA$
4. For A and $B = 4$, 5, or 6 (denoting by Y' and Z' two digits from the set 3, 4, 5 and 6 which are different from A and B, i. e. $Y' = 3$, and $Z' =$ a number from the set 4, 5 or 6) they are:
   $AB-AY'-AZ'$, $AB-Y'B-Z'B$, $AB-2Z'-BA$

It can be seen that the same adjacency rule applies for the first two 3-circuits, and that slight differences arise for the third one.

The resulting graph, complying with the first and third requirements (a) and (c) (the remaining two do not apply), is presented in figure 2A. It is a regular graph of degree six with 15 vertices. An isomorphic geometrical realization of the same graph is shown in figure 2B.

Fig. 3. — Same as fig. 2 but taking all enantiomers into consideration.

The complete representation involving all 30 isomers involves two such graphs, one for the series without a bar, and the second with a bar over the notation of each vertex. The two graphs are linked by lines connecting each point from one graph with six other points from the other graph, according to the above adjacency rules. Alternatively, the graph presented in fig. 3, complying with all four requirements (a)-(d), includes all 30 isomers. This graph has the same sequence of vertices as that of figure 2, but repeated twice. Since the adjacency rules do not take into account the assignment of any isomer into a particular enantiomeric series, any change of the assignment is permitted without affecting the graphs presented in figures 2 and 3.

TOPOLOGICAL REPRESENTATION OF INTRAMOLECULAR ISOMERIZATIONS OF OCTAHEDRAL COMPLEXES *VIA* TRIGONAL OR RHOMBIC TWISTS

The result of either the triligostatic process (i) involving trigonal twists, or of the diligostatic process (ii) involving rhombic twists is the same : each isomer can be converted into eight isomers.

Considering the adjacency table presented in detail by Gielen, [3] the following adjacency rules emerge (conserving the previous conventions and disregarding the presence or absence of a bar)

1) For A = 2, the four 3-circuits are : *
AB–BY–Z3, AB–BZ–Y3, AB–YB–3Z, AB–ZB–3Y
2) For A = 3, they are :
AB–BY–YA, AB–BZ–ZA, AB–YZ–2Z, AB–ZY–2Y
3) For A = 4, 5 or 6 and B = 3 they are :
AB–BY–YA, AB–BZ–ZA, AB–YZ–2Y, AB–ZY–2Z
4) For A and B = 4, 5 or 6, they are :
AB–BY′–Y′A, AB–BZ′–Z′A, AB–Y′Z′–2B, AB–Z′Y′–2A

There is, however, no regularity whatever when the bar is considered, and this is apparently due to the fact that the assignement of isomers to the two enantiomeric series denoted by the presence or absence of a bar is not self-consistent.

Conserving Gielen's notations, the 30-vertex graph complying with the first requirement (a) is presented in fig. 4. This representation has a trigonal symmetry but does not satisfy requirements (b) or (c).

To satisfy requirement (b), this graph can be rearranged as shown in fig. 5 or 6. No rearrangement, however, can fulfil requirement (c) because four points, namely 45, $\overline{45}$, 54 and $\overline{54}$, are not adjacent to at least two points of the opposite enantiomeric series.

The minimal change in Gielen's notations and adjacency table allowing also requirement (c) to become satisfied [is] the reversal of assignments for 25 and $\overline{25}$. With this reversal, the resulting graph complying with the first three requirements, (a)—(c) is presented in figure 7. Since this last graph does not reveal a high symmetry, it is likely that more than one reversal of enantiomer notations is necessary in Gielen's adjacency table.

---

* The cuboöctahedron, and the graphs presented in figures 2, 4–9 and 3, form a series of regular graphs of degrees 4, 6, 8 and 12, respectively, where 2, 3, 4 or 6 three-circuits respectively, with no common edge, meet at each vertex.

To find out which reversals end up in a highly symmetric graph fulfiling all three requirements (a)—(c), an indirect approach was employed. Starting from the observation that the adjacency rules for digonal twists are complementary to those for trigonal or rhombic twists, the complementary graph of the 15-vertex graph from fig. 2 was constructed by linking all its pairs of disconnected vertices and removing all original lines from that graph. Thus the graph from fig. 8 was obtained.* By repeating

Fig. 9. – Graph of intramolecular rearrangements of octahedral complexes with six different ligands *via* trigonal or rhombic twists. The newly proposed assignments of isomers are used (lower line of notations in fig. 1).

its sequence of vertices twice on a 30-vertex Hamiltonian circuit, the perimeter of the graph presented in fig. 9 was obtained. Starting from vertex 24 and labelling it $\overline{24}$, one adds bars alternately over the labels of the vertices. This procedure results in the reversals of assignements relatively to Gielen's original notations for the following four pairs of enantiomers: 24, 26, 35 and 53 (i. e. those with an even difference between the two digits, excepting 46 and 64), and in the following completed adjacency rules for a vertex labelled AB in isomerizations *via* trigonal or rhombic twists:

1. For A = 2, the four 3-circuits are:
$\mathrm{AB}-\overline{\mathrm{BY}}-\overline{\mathrm{Z3}}$, $\mathrm{AB}-\mathrm{BZ}-\overline{\mathrm{Y3}}$, $\mathrm{AB}-\overline{\mathrm{YB}}-\overline{\mathrm{3Z}}$, $\mathrm{AB}-\mathrm{ZB}-\overline{\mathrm{3Y}}$
2. For A = 3, they are:
$\mathrm{AB}-\mathrm{BY}-\overline{\mathrm{YA}}$, $\mathrm{AB}-\overline{\mathrm{BZ}}-\overline{\mathrm{ZA}}$, $\mathrm{AB}-\overline{\mathrm{YZ}}-\overline{\mathrm{2Z}}$, $\mathrm{AB}-\mathrm{ZY}-\overline{\mathrm{2Y}}$
3. For A = 4, 5 or 6 and B = 3, they are:
$\mathrm{AB}-\overline{\mathrm{BY}}-\mathrm{YA}$, $\mathrm{AB}-\overline{\mathrm{BZ}}-\overline{\mathrm{ZA}}$, $\mathrm{AB}-\mathrm{YZ}-\overline{\mathrm{2Y}}$, $\mathrm{AB}-\overline{\mathrm{ZY}}-\overline{\mathrm{2Z}}$
4. For A and B = 4, 5 or 6, they are:
$\mathrm{AB}-\overline{\mathrm{BY'}}-\mathrm{Y'A}$, $\mathrm{AB}-\mathrm{BZ'}-\mathrm{Z'A}$, $\mathrm{AB}-\overline{\mathrm{Y'Z'}}-\mathrm{2B}$, $\mathrm{AB}-\mathrm{Z'Y'}-\overline{\mathrm{2A}}$.

The resulting 30-vertex symmetrical graph fulfilling requirements (a) – (d) is presented in figure 9. As seen from figures 3 and 9, the thick lines can be used for converting one hamiltonian circuit into another. The graph thus obtained is identical to the starting one (automorphism).

Literature data, summarized in a recent review, [24] evidence the need of further experimental determinations for bond rupture *versus* twist mechanisms in intramolecular isomerizations of metallic complexes. In agreement with Musher and Gielen's ideas, [10] although the previous discussion mentioned possible rearrangement mechanisms, the graphs describe rearrangement modes rather than mechanisms.

One can make a general conjecture that the symmetry of the graph representing the topology of intramolecular isomerizations can be used for obtaining a consistent notation of the isomers when other criteria fail, e.g. for molecules which are not homochiral.

CHEMICAL GRAPHS. XIX[1]

INTRAMOLECULAR ISOMERIZATIONS OF TRIGONAL-BIPYRAMIDAL STRUCTURES WITH FIVE DIFFERENT LIGANDS

ALEXANDRU T. BALABAN

Institute of Atomic Physics, P. O. Box 35, Bucharest, Romania

Received December 29, 1972

In order that in the topological representation of intramolecular isomerizations presented by pentacoördinated TBP structures *via* BPR or TR mechanisms, which is a bipartite graph with 20 vertices, the two sets of vertices be assigned to isomers from the two enantiomeric series, a simple change in the notation of TBP stereoisomers currently in use is necessary. Topological representations are given all for possible modes of rearrangement of TBP structures with five different ligands.

Many pentacoördinated phosphorus compounds and organometallic complexes possess a trigonal-bipyramidal (TBP) geometry. [2] The order of the rotation group is in this case 6, so that there are $5!/6 = 20$ isomers when all five ligands are different. [3] Their intramolecular isomerization was first discussed by Berry who devised a pseudorotation mechanism (BPR), [4] and more recently by Ugi and Ramirez who advocated that a turnstile rotation (TR) mechanism could take place in some cases.[5–9] The complete set of all possible intramolecular isomerizations was considered by Musher,[10] reformulating earlier ideas of Muetterties,[11-13] Gielen, Nasielski and Brocas.[14,15] Thus, both the BPR and TR mechanisms are denoted by Musher[10] as mode $M_1(3)$, where the subscript indicates the number of ligands conserving their positions,* and the number in parentheses indicates how many isomers can be formed in one step from a given structure (i. e. the degree of the graph representing topologically the rearrangement).

Musher made a specific call for generalizing the topological representations to cover all possible rearrangement modes listed by him. This is done in the present paper.

Theoretical calculations favour the BPR mechanism in normal cases but do not rule out a TR mechanism in cases when steric factors cause two *cis*-ligands to be closely associated.[18]

Irrespective of which of these two mechanisms (which are the most favourable energetically) is actually operating, the complete chart of reactions linking the 20 isomers is the same, since both the BPR and the TR mechanisms can convert one isomer into three other ones. In a topological representation[13,15,19,20] where a chemical species (one isomer) is represented by a point (vertex) and where a chemical reaction (one-step isomerization) is represented by a line (edge), this complete chart is a 20-vertex regular graph where each vertex has degree three (i.e. a cubic or trivalent graph).

This graph is isomorphic with the Desargues-Levi graph which was used for a first chemical application in rationalizing the rearrangements of carbonium ions.[20]

The Desargues-Levi graph was shown[21] to be a particular case of regular combination graphs: for each odd integer $n \geqslant 3$, a graph with two sets of $\binom{n}{(n-1)/2)}$ vertices of degree $\frac{n+1}{2}$ is defined. Each vertex in one set is labelled with groups of $(n-1)/2$ unordered symbols out of n symbols (these symbols can be the first n natural numbers), and the two sets are distinguished by placing a bar over the notation of vertices from one set. Two vertices are adjacent if they belong to different sets and if they have no common symbol. For $n = 5$, the Desargues-Levi graph results (figure 1). It is a bipartite or bicolourable graph by the adjacency rule, and the vertex notation with barred and non-barred symbols agrees with the bipartite character of the graph. It is not possible to obtain a hamiltonian circuit with enantiomers * in antipodal positions (requirement b of the preceding paper [22]). Figure 1 presents several isomorphic

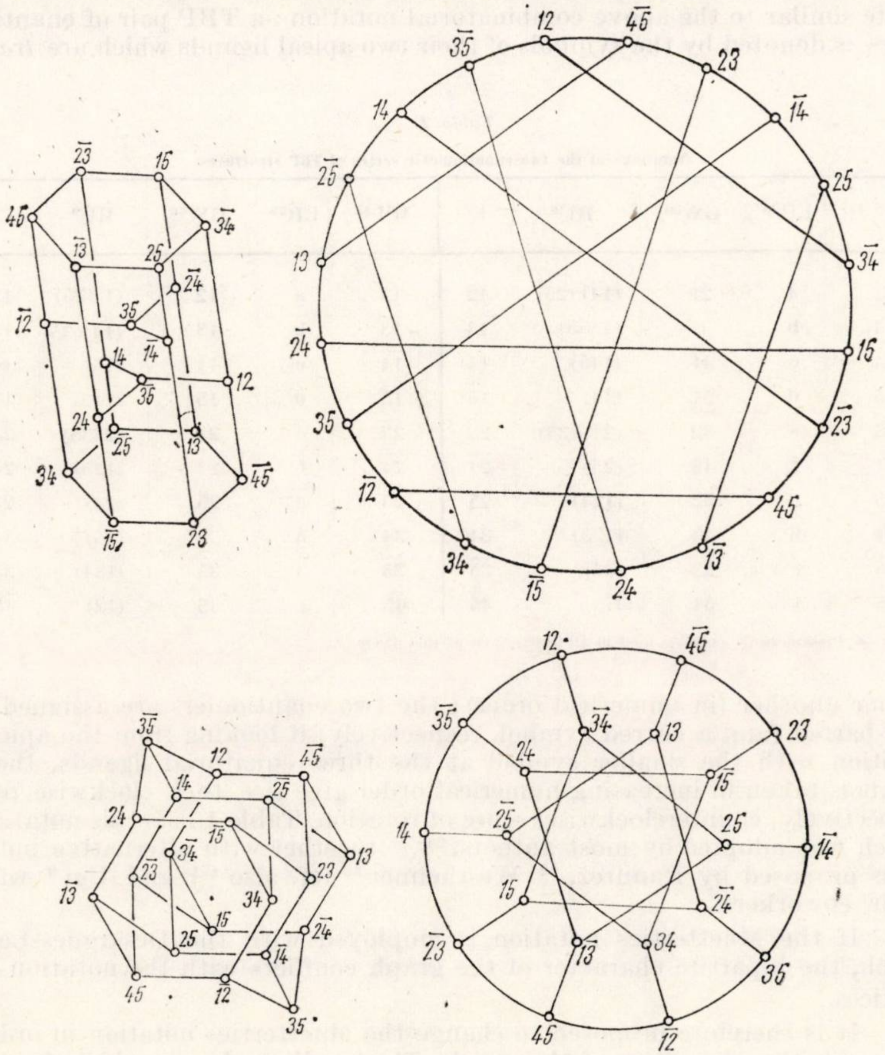

Fig. 1. — The Desargues-Levi graph in several geometric realizations with combinatorial notation of vertices.

---

* Two enantiomers will be shown to correspond to the same numerical symbol, and to differ by the presence of a bar over the symbol.

[22] A. T. Balaban, part XVI, preceding paper.

geometrical realizations of this 20-vertex graph. Its girth (smallest circuit) is six.

The notation proposed for TBP complexes by Muetterties [11,12] is quite similar to the above combinatorial notation : a TBP pair of enantiomers is denoted by the symbols of their two apical ligands which are *trans* to one another (in numerical order) ; the two enantiomers are assigned a non-barred (and a barred symbol, respectively) if looking from the apical position with the smaller symbol at the three equatorial ligands, their symbols taken in increasing numerical order give rise to a clockwise (or, respectively, counterclockwise) sense of rotation. Table 1 lists this notation which was adopted by most authors, [23–28] together with alternative notations proposed by Ramirez, [29] Westheimer [30] (cf. also [17]) and Ugi [9] with their coworkers.

[a] Present work, notation used in all illustrations of this paper.

If the Muetterties notation is employed with the Desargues-Levi graph, the bipartite character of the graph conflicts with the notation of vertices.

It is therefore proposed to change the Muetterties notation in order to match the properties of the graph. The smallest change which brings about this matching consists in *reverting the assignment into the two enantio-*

meric series whenever the difference between the two apical symbols is an even number. Unlike the case of octahedral complexes discussed previously, [22] which had many hamiltonian circuits, the present smallest change is unique. It results in the notation presented in column C (for combinatorial) of table 1. With this change, the permutational notation proposed by Ramirez and Ugi [9] becomes closely related to the new combinatorial notation, in that now every barred symbol in the combinatorial notation corresponds to one permutation of an even number of vertices in the permutational notation.

Fig. 2. — Adjacency matrix of the Desargues-Levi graph.

With the new combinatorial notation, figure 1 is at the same time a topological representation of intramolecular isomerizations in TBP complexes with five different ligands *via* BPR or TR mechanisms. The adcency matrix of the Desargues-Levi graph for the new combinatorial anotation of vertices is presented in full in figure 2 : digit 1 indicates adjacency, void stands for zero, i.e. non-adjacency. Figure 3 presents a reduced form of the previous matrix, where a minus sign indicates that two vertices from opposite sets are adjacent (e.g. 12 with $\overline{34}$; conversely, a plus sign would indicate adjacency of vertices from the same set).

If the signs in the adjacency matrix of the above graph are changed, one obtains the adjacency matrix of the topological representation of

Musher's M_5 (3) mode of rearrangement.[10] Since in the new combinatorial notation the two sets now become disjoint, the representation consists in two Peterson graphs,[21,22,31] one for each enantiomeric series: the girth is five, and the high symmetry of the Petersen graph is reflected in its identification with the 5-cage.[32]

45	—	—				—				

Fig. 3. — Reduced form of the matrix presented in figure 2.

By working out the adjacency table for Musher's $M_2(6)$ process,[10] one obtains in the new combinatorial notation another bipartite graph, which is now of degree six and whose adjacency matrix is presented in figure 4 in reduced form. One can see that the matrices from figures 3 and 4 are complementary, because minus signs and zeroes are reversed. The resulting graph is presented in figure 5. It has girth four. By following the hamiltonian circuit $12-\overline{23}-13-\overline{14}-45-\overline{15}-14-\overline{24}-23-\overline{34}-24-\overline{25}-15-\overline{12}-25-\overline{35}-34-\overline{45}-35-\overline{13}-12$ this graph is converted into a different isomorphic geometrical realization.

Fig. 6. — One of the two identical graphs representing topologically rearrangement mode $M_4(6)$ with combinatorial notation of isomers.

Musher's $M_4(6)$ mode bears the same relationship to $M_2(6)$ as $M_5(3)$ to $M_1(3)$, i.e. all signs in the reduced adjacency matrix are changed from minus to plus. Thus, instead of a bipartite 20-vertex graph, one obtains again two 10-vertex graphs for the two enantiomeric series. Now the graphs have degree six and one is presented in figure 6. It is the complement of the Petersen graph and has girth three.

For completeness, the $M_0(1)$ and $M_3(1)$ modes of rearrangement presented by Musher give rise to trivial totally disconnected graphs.

INVESTIGATIONS IN THE CYCLOBUTANE SERIES. XXXII[1]

THE ADDITION OF BROMINE TO DERIVATIVES OF *exo.exo*-TETRACYCLO[$4.4.2.0^{2.5}.0^{7.10}$]DODECA-3.11-DIENE

MARGARETA AVRAM, ILIE G. DINULESCU, FILIP CHIRALEU
and COSTIN D. NENITZESCU *

Institute of Organic Chemistry, Bucharest, Spl. Independenţei 202B

Received December 4, 1972

exo, exo-Tetracyclo-dodeca-3,11-diene derivatives were synthesized and the behaviour toward bromine was studied. The structure of the reaction products is elucidated.

It was previously observed in the case of derivatives of hydrocarbon $(CH)_{10}$ with tricyclo [$4.2.2.0^{2.5}$] decadienic skeleton **1** that the C_3-C_4 double bond of the cyclobutene ring is conveniently located for through-space interactions with the median bridge bond[2,3]. In the course of configurational and structural studies of tricyclodecadiene **1**, the ability of this kind of bonds to form stable complexes with transitional metals, of **2** type, was shown.[4]

Investigating the halogen addition, a through-space π participation of the C_9-C_{10} bond, leading to semicage systems (**3** or **4**), was demonstrated.[2]

Photochemically induced cycloaddition reactions leading to cage systems (**5**) are also well-known.[5] As a continuation of our interest concerning through-space π-p participation in the course of halogen addition, it seemed attracting to study the behaviour of some derivatives of a $(CH)_{12}$ hydrocarbon[6] with tetracyclo [$4.4.2.0^{2.5}.0^{7.10}$] dodeca-3,11-dienic skeleton (**6**), namely the cyclobutanic homolog of Nenitzescu's hydrocarbon (**7**).[7]

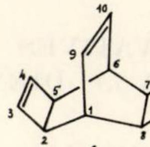
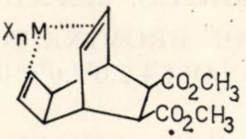
In the present paper we report the synthesis and some reactions of this system.

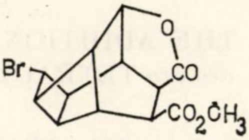
For the preparation of the tetracyclodecadiene (**6**) derivatives, the acyloine condensation was used.[8] By treating **1** with sodium, in the presence



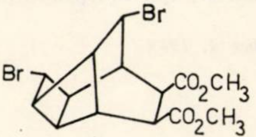
1



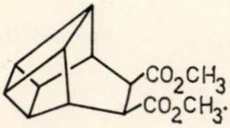
2



3

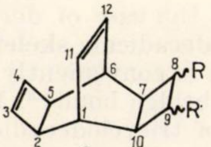


4

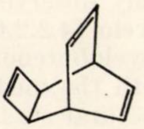


5

of trimethylchlorosilane, the bis-silyloxyderivative **8** was obtained. The hydrolysis of the latter, in acetone solution, afforded acyloin **9**. On treatment with bromine, **8** yielded diketone **10**.



6



7

The choice between the two possible configurations for acyloin, **9** and **9a**, was made on the basis of IR and NMR data and also on chemical grounds.

IR spectrum shows νCO at 1795 cm^{-1} and νOH at 3590 and 3612 cm^{-1}. On dilution the 3590 cm^{-1} band remained unchanged, indicating intramolecular hydrogen bonds. Such bonds are possible in the case of configuration **9**, where the OH group is near the double bond, which makes possible an O-H...π association. The shoulder at 3612 cm^{-1}, due to free OH, indicates a shift Δν 22 cm^{-1}. The small value of Δν, as compared with other systems,[9] could be attributed to the larger distance between the median bridge ($C_{11} - C_{12}$) and the cyclobutanolone ring. Usually, cyclic acyloins with five or six-membered rings show νOH absorptions at 3300 — — 3500 cm^{-1}, indicating intermolecular associations of OH groups.[10]

---

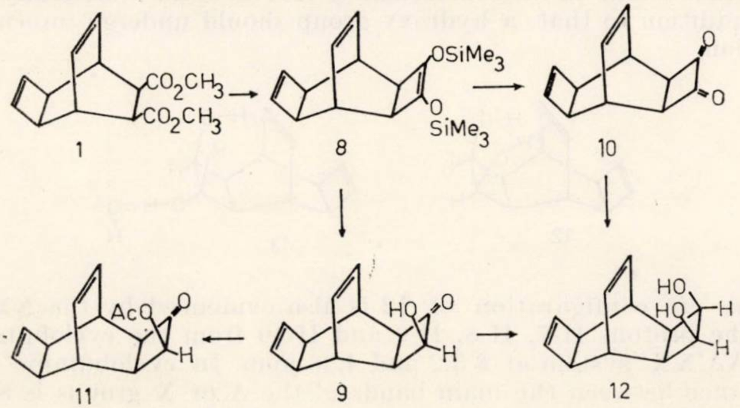
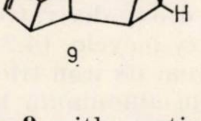
[9] M. Avram and G. D. Mateescu, "Infrared Spectroscopy. Applications in Organic Chemistry", Wiley, London, 1972, p. 252.

[10] J. C. Sheehan, R. C. O'Neil and M. A. White, *J. Amer. Chem. Soc.*, **72**, 3376 (1950); J. C. Sheehan and R. C. O'Neil, *J. Amer. Chem. Soc.*, **72**, 4614 (1950).

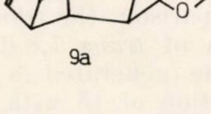
In the NMR spectrum, the proton adjacent to the OH group forms a quartet at δ 4.7 ppm with $J_{9,10} = 9$ Hz and $J_{7,9} = 4$ Hz. In cyclobutanic systems, the vicinal J_{cis} is 8.7 – 9.7 Hz and $J_{1,2\text{-}trans}$ is 6,4 – 8.2 Hz.[11]



For the $J_{1,3}$ coupling 0.5 – 2.0 Hz values are indicated. This long-range coupling can have higher values under specific steric conditions.[12] Literature [13] gives a value of 3.5 Hz for the $J_{1,3\text{-}cis}$ in a cyclobutane ring belonging to a strained and distorted bicyclic system. A 4 Hz coupling would correspond to a distorted ring, in our case due to the carbonyl group.



9



9a

By treating **9** with acetic anhydride an acetyl-derivative **11** was obtained. The NMR spectrum of **11** shows for the proton adjacent to the acetoxy group, a characteristic quartet at δ 5.6 ppm ($J_{9,10} = 9$ Hz, $J_{7,9} =$ $= 4$ Hz).

Reducing **9** with sodium borohydride, a dihydroxy-derivative **12** was obtained. The IR spectrum of **12** presents two ν OH bands at 3545 and 3615 cm^{-1}. The existence of the 3545 cm^{-1} band, unchanged by dilution, indicates an intramolecular hydrogen bond. The high value of the shift, $\Delta\nu = 70$ cm^{-1}, is in accordance with a hydrogen bond O-H. . . O, which is possible only for a *cis* configuration of the two hydroxy groups. In a *trans* derivative **13**, the hydrogen bond O-H. . .π would give a smaller shift (of the same order of magnitude as those observed for acyloin **9**); on the other hand, an intramolecular O-H. . .O bond is sterically impossible. In addition to that, a hydroxy group should undergo intermolecular association.

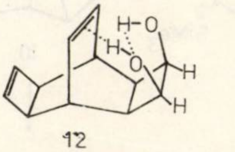
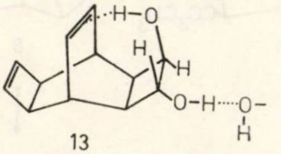
[12] S. Sternhell, *Quart. Rev.*, **23**, 236 (1969).

[13] J. W. Hanifin and G. O. Morton, *Tetrahedron Letters*, **1967**, 2307.



12



13

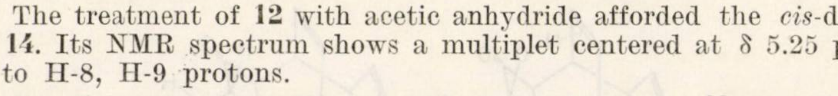
The *cis* configuration of **12** is also evidenced by the NMR spectrum. The protons H-7, H-8, H-9 and H-10 from the cyclobutanic ring form a AA'XX' system at δ 3.2 and 4.38 ppm. In cyclobutanic systems, the distance between the main bands of the A or X groups is 8–10 Hz for the *cis* and 4 – 5 Hz for the *trans* isomer. [14]

In the spectrum of **12** the distance between the main bands of the multiplet due to protons H-7, H-10 (H-8, H-9) is 8 Hz, which corresponds to *cis* orientation of the four protons.

The *cis*-dihydroxy-derivative **12** was also obtained by reducing diketone **10** with lithium aluminium hydride. In this case, the hydride ion attack is stereospecific, being directed from the unhindered part of the molecule, according to the general rule of *exo* attack in polycyclic systems. [15]

The treatment of **12** with acetic anhydride afforded the *cis*-diacetate **14**. Its NMR spectrum shows a multiplet centered at δ 5.25 ppm, due to H-8, H-9 protons.

For the comparison, the *trans*-dihydroxy-derivative **13** was synthesized, by reaction of *trans* 7,8-diacetoxy-bicyclo [4.2.0] octa-2,4-diene with cyclobutadiene (generated *in situ* from its iron-tricarbonyl complex) followed by reduction of **15** with lithium aluminium hydride.



IR spectrum of **13** presents a band due to associated OH at 3300 cm^{-1}. In the NMR spectrum, the false triplet of the olefinic protons of the bridge is broader for **13** than for **12**, which indicates [6,16] *trans* configuration of the two OH groups.

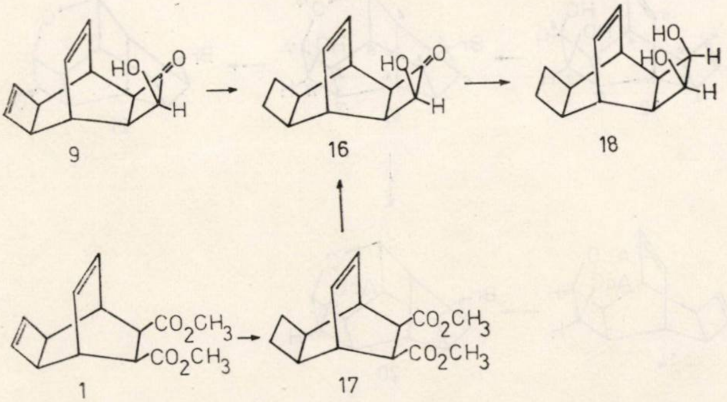
---

[14] R. Steinmetz, W. Hartmann and G. O. Schenck, *Chem. Ber.*, **92**, 3854 (1965); V. Georgian, L. Georgian and A. V. Robertson, *Tetrahedron*, **19**, 1219 (1963).

[15] E. L. Eliel, "Stereochemistry of Carbon Compounds", McGraw-Hill Book Company, Inc., New York, 1962, p. 303.

[16] J. P. Snyder and D. G. Farnum, *J. Org. Chem.*, **31**, 1699 (1966).

By catalitic hydrogenation of **9** only the double bond from the cyclobutenic ring was reduced, yielding the dihydro-derivative **16**; the double bond of the median bridge ($C_{11} - C_{12}$), sterically shielded, is unaffected under these conditions. The same dihydro compound was also obtained by acyloinic condensation of the dihydro-ester **17**.[2]



The IR spectrum of **16**, has νCO at 1795 cm^{-1} and νOH at 3600 cm^{-1}, unchanged on dilution. In the NMR spectrum, the proton H-9, adjacent to OH group, forms a quartet centered at δ 4.65 ppm ($J = 9$ Hz and $J = 4$ Hz), which is characteristic for such a system.

The treatment of **16** with sodium borohydride yielded the dihydroxy-derivative **18**.

By treating **12** with one mole of bromine in methylene chloride solution, the reaction mixture became instantly colourless and hydrobromic acid was evolved. By working up a bromohydroxy-ether $C_{12}H_{13}BrO_2$ was obtained, to which the structure **19** was attributed.

The OH group from **19**, with νOH at 3560 cm^{-1}, unchanged on dilution, is intramolecularly associated with the ethereal oxygen. In the NMR and IR spectra there are no characteristic bands of the double bonds.

With acetic anhydride, **19** underwent acetylation yielding **20**. The same acetoxy-derivative **20** was obtained by treating the diacetate **14** with one mole of bromine.

Oxidation of **19** led to ketone **21**; in the IR spectrum, of the latter, the ν CO absorption appears at 1780 cm^{-1}, in good agreement with the literature value for cyclobutanones.[17] In the NMR spectrum the proton H-12, coupled with H-9, gives a doublet centered at δ 6.07 ppm ($J = 3.25$ Hz). By irradiation of H-9, the signal of H-12 appears as singlet at δ 6.01 ppm.

---

[17] Cf. 9, p. 361.

The synthesis of ether **19** and **20** from **12**, respectively **14**, and bromine, involves the long range participation, during bromine addition, of the double bond ($C_{11}-C_{12}$) electrons and of the oxygen p electrons.

Initially, the bromine attacks the cyclobutenic double bond C_3-C_4, which is more reactive and sterically accessible.

To fill in the free orbital of the cation **22**, the π electrons of the nearby $C_{11}-C_{12}$ double bond participate preferentially, leading to the cation **23**. In cation **23** the charge is very near the oxygen of the OH or OAc group. These interactions lead to the ions **24** and **25**, respectively ; by elimination of a proton, or the acetylium ion, respectively, they give rise to the ethers **19** and **20**.

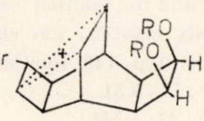
A nonclassical ion like **26** would produce the same ethers **19** and **20** through formation of a bond between C_3-C_{11}. The formation of a bond between C_3-C_{12} is sterically unfavoured.



26

Other aspects of the same subject are presently under investigation.

EXPERIMENTAL

NMR spectra were measured at 60 MHz with a Varian A60-A spectrometer. $(CH_3)_4Si$ was used as an internal standard. Chemical shifts are expressed in ppm on a δ scale. IR spectra were determined with a double beam Jena UR 20 spectrophotometer.

8,9-BIS-TRIMETHYLSILYLOXY-*exo*, *exo*-TETRACYCLO [4.4.2.0^{2,5}.0^{7,10}]DODECA-3,8,11-TRIENE (**8**)

A solution of 15 g (0.06 moles) **1** and 40 ml trimethylchlorosilane in 30 ml xylene was added dropwise over a period of 1.5 hr to a suspension of 8 g (0.35 moles) sodium in 70 ml xylene heated at 40° (in argon atmosphere). The temperature was raised at 60° in 2 hr (an exothermic reaction occured and the mixture turned violet), then the reaction mixture was heated at 80° for 6 hr. The mixture was cooled, filtered, the filtrate was evaporated in vacuo and the residue (15.5 g) distilled, yielding 12.5 g (62%) **8**, b.p. 155°/1 mm.

BICYCLO [3.3.1] NONANE
THE ACID-CATALYZED REACTIONS OF A BICYCLIC EPOXIDE

N. BĂRBULESCU, M. MORARU and D. ŞOTCĂ

Department of Organic Chemistry,
University of Bucharest, Spl. Independenţei 89,
Bucharest, Romania

Received November 29, 1972

The paper describes the synthesis and some acid-catalyzed reactions of the bicyclic epoxide **4**. The rigid conformation and the presence of a phenyl group attached to the epoxide ring are shown to be the structural factors which determine the course of all reactions under study. The stereochemistry of all new bicyclic compounds was established by chemical and spectroscopic methods.

INTRODUCTION

The cleavage of the epoxides with electrophylic reagents is a problem of current interest to organic chemists. [1] The particular course the reaction assumes depends on the nature of the epoxide, catalyst and solvent. For cyclic epoxides the structural features are generally separated into a stereoelectronic and a conformational factor, but actually, it is difficult to estimate their relative contribution. Because of their rigidity, the bicyclic epoxides are models of choice for such studies.[1–4]

We report here some results concerning the stereochemistry of the acid-catalyzed reactions of *anti*-2β, 3β-epoxy-2α-phenylbicyclo [3.3.1] nonan-9-ol (**4**); these results support and supplement those obtained by Palazzo and Baiocchi for a structurally similar epoxide.[4]

RESULTS AND DISCUSSION

The bicyclic epoxide **4** was prepared as shown in Scheme 1. The cyclisation of the diketone **1** gave the bicyclic unsaturated ketone **2**,[5] which was reduced with $LiAlH_4$ in ether to a mixture of epimeric enols

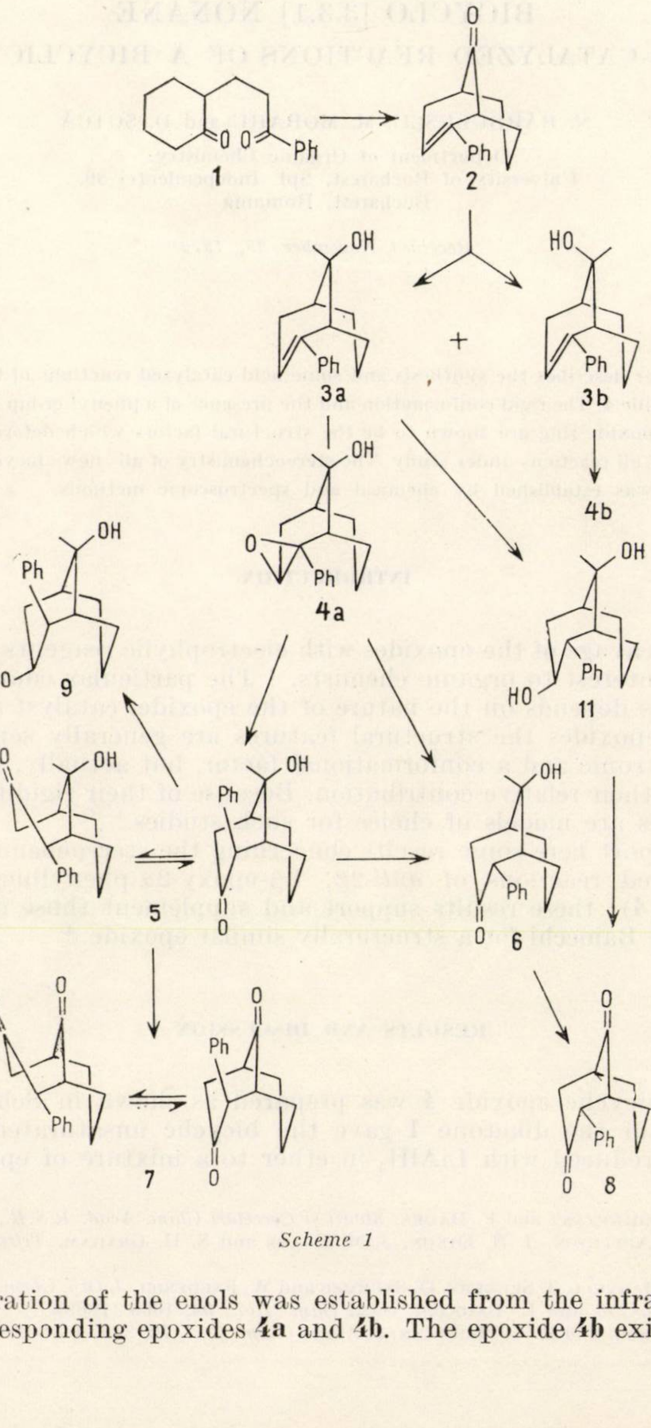
3a and **3b**. The NMR-spectra of the acetate or benzoate of the crude alcohol indicated that the major isomer **3a** represents 73 – 81%. The



Scheme 1

C-9 configuration of the enols was established from the infrared spectra of their corresponding epoxides **4a** and **4b**. The epoxide **4b** exibited intramolecular hydrogen bond between the C-9 hydroxy group and the epoxy oxygen, so it has the *sin* configuration.[6] Hence the major enol **3a** has *anti* C-9 configuration.

The course of $LiAlH_4$ reduction indicates different steric requirements to the attack from the two sides, the *anti* approach being more hindered by two axial hydrogen atoms. Several recrystallizations of the crude enol from ethanol gave a pure sample of **3a**. Epoxidation of this compound with perbenzoic acid afforded the epoxide **4a** with exo-oriented epoxy ring (Scheme 1).

The exo-attack at the double bond is a normal trend for the bicyclo [3.3.1] nonane alkenes, being encountered in the hydrogenation[5] and hydroboration of bicyclo [3.3.1] non-2-ene.

The NMR spectrum of epoxide **4a** exhibited a doublet ($J = 4$ Hz) at $\delta = 3.54$ ppm, corresponding to the oxiranic proton H-3. The doublet appearance of this proton supports the previous configurational assignment. The doublet is actually a quartet resulting from the coupling of H-3 with H-4α and a small (unresolved) coupling of about 1 Hz with H-4β. From the simplified Karplus relation $J = 5.1 \cos^2\theta$, established for steroidal epoxides,[7] a value of 27° was calculated for the dihedral angle H-3 ; H-4α. This value corresponds to a "L" half-chair conformation of the epoxide **4a**.[8]

Treatment of the epoxide **4a** with $BF_3.Et_2O$ in benzene at 20° afforded a rearranged product whose structure proved to be **5**, on the basis of chemical and spectral evidences. The infrared spectrum in KBr pellet shows peaks at 1683 cm^{-1} (carbonyl group) and 3450 cm^{-1} (OH). The NMR spectrum shows a singlet at $\delta = 3.68$ ppm due to the C-2 proton, and a triplet at $\delta = 4.30$ ppm, due to the C-9 proton. The small coupling between H-2 and the bridgehead proton H-1 (less than 1.5 Hz) is consistent with a β-configuration at C-2 (exo phenyl group).

The infrared spectrum in KBr pellet exhibits peaks at 3450 cm^{-1} (hydroxyl group) and 1683 cm^{-1} (carbonyl, but at a very low frequency). It is noteworthy that **5** shows in solution two carbonyl stretching bands at 1681 cm^{-1} and 1710 cm^{-1}. A similar splitting was recorded for 2β-phenylbicyclo [3.3.1] nonan-3-one.[4] On the other hand, the epimeric hydroxyketone **6** (see below) shows no splitting at all.

Initially, a hydrogen bond was suggested to explain this splitting, but this suggestion was rejected by a careful study of the ν(OH) region. As a matter of fact, the above explanation does not apply to 2β-phenyl bicyclo [3.3.1] nonan-3-one. The presence in solution of two different conformers could also account for such a splitting. The assumption of two conformations of comparable stability for **5** is a realistic one.

Bicyclo [3.3.1] nonane, the parent hydrocarbon, is known to occur in a double-chair conformation, but the free energy difference between this conformation and the chair-boat one is much less than in the case of cyclohexane. [9-12] ($\Delta G^0_{25} = 2.7$ kcal/mol, respectively 6.8 kcal/mol [13]). This comes mainly from a considerable repulsion between C-3 and C-7 endo protons in the double-chair conformation.

[8] M. P. Hartshorn and D. N. Kirk, *Tetrahedron*, **21**, 1547 (1965).

A carbonyl group at C-3 removes the unfavourable transannular interaction, but also decreases the diference between chair and boat by at least 1.5 kcal/mol. This value, calculated for C_s-boat form of cyclohexanone, [14,15] is equally good for the bicyclic ketone which could assume but such a boat conformation. Consequently, the double-chair and chair-boat conformations of bicyclo [3.3.1] nonan-3-one could differ by 2.5-3.5 kcal/mol and both could be populated at the normal temperature (the barrier to inversion is low for all cyclohexanones [15]). Some recent reports, on the equivalence of all protons α to the carbonyl group in bicyclo [3.3.1] nonan-3-one [16,17] support these considerations.

An exo phenyl group at C-2 introduces severe 1,3-diaxial repulsions with C-4 and C-9 protons in the double-chair conformation. The corresponding free energy gain could be assimilated with the conformational energy of phenyl in 2-phenylcyclohexanone. Calculations [18] and direct determinations of conformational energy [19] for a free rotating phenyl group give $\Delta G^0_{25} = 2 - 3.1$ kcal/mol. Thus the difference in energy between double-chair and chair-boat conformations of **5** becomes negligible and both forms are to be found in solution.

The absence of splitting for the infrared spectrum in pellet corresponds to a single fixed conformation.

Reduction of **5** with $LiAlH_4$ in ether afforded the diol **9** with an equatorial hydroxy group at C-3. The infrared spectrum of **9** exhibits the characteristic absorption bands for equatorial OH (1060 cm^{-1} and 1068 cm^{-1}). The NMR coupling constants, $J_{12} = 1.8$ Hz and $J_{23} = 6.5$ Hz, are also consistent with a β-configuration at C-3.

The diol **9** could result only by the attack of the complex hydride on the carbonyl group in the chair-boat conformation of the hydroxy-ketone **5**. For the other conformation the product would be the axial alcohol **10**. In this case the molecule would be forced in a chair-boat conformation with coupling constants $J_{12} \approx 1$ Hz and $J_{23} \approx 10$ Hz. [9]

Treatment of hydroxy-ketone **5** with HBr 47% gave the epimeric compound **6**. This was also produced by the cleavage of the epoxide **4a** with HBr 47%. The α-configuration at C-2 was confirmed by the NMR spectrum which shows a doublet ($J_{12} = 4.7$ Hz) at $\delta = 3.70$ ppm, due to the H-2 proton. The magnitude of J_{12} is normal for an axial-equatorial coupling.

Table 1

NMR-and IR-data for compounds 5–8

	Chemical shift (δppm)				J_{12}	$\nu(C=O)cm^{-1}$	
	H−1	H−2	H−4	H−9		KBr pellet	CS_2
5	—	3.70	2.55	4.30	1	1 683	1680, 1 710
6	—	3,68	2.58	4.34	4.7	1 706	1 711
7	3.08	4.01	2.80	—	0.8	1 725	1 720
8	2.73	4.03	2.88	—	5	1 723	1 724

Noteworthy is the coincidence of chemical shifts of C-2 protons in the NMR spectra of the epimeric compounds **5** and **6**. This coincidence is also consistent with a chair-boat conformation of **5**, which has the same geometry of the $C_2 - C_3$ fragment as compound **6** in the chair-chair conformation.

The hydroxy-ketones **5** and **6** were treated with Jones reagent to afford the epimeric 1,4-diketones **7** and **8**. In their NMR spectra the H-2 proton occurs as a singlet, respectively as a doublet, in agreement with the previous assigned configuration (See Table 1).

The hydroboration of the enol **3a** furnished a chemical proof of the stereochemistry of compounds **5** – **8**. When oxidized with Jones reagent, the hydroboration product **11** gave the diketone **8**. Hydroboration of the enol **3a** led to the diol **11** with a $2\alpha, 3\beta$ configuration. This assignment was supported by the NMR spectrum ($J_{12} = 3.8$ Hz and $J_{23} = 11$ Hz), the intramolecular hydrogen bond between OH and phenyl ($\Delta\nu_{OH} = 48$ cm^{-1}) and the ν(C−OH) stretching bands (1052 cm^{-1} and 1062 cm^{-1}).

The isomerisation of the epoxides to ketones by treatment with BF_3 is a well-known process.[4,20–24] The reaction involves the cleavage of the epoxy ring by the electrophilic catalyst, followed or concerted with a 1,2-hydride shift. The inversion of configuration for substituted epoxides was considered as an argument for the concerted mechanism.

Which carbon-oxigen bond is broken depends upon the electronic and conformational factors. In the case of the epoxide **4a** both are respons-

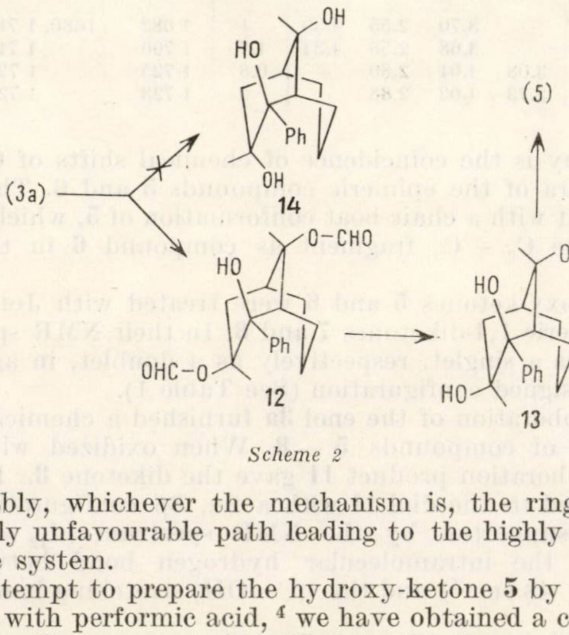
ible for the breaking of the C_2-O bond. The equatorial cleavage, accompanied by a 1,2-hydride shift, is the usual path for "L"-conformers.[8] On the other side the scission of the C_2-O bond produces the stable benzylic carbocation.

As it was pointed out, some other aryl-substituted epoxides with a fixed conformation, i.e *cis*- and *trans*-1-phenyl 4-t-butyl-cyclohexen-1, 2-oxides, give not only 1,2-hydride shift products but also ring contracted componds.[23] The absence of such ring contracted products in the reaction of **4a** is unexpected on mechanistic grounds. The concerted, 1,2-hydride shift mechanism cannot account for this result as the reaction of the alcohol **13** with BF_3 Et_2O (a process with a well established nonconcerted mechanism) affords only the hydroxy-ketone **5** (see Scheme 2).



Scheme 2

Presumably, whichever the mechanism is, the ring contraction is an energetically unfavourable path leading to the highly strained bicyclo [3.2.1] octane system.

In an attempt to prepare the hydroxy-ketone **5** by the epoxidation of the enol **3a** with performic acid,[4] we have obtained a complex mixture of formic esters (five products identified by thin layer chromatographiy). The main product (30 – 40%) is the formic diester **12**.

The IR spectrum of 12 has the characteristic peaks at 1191 cm^{-1} and 1728 cm^{-1}. The NMR spectrum exhibits two doublets (J = 1 Hz) at $\delta = 7.90$ ppm and $\delta = 8.12$ ppm, corresponding to formic esters of secondary hydroxy groups, two triplets at $\delta = 6.29$ ppm (J = 8.5 Hz) and $\delta = 5.77$ ppm (J = 2.5 Hz), due to C-3 and C-9 protons, and a singlet at $\delta = 2.74$ ppm, due to the tertiary hydroxyl. These NMR data agree with a β-configuration at C-3 (equatorial OCHO).

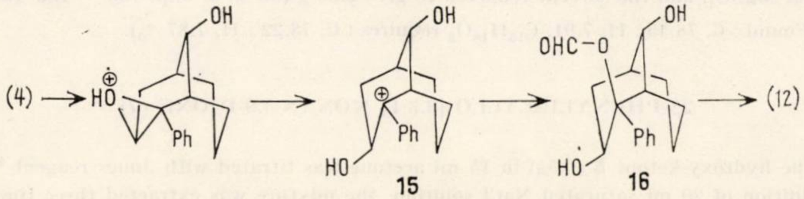
Reduction of the formic ester **12** with $LiAlH_4$ gave the triol **13** (Scheme 2), whose NMR spectrum exhibited a triplet at $\delta = 4.83$ ppm (J = 8.2 Hz), in agreement with a β-configuration at C-3.

The same triol **13** was prepared by *cis*-hydroxylation of the enol **3a** with osmium tetroxide. The well established stereochemistry of this reaction prompted us to assign the β-configuration at C-2 (axial tertiary OH).

The configuration of the formolysis products **12** is in total disagreement with the well known rule of diaxial opening of the epoxides. For the epoxide **4a** this rule would require the scission of C_3-O bond and the formation of the 2β, 3α-triol **14**.

The infringement of the rule is another consequence of the preferential formation of a stabilized benzylic carbocation.

The developing or solvent-protected carbocation would collapse with a solvent molecule from the exo-side, to yield the unstable tertiary formic ester **16**. This intermediate probably undergoes an axial-equatorial formyl shift [22] to give the normal diester **12**. (Scheme 3)



Scheme 3

EXPERIMENTAL

Infrared spectra were determined on a UR-20 spectrophotometer for solutions in CCl_4 and CS_2, or in KBr pellets.

NMR spectra were recorded on a Varian A-60 A spectrometer in CCl_4, $CDCl_3$ and DMSO-d_6 solutions, with TMS as internal standard. The hydroxy groups were assigned by exchange with D_2O. Coupling constants were measured at 250 Hz S.W.

Melting points were determined with a Boetius apparatus and are uncorrected.

2-PHENYLBICYCLO [3.3.1] NON-2-EN-9-0L (3)

To 10 g $LiAlH_4$ in 500 ml dry ether a solution of 106 g unsaturated ketone **2**,[5] in 500 ml ether was added for 2 h. The reduction was completed by heating 10 h at reflux. Excess $LiAlH_4$ was destroyed and the product worked up as usually to afford 98 g crude alcohol, b.p. 184 – 185° at 3 mm Hg.

The *anti*-alcohol **3a** was obtained by repeated recrystallization of the crude alcohol from ethanol.

2β, 3β-EPOXY-2α-PHENYLBICYCLO [3.3.1] NONAN-9-0L (4a)

To a solution of 15 g perbenzoic acid in 250 ml chloroform at 0°, were added dropwise 21.4 g **3a** in 50 ml chloroform, and the solution was kept overnight in a refrigerator. An iodometric titration gave 1.53 g excess peracid (the calculated excess).

The chloroformic solution was washed with saturated $NaHCO_3$ solution, water, then dried over anhydrous $MgSO_4$. The solvent was removed to give 21.8 g crude epoxide (95 %), m.p. 138-150°.

After recrystallization from acetone-water, m.p.154 — 155°.
(Found : C, 78.35 : H, 7.71. $C_{15}H_{18}O_2$ requires : C, 78.22 : H, 7.87 %).

2β-PHENYLBICYCLO [3.3.1] NONAN-9-OL-3-ONE (5)

A solution of 2.67 g epoxide **4a** in 300 ml dry benzene was stirred with 2 ml $BF_3.Et_2O$ for 2 minutes, then quenched with $NaHCO_3$ solution. The organic layer was washed with water, dried over $MgSO_4$, and the solvent removed to give 2.36 g (88 %) **5**, m.p. 155 — 156° (benzene)
(Found : C, 78.45 : H, 7.91. $C_{15}H_{18}O_2$ requires : C, 78.22 : H, 7.87 %).

2β-PHENYLBICYCLO [3.3.1] NONAN-3,9-DIONE (7)

The hydroxy-ketone **5** (0.5g) in 15 ml acetone was titrated with Jones reagent [25] at 0°. After addition of 20 ml saturated NaCl solution, the mixture was extracted three times with 50 ml ether, the extracts were washed with $NaHCO_3$ solution, water, dried over $MgSO_4$ anh. and the ether distilled to give 0.37 g (64 %) diketone **7**, m.p. 97—99° (from ethanol 80 %).
(Found: C, 78.75 : H, 7.11. $C_{15}H_{16}O_2$ requires : C, 78.92 : H, 7.06 %).

2α-PHENYLBICYCLO [3.3.1] NONAN-9-OL-3-ONE (6)

a) The epoxide **4a** (4.28 g) was heated at 60° in 30 ml HBr 47 % for 15 minutes. Addition of water to the clear violet solution gave 3.96 g **6** as needles, m.p. 144—145°.

b) By the same procedure compound **5** (0.5 g) gave 0.36 g **6**. The two products have the same IR spectrum and their mixed m.p. shows no depression.
(Found: C, 78.09: H, 8.01. $C_{15}H_{18}O_2$ requires: C, 78.22: H, 7.87 %).

2α-PHENYLBICYCLO [3.3.1] NONAN-3,9-DIONE (8)

a) The hydroxyketone **6** (0.22 g), treated with Jones reagent and worked up as above, produced 0.207 g oil, which was chromatographed in pentane over alumina to give 0.157 g **8**, m.p. 160—162°.

b) The oxidation of diol **11** (0.43 g) with Jones reagent as described, gave 0.39 g **8** as white crystals, m.p. 161 — 162°.
(Found : C, 78.91 : H, 7.28. $C_{15}H_{16}O_2$ requires : C, 78.92 : H, 7.06 %).

2α-PHENYLBICYCLO [3.3.1] NONAN-3β,9-DIOL (11)

A solution of 1 ml freshly distilled $BF_3.Et_2O$ in 5 ml dimethoxyethane was added dropwise, under nitrogen, to 2.14 g **3a** in 30 ml diglyme. The borane was decomposed at 40—50° with H_2O_2 30 % and NaOH 3N, the mixture was saturated with NaCl and extracted with 500 ml benzene. Evaporation of solvent left 1.95 g **11**, m.p. 178—179° (from ethyl acetate-petroleum ether).

---

[25] R. G. Curtis, I. Heilbron, E. R. H. Jones and G. F. Woods, *J. Chem. Soc.*, **1953**, 457.

(Found : C, 77.63 : H, 8.31. $C_{15}H_{20}O_2$ requires : C, 77.55 : H, 8.68 %).

2β-PHENYLBICYCLO [3.3.1] NONAN-3β, 9-DIOL (9)

The ketol **5** (0.943 g) was reduced with 0.5 g $LiAlH_4$ in 250 ml ether for 5 hr, at reflux. Excess $LiAlH_4$ was destroyed, the separated alumina washed with ether, and the combined etheric solutions were washed with water and dried. After removal of ether, the solid compound **9** (0.933 g) was obtained. M.p. 103 — 105° from AcOEt-petroleum ether.

(Found : C, 77.93 ; H, 8.33. $C_{15}H_{20}O_2$ requires : C, 77.55 : H, 8.68 %).

2α-PHENYLBICYCLO [3.3.1] NONAN-2β, 3β, 9-TRIOL (13)

a) To a stirred suspension of 10 g **3a** in 500 ml HCOOH 98 % at 50 — 60° was added H_2O_2 30 % (5 ml), stirring was continued for 1 hr to obtain a clear solution, then the mixture was poured into 300 ml ice water. The product was thoroughly extracted with chloroform, the organic layer was washed with diluted brine, water and dried over $MgSO_4$. Removal of the solvent left 11.3 g oil which was taken with a small amount of warm ethanol. The solution set aside overnight in a refrigerator separated 3 — 4 g of a product, melting at 161 — 162° (from benzene), which is the formic diester **12**.

(Found : C, 67.00 : H, 6.89. $C_{17}H_{20}O_5$ requires : C, 67.09 : H, 6.62 %).

The formic ester **12** (0.82 g) was reduced with $LiAlH_4$ (1 g) in ether to give 0.51 g **13**, m.p. 182 — 183° (from AcOEt-petroleum ether).

b) *cis*-Hydroxylation of **3a** with OsO_4.

The enol **3a** (0.84 g) in 10 ml dry ether was treated with OsO_4 (1 g) and dry pyridine (2ml) at 0°. The solution was set aside overnight, then the brown precipitate was filtered and washed with ether.

The osmic complex (2.21 g, 92 %) was treated with 3 g mannitol in 30 ml KOH 10 % to afford 0.71 g **13**, m.p. 180 — 183°.

(Found : C, 72.66 : H, 8.17. $C_{15}H_{20}O_3$ requires : C, 72.55 : H, 8.10 %).

REACTION OF 13 WITH $BF_3.ET_2O$

The triol **13** (0.15 g) in 100 ml benzene was treated with $BF_3.Et_2O$ (1ml) at room temperature for 5 minutes, then quenched with saturated $NaHCO_3$. On work-up as described we obtained an oil (97 mg), which was chromatographed on alumina to give 55 mg **5**, m. p. 154 — 155°.

We are indebted to D. Pop for performing IR-spectra and to F. Chiraleu for performing NMR-spectra.

TRIS-ÉTHERS. I

LA CONDENSATION DU BIS(CHLOROMÉTHYLE) ÉTHER AVEC LES PHÉNOXYDE, MÉTHYLE- ET DIMÉTHYLE-PHÉNOXYDES DE SODIUM

M. IOVU et G. CÎMPEANU

Faculté de Chimie, Université de Bucarest
Splaiul Independenţei, 89, Bucarest

Reçu le 11 Septembre 1972

Dans les articles antérieurs,[1–4] on a montré la possibilité de la polycondensation des dérivés dichlorométhylés aromatiques avec des phénoxydes alcalins, qui, contrairement à la réaction Ullmann, a lieu à des températures basses (moins de 65°) dans le solvant et sans catalyseur (cuivre métallique). Les phénoxydes alcalins anhydres ont été obtenus par la distillation azéotrope de l'eau. Dans les conditions similaires à celles mentionnées a aussi lieu la condensation du bis(chlorométhyle) éther avec les phénoxydes alcalins. Il résulte des tris-éthers dont la formule générale est : $Ar\text{-}O\text{-}CH_2\text{-}O\text{-}CH_2\text{-}O\text{-}Ar$ où le radical aromatique peut être substitué. Dans les tris-éthers obtenus on trouve une fonction éther aliphatique et deux fonctions mixtes aliphatiques-aromatiques, fait mis en évidence par analyse spectrale en UV et IR.

Les bons résultats obtenus dans l'étude de la condensation des phénoxydes alcalins avec des dérivés dichlorométhylés aromatique,[1–4] selon un nouveau procédé, nous ont déterminés à l'étendre aussi à la condensation du bis(chlorométhyle) éther avec les phénoxydes alcalins. Conformément au nouveau procédé les phénoxydes alcalins anhydres sont obtenus par la réaction du phénol avec l'hydroxyde alcalin en milieu d'éthanol-benzène (1 :1 en volumes) suivie par l'élimination de l'eau de réaction en distillant un mélange azéotrope eau-éthanol-benzène.

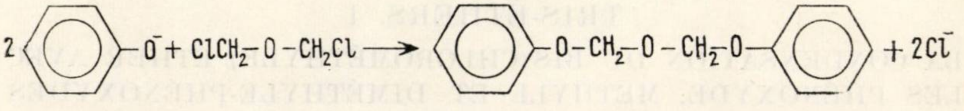
[2] M. Iovu et N. Nicolau, *Rev. Roumaine Chim.*, **16**, 1919, (1971).

[3] M. Iovu, *Rev. Roumaine Chim.*, **17**, 1261 (1972).

[4] M. Iovu, N. Miclovici et S. Creţu, *Rev. Roumaine Chim.*, **17**, 1417 (1972).

On ajoute au phénoyxde alcalin se trouvant en mélange de benzène et d'alcool qui n'a pas été distillé, le bis(chlorométhyle) éther



Il résulte le tris-éther correspondant et le chlorure de sodium qui précipitent ensemble. Le précipité est isolé des solvants contenant de petites quantités de matières premières n'ayant pas réagit et éventuellement des produits secondairs de réaction, par filtration. La chlorure de sodium est ensuite éliminé en lavant le précipité sur le filtre avec de l'eau. Le produit de réaction, séché, est cristallisé de nouveau toujours du mélange d'éthanol-benzène en proportions différentes.

Selon ce procédé on a condensé le bis(chlorométhyle) éther avec les sels de sodium du phénol, des crésols et des xylénols en obtenant dix tris-éthers qui n'ont pas été décrits jusqu'à présent dans la littérature, dont la formule générale est Ar-O-CH_2-O-CH_2-O-Ar où Ar est un phényle, un crésyle ou un xylénile. La fonction éther se trouve trois fois dans la molécule : une fois comme éther aliphatique et deux fois comme éther mixte, aromatique et aliphatique.

RÉSULTATS ET DISCUSSIONS

Sur le tableau 1 on trouve les formules des tris-éthers synthétisés, les résultats de l'analyse du carbone et de l'hydrogène, les températures de fusion, les valeurs des longueurs d'onde et les coefficients molaires d'extinction obtenus de l'analyse en UV (en cyclohexane), ainsi que les rendements.

Tous les produits sont solides, cristallins, les températures de fusion étant influencées par les positions des radicaux méthyle sur les noyaux benzéniques. Ces températures sont inférieures aux températures de fusion des bis-éthers synthétisés antérieurement[1-3] ceux-ci se faisant remarquer des tris-éthers par l'existence d'un noyau benzénique au lieu de l'atome d'oxygène médian et ayant la formule générale Ar-O-CH_2-Ar-CH_2-O-Ar.

Les rendements peuvent dépasser 90%. La différence relativement grande entre les rendements dont on obtient les différents éthers synthétisés est plutôt due à leur solubilité différente dans le milieu de réaction (alcool-benzène) d'où ils cristallisent. La concentration a été maintenue la même.

L'analyse spectrale en IR fait ressortir l'existence des bandes d'absorption caractéristiques des fonctions éther aliphatique -CH_2-O-CH_2- et mixte Ph-O-CH_2-. Les groupements méthylène appartiennent à deux fonctions éther -O-CH_2-O-CH_2-O-. Celles-ci conduisent à des spectres IR différents de ceux des bis-éthers synthétisés antérieurement.[1-4] On en trouve pour ν_{asym} C-O-C entre 1200 – 1115 cm^{-1} deux bandes intenses d'absorption, une due à la fonction éther aliphatique-aromatique (figure 1). La bande de 1160 à 1190 cm^{-1} est attribuée à la vibration des éthers mixtes.

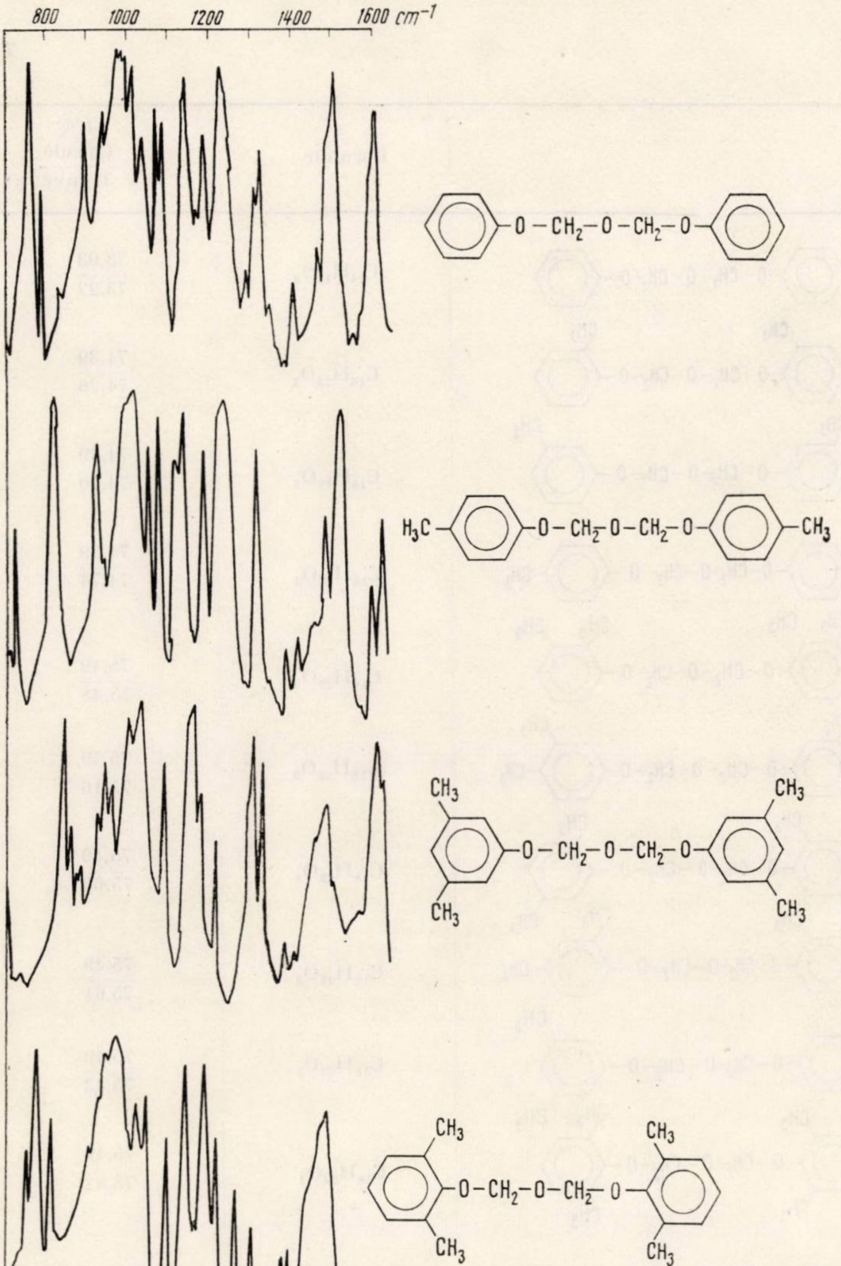


Fig. 1. — Spectres IR du bis(phenoxyméthyle) éther, bis(4-méthylphenoxyméthyl) éther, bis (3,4-diméthylphenoxyméthyl) éther et du bis (2,6-diméthylphenoxyméthyle) éther.

Tableau

TRIS-

	Formule	C % Calculé / Trouvé
	$C_{14}H_{14}O_3$	$\frac{73,03}{73,22}$
	$C_{16}H_{18}O_3$	$\frac{74,39}{74,26}$
	$C_{16}H_{18}O_3$	$\frac{74,39}{74,70}$
	$C_{16}H_{18}O_3$	$\frac{74,39}{74,74}$
	$C_{18}H_{22}O_3$	$\frac{75,49}{75,48}$
	$C_{18}H_{22}O_3$	$\frac{75,49}{75,16}$
	$C_{18}H_{22}O_3$	$\frac{75,49}{75,63}$
	$C_{18}H_{22}O_3$	$\frac{75,49}{75,61}$
	$C_{18}H_{22}O_3$	$\frac{75,49}{75,43}$
	$C_{18}H_{22}O_3$	$\frac{75,49}{75,82}$

De même, pour ν_{sym} C—O—C, il existe pour la plupart des éthers appartenant à ce groupe, deux bandes entre 940 — 920 cm^{-1}.

Les tris-éthers synthétisés, absorbent en UV dans la région de 260 à 280 mμ caractéristique des composés benzéniques. La substitution du noyau benzénique par des radicaux méthyle déplace les bandes d'absorption par rapport à la position des radicaux vers des longueurs d'ondes plus grandes (tableau 1) de 10 à 20 mμ.

Lorsque le radical méthyle est substitué en position *para*, le déplacement est plus grand que pour les positions *meta* et *ortho*. Les bandes d'absorption sont déplacées vers des longueurs d'ondes plus grandes (approximativement 10 mμ) et dû aux groupements $-O-CH_2-$, liés au noyau aromatique.

Les coefficients d'extinction ayant des valeurs de l'ordre 2000 correspondent aux absorptions caractéristiques des composés aromatiques de la même classe.

L'analyse thermogravimétrique des tris-éthers étudiés ne fait pas ressortir un processus de décomposition ou de réarrangement à des températures inférieures à celle d'ébullition.

PARTIE EXPÉRIMENTALE

Le bis(chlorométhyle) éther a été obtenu en passant un puissant courant d'acide chlorhydrique sur le paraformaldéhyde suspendu en acide sulfurique concentré.

Le phénol utilisé a été un produit commercial « Reactivul », l'-*o*-crésol un produit UCB, le *m*-crésol Toskat et le *p*-crésol Riedel de Haen. Le 2,3-, 2,5- et 2,6-xylénol un produit BDH, le 3,4-xylénol UCB et le 3,5-xylénol Loba Chemie-Wien.

Les spectres IR ont été obtenus en tablettes de KBr à l'aide d'un appareil UR-20, Karl Zeiss Jéna.

Les spectres UV ont été obtenus en solution de cyclohexane en utilisant un apareil CF Optica, Milano.

L'analyse thermogravimétrique a été effectuée à l'aide d'un dérivatographe de type Pauly.

LA SYNTHÈSE DU BIS(PHENOXYMÉTHYLE) ÉTHER

Dans un ballon de 50 ml, ayant deux cols, muni d'un réfrigérant ascendant et d'un thermomètre sont introduits, 3,765 g (1/25 moles) phénol, 1,660 g NaOH (1/25 moles) et 30 ml d'un mélange composé d'alcool-benzène (1 : 1 en volume). On chauffe au reflux jusqu'à la formation totale du phénoxyde de sodium et on distille 15 ml de mélange azéotrope d'alcool-eau-benzène.

On ajoute au phénoxyde de sodium anhydre, se trouvant dans le ballon, 2,300 g bis(chlorométhyle) éther et on chauffe pendant 3 heures au reflux. On laisse le mélange de réaction refroidir à la température ambiante. Le tris-éther formé est cristallisé. Le produit solide, comprenant aussi du chlorure de sodium, est séparé de la part liquide, par filtration. Le précipité déposé sur le filtre est lavé plusieurs fois avec de l'eau afin d'éliminer le NaCl et ensuite avec 1 ml d'alcool et séché. Il résulte 3,2 g. Le rendement est de 85%. Après deux recristallisations du mélange alcools-benzène (1 : 1 en volume) la température de fusion du bis(phénoxyméthyle) éther est $T_f = 81 - 83°$.

La synthèse des autres produits a eu lieu dans des conditions identiques.

HETEROCYCLIC DERIVATIVES WITH THIAZOLIC RINGS. I

SYNTHESIS OF 6-AMINOTHIAZOLO[4,5-f]INDAZOLE

C. TĂRĂBĂŞANU-MIHĂILĂ, L. FLORU, EUGENIA BALTĂ*) and
A. PREDESCU

Institute, Bucharest, Str. Polizu, 1**

Received November 28, 1972

A new possibility for obtaining 6-aminothiazolo [4,5-f] indazole and some derivated cationic and dispersion dyes has been investigated.

1. INTRODUCTION

In recent years, there has been an increasing trend toward introducing heterocyclic systems in the structure of cationic and dispersion dyes. Derivative dyes of benzothiazole, indazole and triazole have found large commercial applications because of their remarkable tinctorial properties.

The presence of the benzodithiazole systems I and II, studied by Kiprianov and Mihailenko, [1] confers special qualities and colours on the cationic dyes.

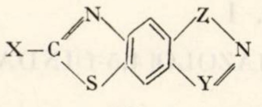
II

X= N=N−Ar

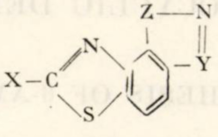
---

[1] A. I. Kiprianov and F. A. Michailenko, *Khim. geterotsikl. Soedinenyi* **2**, 270 (1967); *Chem. Abstr.*, **70**, 1269a (1969).

Based on these findings, we intend to obtain other heterocyclic systems III and IV which may be included in the structure of cationic and dispersion dyes



III



IV

where : $X = NH_2$, SH or substituted aryl
$Y = N$, CH, CHCl, CHBr
$Z = NH$, O, S

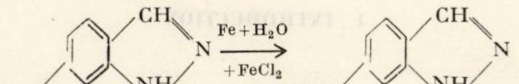
The present paper reports on the results of our experimental investigations regarding the synthesis of 6-aminothiazolo [4,5-f] indazole IV (III ; $Y = N$, $Z = CH_2$; $X = NH_2$), a compound which was obtained by Bellavita [2] in 1968 for pharmaceutical purposes ; it also suggests some possibilities for including this compound in the structure of the dyes.

2. RESULTS AND DISCUSSIONS

2.1. SYNTHESIS OF 6-AMINOTHIAZOLO[4,5-f]INDAZOLE

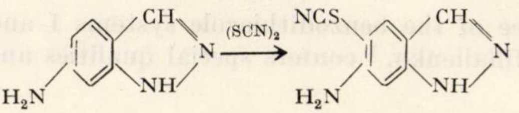
The compound was synthesized according to the following reaction sequence :

(1)

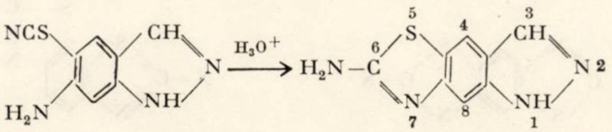


6-Nitroindazole was prepared by the method described by Meunier [3] (m.p. = 179 — 180°). Its reduction (1) to 6-aminoindazole occurred in aqueous medium with iron in the presence of iron chloride as electrolyte.

(2)



(3)



IV

---

[2] C. Bellavita, N. Martani and F. A. Amaldo, *Ann.Chim.* (*Ital.*), **58**, 823 (1968).
[3] J. Meunier, *Bull. Soc. chim. France*, **31**, 641 (1904).

The following reaction was used [2] as a dithiocyanate source :

$$2NH_4SCN + Br_2 = 2NH_4Br + (SCN)_2 \tag{4}$$

It is known [4] that reaction (4) is more rapid than the bromination reaction. For this reason, no bromination process occurs in synthesis making use of reaction (4) at a NH_4SCN to Br_2 molar ratio of over 3 : 1.

Bromination may appear in the case of a lower ratio between reactants. Thus, 3-bromo-6-aminothiazolo [4,5-f] indazole appears as a reaction (2) product at a 6-aminoindazole : NH_4SCN : Br_2 molar ratio of 1 : 2.5 : 6. Its presence is explicable since indazole as such brominates more readily in position 3 than in the benzene nucleus.[5]

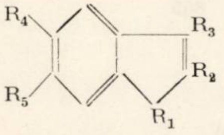
Copper thiocyanate used as a dithiocyanate source,[6] or the reaction between alkaline thiocyanate and sulphuryl chloride[7] also gave favourable results.

This method for 6-aminothiazolo [4,5-f] indazole synthesis is not mentioned in literature. We point out the fact that high-purity products have been obtained by using copper thiocyanate without running the risk of bromination.

$$2Cu(SCN)_2 \rightarrow 2CuSCN + (SCN)_2 \tag{5}$$

2.2. IR SPECTRA OF 6-NITRO- AND 6-AMINOINDAZOLE

Spectroscopic studies carried out by O'Sullivan [8] on type V compounds show that the variation of substitutes :



V

where : R_1, R_2, R_3 may be CH_2 NH, O, CO, SO_2, CH, N.

R_4 and R_5 produce hardly noticeable changes in the overall aspect of spectra, except for the appearance of their characteristic bands. Bands situated around 1600, 1460, 1390, 1310, 1270, 1250, 1200, 1160, 1100, 1060, 1020, 950, 890, 850, 800 and 750 cm^{-1} seem to be characteristic of the type V heterocyclic systems.[9]

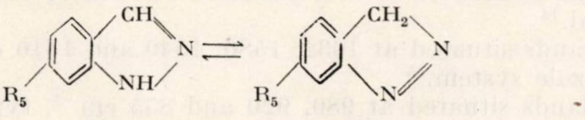
[16] E. Baltă, *Rev. Roumaine Chim.*, **17**, 1241 (1972).

They also appear in the case of 6-aminoindazole (V; $R_1 = NH$; $R_2 = N$; $R_3 = CH$; $R_4 = H$; $R_5 = NH_2$) with minor changes (table 1).

Indazole derivatives may exist under two tautomeric forms: VI and VII.



VI VII

Since no accurate spectral differentiation can be made between C=N and N=N frequencies [10] the IR spectra analysis did not establish — in the case of these compounds — the tautomeric form which contributes most significantly to the overall mesomerism of the molecule. This band is situated at 1620 cm^{-1} for compounds VI and VII (table 1).

The presence of ν_{CH} at 2920 cm^{-1} in the case of 6-nitroindazole (an imperceptible band for 6-aminoindazole being probably included in the large band at 3130–2980 cm^{-1}) supports the structure VI which we consider as being the most probable.

In the structure of compounds VI, $N-H\ldots N$ hydrogen bonds make an important contribution. [9] The presence of the above mentioned large band certifies the involvement of NH group in strong intermolecular hydrogen bonds. They are stronger in the case of 6-aminoindazole than in that of 6-nitroindazole where ν_{NH} is certainly situated at 3160 cm^{-1}. This value is lower than in the case of the indigo itself ($\nu_{NH} = 3246\ cm^{-1}$),[11] a molecule in which the contribution of hydrogen bridges is considerable.[12]

The position of $\nu_{NO_2\ sym.}$ at 1352 and $\nu_{NO_2\ asym.}$ at 1532 cm^{-1} — therefore at normal frequencies [9] — suggests that these groups are not involved in hydrogen bonds.

Amino groups were also revealed for 6-aminoindazole by vibrations $\nu_{NH_2\ sym.}$ at 3360 cm^{-1} and $\nu_{NH_2\ asym.}$ at 3440 cm^{-1}.

Since the substituted indazoles are sparingly soluble in the usual solvents, a detailed study of the association by means of the hydrogen bonds was not possible.

2.3. IR SPECTRUM OF 6-AMINOTHIAZOLO[4,5,-f]INDAZOLE. IV

Considering O'Sullivan's[8,9] findings with regard to compounds V it may be assumed that the spectrum of 6-aminothiazolo-[4,5-f]indazole must retain the typical 2-aminobenzothiazole bands and those of the indazole cycle unless substitutes R_4 and R_5 cause major changes in the spectrum. Table 1 presents the spectral data established by Surish and coworkers for 2-aminobenzothiazole, [13] by Bonnier and coworkers, for benzothiazole[14] and the IR spectrum determined by us for compound IV.

By comparing these data it may be seen that above assumption is a real one.

The following bands have been assigned in the spectrum of compound IV :

1. Bands situated at 658, 630 and 620 cm^{-1}, corresponding to the C$-$S bond.[13]

2. Bands situated at 1632, 1580, 1540 and 1510 cm^{-1}, typical of the benzothiazole system.[15]

3. Bands situated at 980, 920 and 855 cm^{-1}, typical of the thiazole system.[6]

4. All the bands typical of the indazole system : $\nu_{NH} = 3160\ cm^{-1}$, $\nu_{CH}=3065\ cm^{-1}$ and 2935 cm^{-1} and also all the bands situated within the 1380 $-$ 1071 and 850 $-$ 720 cm^{-1} ranges.

5. Bands $\nu_{NH_2\ asym.}$ at 3380 cm^{-1} and $\nu_{NH_2\ sym.}$ at 3315 cm^{-1}, which confirms the presence of amino groups.

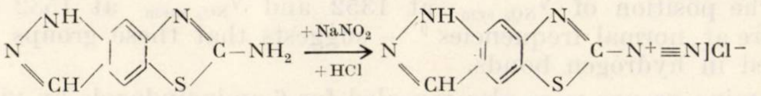
The fact that the IR spectrum of compound IV obeys O'Sullivan's findings, proves that even if type V heterocycles are included in compactly-condensed heterocyclic systems, they will keep their individuality, from IR absorption viewpoint.

3. DERIVATIVE DYES OF SYSTEM IV

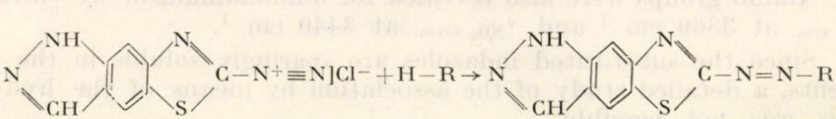
3.1. DISPERSION DYES

These compounds were obtained by the following reaction sequence :

(6)



(7)



VIII

R = substituted aromatic or heterocyclic residue.

Type VIII products proved to be dispersion dyes with remarkable properties, used for dyeing of polyester fibres and cellulosis acetate.

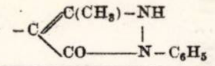
Table 2 lists data concerning the synthesis and the tinctorial properties of these compounds.

3.2. CATIONIC DYES

All type VIII structures will become cationic dyes by methylation at one of the nitrogen atoms included in the heterocycle and may be used for dyeing of polyacrylonitrile fibres.

Table 2

Data concerning the synthesis and tinctorial properties of the compounds VIII with R = p – C_6H_4 – NXY or with T =



$-C\langle\begin{smallmatrix}C(CH_3)-NH\\ |\\ CO\text{———}N-C_6H_5\end{smallmatrix}$

X	Y	Obtaining of the diazonium salt of the compound IV					Coupling reaction				Tinctorial results	
		Comp. IV g	Solvent (ml)	$NaNO_2$ g	Temp. °	Time hrs	R – H g	Solvent (ml)	Temp. °	%	Colour on cellulose acetate	Colour on polyester fibres

T		10	H_3PO_4 (25)	2.4	–15	16	15	$HCON(CH_3)_2$ (40)	–5	80	yellow	yellow

Methylation has been carried out with dimethylsulfate in an aqueous medium at 65 — 70°.

Although there are three possible methylations (the nitrogen atoms from positions 1, 2 and 4), the reaction results in a unitary product; this fact was proved by paper chromatography analysis.

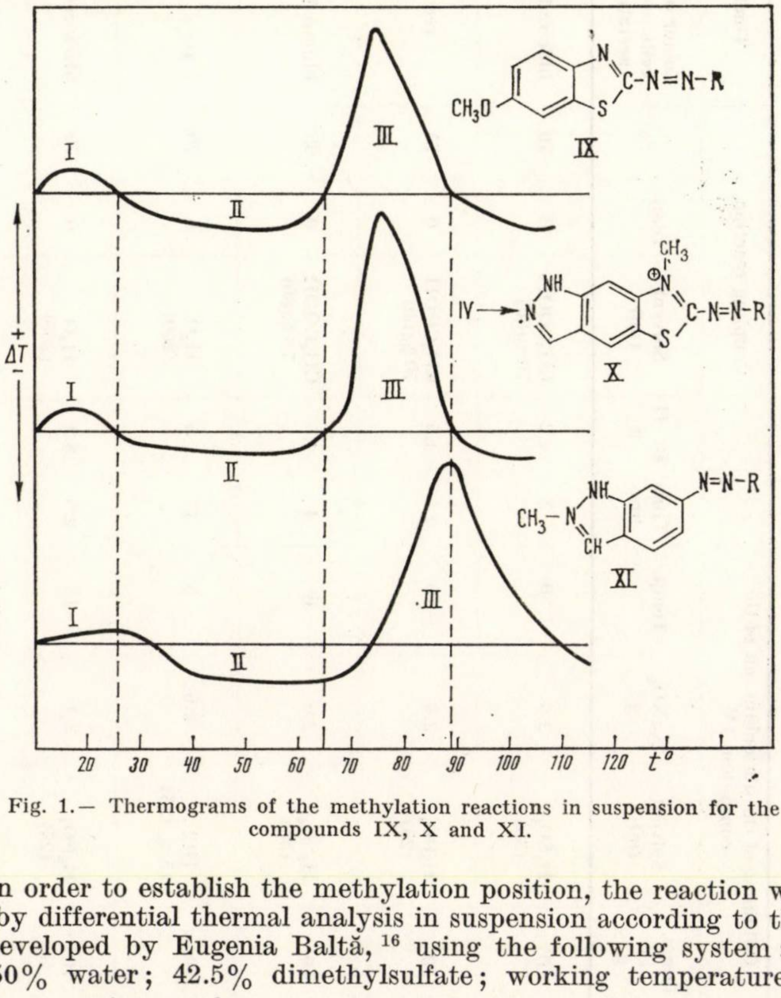

Fig. 1.— Thermograms of the methylation reactions in suspension for the compounds IX, X and XI.

In order to establish the methylation position, the reaction was followed by differential thermal analysis in suspension according to the method developed by Eugenia Baltă, [16] using the following system: 7.5% dye; 50% water; 42.5% dimethylsulfate; working temperature: 70°.

Comparative results are presented in figure 1 for compounds IX, IV and XI.

As reflected by the charts, a great similarity has been found between the methylation thermogram of compounds IX and X and also a clear-cut difference with respect to pigment XI.

The three common effects—two exo- and one endothermal—may be assigned as follows: [16]

I. A solvation exothermal effect of the pigment in water or dimethylsulfate;

II. An endothermal effect due to the decomposition of the transition product typical of the SN-2 mechanism.

III. An exothermal effect due exclusively to the hydrolysis of dimethylsulfate.

The beginning of the fourth thermal effect (endothermal) suggests the appearance of protonation at one of the protonation centers existing in the molecule.

Table 3

Tinctorial properties of the compounds X with $R = p-C_6H_5-NXy$

X	Y	Colour on polyacrylonitrile fibres
H	CH_3	blue-red
CH_3	CH_3	blue
H	C_2H_5	blue-red
C_2H_5	C_2H_5	blue
C_2H_5	C_2H_4OH	blue-violet

The perfect overlapping of the temperature ranges including the three effects for compounds IX and IV leads us to assign the structure X to the methylated compound, in which the quaternary group is localized on the thiazole cycle.

Table 3 shows the results obtained by dyeing of polyacrylonitrile fibres with type X products. The synthesis conditions are identical with those required for the differential thermal analysis in suspension.

4. EXPERIMENTAL

SYNTHESIS OF 6-AMINOTHIAZOLO[4,5-f]INDAZOLE

Introduce 620 ml glacial acetic acid into a 2.5 liter 3-neck flask equipped with stirrer, reflux refrigerator and thermometer, having the possibility to cool to 10° and add thereafter 121.6 ammonium sulfocyanide with stirring until a fine suspension results. Subsequent addition of 200.4 g crystallized copper sulfate gives a black coloured precipitate, $Cu(SCN)_2$. Add 20 g 6-aminoindazole at the same temperature. Continue stirring for 90 minutes at 10° after adding the reactants and increase the temperature to 40° over the next 90 minutes. Keep the reaction mass at this temperature for 6 hours with stirring. The mass turns yellowish-brown when the reaction is completed.

Dilute it then with 1500 ml water heated to 80°, keep under stirring for another 15 minutes. The reaction mass takes the aspect of a yellow suspension and is filtered. Stirr the filtrate with 6 g animal charcoal, heat it to 80° and filter it. After cooling to 20°, the filtrate is alkalinised with solid $NaHCO_3$ up to pH 8.5. Filter the resulting precipitate and wash with cold water until a neutral pH is obtained. One obtains 14 – 17 g of product V. Yield 60 – 70 %; melting point above 300°.

The elementary analysis for $C_8H_6N_4S$: C % :*calc.* : 50.53 ; *found* : 50.18 ; H % : *calc.* : 2.63 ; *found* :2.07 ; N % : *calc.* : 29.47 ; *found* : 29.80 ; S % : *calc.* :16.84 ; *found* : 16.75.

IR spectra were taken in a KBr disk using a UR-10 spectrophotometer.

5. CONCLUSIONS

1. A new method was established for the synthesis of 6-aminothiazolo [4,5-f] indazole by using copper sulfocyanide as a dithiocyanate source.

2. The introduction of this heterocycle in the structure of dispersion and cationic azo-dyes results in products with remarkable tinctorial properties which may be used for dyeing of hydrophobe synthetic fibres. They have not been reported in the literature so far.

γ-KETO ACIDS IN THE PFITZINGER REACTION

A. M. EL-ABBADY*, M. A. OMARA and N. G. KANDIL

Department of Chemistry, University College for Girls
A'in Shams University, Cairo, Egypt

Received July 26, 1972

β-Aroylpropionic acids (I, R = H, CH_3, Cl) are condensed with isatin under Pfitzinger conditions to give the corresponding 2-aryl-3-carboxymethyl cinchoninic acids (II). These are esterified with diazomethane to give the corresponding dimethyl esters (III). Acetyl chloride gives with (II) the anhydrides (IV), but acetic anhydride and fused sodium acetate give (IV), together with 5-acetoxybenz (c) acridines (V). The acids (II) on heating in vacuum just above their melting points give 5,6-dihydro-5-oxo-benz(c) acridines (VI), but on treatment with boiling nitrobenzene they give 2-aryl-3-methyl cinchononic acids (VII). The structure of all the products is inferred from their analytical data, infrared spectra and chemical properties.

As far as we are aware only α-keto acids and α-keto esters as pyruvic acid, substituted pyruvates [1] and oxaloacetic esters [2] have been tried to react with isatin and substituted isatin under the conditions of Pfitzinger reaction. [3]

In the present investigation the Pfitzinger reaction between γ-keto acids and isatin is reported. β-Aroylpropionic acids namely β-benzoylpropionic acids (I, R = H), β-toloylpropionic acid (I, R = CH_3) and β-p-chlorobenzoylpropionic acid (I, R = Cl) are condensed with isatin in the presence of alcoholic potassium hydroxide solution (33%). Good yields of 2-aryl-3-carboxymethylcinchoninic acids (II, R = H, $-CH_3$, Cl) were obtained by this treatment. These dibasic acids were found to exist as zwitterions as indicated from their infrared spectra [4] which revealed absorption bands at : 3400–3100 cm^{-1} characteristic of the stretching frequency of the OH of the dimeric carboxyl groups ; 1720, 1630, 1500 cm^{-1} characteristic of the stretching frequencies of carbonyl of the carboxyl groups, of the aromatic rings skeleton, and of the antisymmetrical carboxylate anion respectively; 950, 830, 770, 740 and 690 cm^{-1} characteristic of the out-of-plane bending frequencies of OH for the carboxyl groups and of two, four and five adjacent aromatic hydrogen atoms respectively; 725cm^{-1} characteristic of the stretching frequency for the carbon chlorine bond.

---

* Present address : Head of the Chemistry Department, Faculty of Science at Tanta Egypt.

[2] J. Halberkann, *Ber. dtsch. chem. Ges.*, **54**, 3079 (1921).

[3] W. Pfitzinger, *J. prakt. Chem.*, **33**, 100 (1886).

[4] L. J. Bellamy, "The Infrared Spectra of Complex Molecules", Methuen, London, 1958.

Usual methods of esterification of these dicarboxylic acids using methanol and concentrated sulphuric acid or hydrogen chloride gas were found to give unsatisfactory results. Treatment of the acid chlorides with methanol also failed to react.

Esterification was, however, carried out using diazomethane [5] where the diesters, methyl 3-carbomethoxymethyl-2-arylcinchoninates (III) were obtained in good yield. The structure of these diesters was inferred from their analytical data, and from their infrared absorption spectra which showed the following bands: 1745, 1735, 1600, 1580, 1500, 830, 770, 750, 700 and 725 cm^{-1}, characteristic of ν C=O of saturated and aromatic esters, of the aromatic ring skeleton, of the aromatic γ-CH of two, four and five adjacent hydrogen atoms, and of the ν C—Cl respectively.

3-Carboxymethyl-2-aryl-cinchoninic acids (II, R = H, CH$_3$) were converted into their anhydrides (IV, R = H, CH$_3$) by refluxing with acetyl chloride, but 3-carboxymethyl-2-*p*-chlorophenyl-cinchoninic acid (II, R = Cl) required treatment with acetic anhydride at room temperature to be converted to its anhydride (IV, R = Cl).

The infrared spectra of these anhydrides show the doublet stretching frequencies of the carbonyl at 1740 and 1660 cm^{-1} besides the rest of the usual bands. Although these doublets have lower stretching frequencies than those for six-membered ring anhydrides [6] which absorb at 1821 and 1774 cm^{-1}, yet they are similar to those of homophthalic anhydride which showed doublet at 1760 and 1680 cm^{-1}.

Treatment of the dibasic acids (II) with sodium acetate in acetic anhydride [7] yielded 5-acetoxy-benz (c) acridine or its 3-methyl-or 3-chloroderivatives (V) contaminated with the corresponding anhydrides (IV). The structure of acridines (V) was inferred from their analytical data; and infrared spectra which showed the characteristic bands of ν C = O and ν C — O of the acetoxy group at 1740, 1730, 1240 and 1150 cm^{-1} respectively.

Decarboxylation of the dibasic acids (II) was carried out by thre methods:

(a) Heating just above their melting points under reduced pressure,[8] whereupon 5,6-dihydro-5-oxo-benz (c)acridine and its derivatives (VI) were obtained. The structure of these acridines was inferred from: i — Their analytical data. ii — Their stability in hot sodium hydroxide solution. iii — Their infrared spectra which showed two bands at 1750 and 1660 cm^{-1} characteristic of the stretching frequencies of ketonic carbonyl group and aromatic ring skeleton respectively.

(b) Heating in nitrobenzene [9] gave 2-aryl-3-methylcinchoninic acids (VII). The structure of these monobasic acids was confirmed from

their analytical data and their infrared spectra which showed bands at 3400 (br) and 1620 cm^{-1} with a broad base, (1700–1550 cm^{-1}) characteristic of stretching frequencies of hydroxyl and carbonyl groups of dimeric carboxylic acids.

Furthermore, 3-methyl-2-phenylcinchoninic acid (VII; R = H) was prepared authentically [10] and was decarboxylated by the first method to 3-methyl-2-phenylquinoline. [10,11]

(c) Heating with copper-bronze [7] in quinoline or with sodalime gave unsatisfactory results.

EXPERIMENTAL[12]

Pfitzinger reaction between isatin and β-aroylpropionic acids. General Procedure:

β-Aroylpropionic acids (0.04 mole) was added to a solution of isatin (0.04 mole) in 33% ethanolic potassium hydroxide solution (100 ml) and the mixture was refluxed for about 12 hours. The cooled solution was rendered acidic by dilute hydrochloric acid, then made just alkaline with potassium hydroxide solution and finally acidic with acetic acid. The precipitate was collected and crystallized from the suitable solvent.

3-CARBOXYMETHYL-2-PHENYLCINCHONINIC ACID (II, R=H)

The product obtained was crystallized from ethanol to give colourless crystals melted at 277°C. Yield 8 g (65 %).

Anal. *calcd.* for $C_{18}H_{13}O_4N$: C, 70.4 ; H, 4.3 ; N, 4.5
Found : C, 70.8 ; H, 4.4 ; N, 5.4 %.

3-CARBOXYMETHYL-2-(*p*-TOLYL)CINCHONINIC ACID (II, R=CH$_3$)

The product obtained was crystallized from ethanol to give colourless crystals, m.p. 264°C. Yield 8 g (53 %).

Anal. *calcd.* for $C_{19}H_{15}O_4N$: C, 71.02 ; H, 4.7 ; N, 4.4.
Found : C, 71.9 ; H, 5.3 ; N, 4.4 %.

3-CARBOXYMETHYL-2-(*p*-CHLOROPHENYL)CINCHONINIC ACID (II, R=CL)

The product obtained was crystallized from ethanol to give colourless crystals, m.p. 255°C. Yield 9 g (66 %).

Anal. *calcd.* for $C_{18}H_{12}O_4NCl$: C, 63.2 ; H, 3.5 ; N, 4.0 ; Cl, 10.3.
Found : C, 62.5 ; H, 4.2 ; N, 4.6 ; Cl, 10.3 %.

Esterification of 3-carboxymethyl-2-arylcinchoninic acids (II) General procedure:

The diacid (1g) was treated with diazomethane (from 10 g nitrosomethyl urea) in ether (250 ml). The ethereal solution was left overnight in an ice chest, washed with aqueous sodium carbonate, dried over anhydrous sodium sulphate, filtered and evaporated nearly to dryness. The residual product obtained was crystallized from the suitable solvent.

METHYL 3-CARBOXYMETHYL-2-PHENYLCINCHONINATE (III, R=H)

The product obtained was crystallized from petroleum ether (b.p.60 – 80°) in colourless crystals, m.p. 100–101°C. Yield 0.8 g (73 %).

Anal. *calcd.* for $C_{20}H_{17}O_4N$: C, 71.6 ; H,5.1 ; N, 4.1.
Found : C, 70.9 ; H, 5.1 ; N, 3.7 %.

METHYL 3-CARBOMETHOXYMETHYL-2-(*p*-TOLYL)CINCHONINATE (III, R=CH$_3$)

The product obtained was crystallized from ethanol in glittering colourless crystals, m.p. 105 – 106°C. Yield 0.8 g (73.6 %).

Anal. *calcd.* for $C_{21}H_{19}O_4N$: C, 72.2 ; H, 5.4 ; N, 4.0.
Found : C, 71.9 ; H, 5.7 ; N, 4.0 %.

METHYL 3-CARBOMETHOXYMETHYL-2-(*p*-CHLOROPHENYL)CINCHONINATE (III, R=Cl)

The product obtained was crystallized from petroleum ether (b.p.60 – 80°) in colourless needles, m.p. 99 – 100°C. Yield 0.8 g (73.9 %).

Anal. *calcd.* for $C_{20}H_{16}O_4NCl$: C, 64.9 ; H, 4.3 ; N, 3.7 ; Cl, 9.6.
Found : C, 64.0 ; H, 4.8 ; N, 4.5 ; Cl, 9.6 %.

ACTION OF ACETYL CHLORIDE ON THE 3-CARBOMETHOXYMETHYL-2-ARYLCINCHONINIC ACIDS

General procedure :

The diacid (1 g) was treated with acetyl chloride or acetic anhydride (10 ml). After evaporation, the residue was dissolved in ether and the ethereal solution washed with sodium carbonate solution then dried over anhydrous sodium sulphate. The product obtained was crystallized from the suitable solvent.

3-CARBOXYMETHYL-2-PHENYLCINCHONINIC ACID ANHYDRIDE (IV, R = H)

The diacid (II, R = H) was refluxed with acetyl chloride for 5 hours. The product obtained was crystallized from benzene/petroleum ether (b.p. 40 – 60°) as yellow needles, m.p. 170°. Yield 0.6 g (66 %).

Anal. *calcd.* for $C_{18}H_{11}O_3N$: N, 4.8.
Found : N, 5.1 %

3-CARBOXYMETHYL-2-(*p*-TOLYL)CINCHONINIC ACID ANHYDRIDE (IV, R=CH_3)

The diacid (II, R = CH_3) was refluxed with acetyl chloride for 1 hour. The product so obtained was crystallized from petroleum ether (b.p. 80 – 100°), in yellow needles, m.p. 170 – 171°. Yield 0.85 g (94 %).

Anal. *calcd.* for $C_{19}H_{13}O_3N$: C, 75.24 ; H, 4.3 ; N, 4.6.
Found : C, 75.6 ; H, 4.9 ; N, 4.8 %.

3-CARBOXYMETHYL-2-(*p*-CHLOROPHENYL)CINCHONINIC ACID ANHYDRIDE (V, R = Cl)

The diacid (II, R = Cl) was dissolved in cold acetic anhydride and left at a room temperature for 2 days. The product obtained was crystallized from benzene/petroleum ether (b. p. 40 – 60°), as a yellow powder, m.p. 173 – 74°C. Yield 0.05 g (5 %).

Anal. *calcd.* for $C_{18}H_{10}NO_3Cl$: N, 4.4.
Found : N, 4.4 %.

Hydrolysis of the anhydrides (IV, R = H, CH_3 and Cl) with 10 % aqueous potassium hydroxide solution gave back the diacids (II, R = H, CH_3 and Cl), mixed m.p. undepressed.

CYCLISATION OF THE 3-CARBOXYMETHYL-2-ARYLCINCHONINIC ACIDS

General procedure :

A mixture of the diacid (0.02 mole), fused sodium acetate (2 g) and acetic anhydride (25 ml) was refluxed for 5 hours. After removal of acetic anhydride under reduced pressure water was added. The solid formed was digested with ether. The ethereal solution was dried over anhydrous sodium sulphate, and evaporated to give the anhydrides (IV, R = H, CH_3, Cl). This was proved by melting and mixed m.p. with the anhydrides obtained by treating the dibasic acids (II) with acetyl chloride or acetic anhydride.

The ether insoluble fraction was crystallized from the suitable solvent.

5-ACETOXYBENZ(c)ACRIDINE (V, R =H)

The product obtained was crystallized from benzene as yellow needles, m.p.300°. Yield 2.5 g (47%).

Anal. *calcd.* for $C_{19}H_{13}NO_2$: C, 79.4 ; H, 4.5 ; N, 4.8.

Found : C, 79.9 ; H, 4.1 ; N, 4.5%.

5-ACETOXY-3-METHYLBENZ(c)ACRIDINE (V, R = CH_3)

The product insoluble in ether was crystallized from bezene as yellow crystals, m.p. above 312°C. Yield 2.8 g (40%).

Anal. *calcd.* for $C_{20}H_{15}NO_2$: C, 79.7 ; H, 5.0 ; N, 4.7.

Found : C, 80.6 ; H, 4.4 ; N, 4.9%.

5-ACETOXY-3-CHLOROBENZ(C)ACRIDINE (V, R=Cl)

The product insoluble in ether was crystallized from benzene as yellow needles, m.p. 280°C. Yield 2.8 g (46%).

Anal. *calcd.* for $C_{19}H_{12}NClO_2$: C, 70.9 ; H, 3.7 ; N, 4.4 ; Cl, 11.

Found : C, 71.8 ; H. 3.6 ; N, 4.9 ; Cl, 11.8%.

PYROLYSIS OF 3-CARBOXYMETHYL-2-ARYLCINCHONINIC ACIDS

General procedure :

The diacid (1 g), placed in a test tube fitted with a cold finger, was heated at about 20° above its m.p. under diminished pressure (10 mm/Hg). The compound melted, evolution of gases was observed and a dark redish-brown liquid was formed. This liquid was kept under these conditions for about half an hour. The solid obtained on cooling was extracted with ether. The ethereal solution was washed with sodium carbonate solution, dried over anhydrous sodium sulphate, and filtered. After removal of the solvent the residue was crystallized from the suitable solvent.

5,6-DIHYDRO-5-OXOBENZ(C)ACRIDINE (VI, R=H)

The product was crystallized from petroleum ether (b.p. 40 – 60°) in pale brown crystals ; m.p. 172 – 74°. Yield 0.6 g (85%).

Anal. *calcd.* for $C_{17}H_{11}NO$: C, 83.3 ; H, 4.5.

Found : C, 84.1 ; H, 4.6%.

5,6-DIHYDRO-3-METHYL-5-OXOBENZ(c)ACRIDINE (VI, R= CH_3)

The product obtained was crystallized from benzene in yellow balls, m.p. 202°C. Yield 0.6 g (75%).

Anal. *calcd.* for $C_{18}H_{13}NO$: C, 83.3 ; H, 5.0 ; N, 5.4.
Found : C, 83.8 ; H, 5.1 ; N, 5.7%.

3-CHLORO-5,6-DIHYDRO-5-OXOBENZ(c)ACRIDINE (VI, R=Cl)

The product obtained was crystallized from benzene/petroleum ether (b.p. 40 – 60°), as brown powder, m.p. 226 – 27°C. Yield 0.6 g (75%).

Anal. *calcd.* for $C_{17}H_{10}NOCl$: 72.9 ; H, 3.5 ; N, 5.0 ; Cl, 12.3.
Found : C, 72.7, H, 3.7 ; N, 5.0 ; Cl, 12.7%.

ACTION OF BOILING NITROBENZENE ON 3-CARBOXYMETHYLCINCHONINIC ACIDS

General procedure :

The diacid (1 g) was refluxed in nitrobenzene (20 ml) for 1 hour. The solid separated on cooling to room temperature was filtered off and crystallized from a suitable solvent.

3-METHYL-2-PHENYLCINCHONINIC ACID[10] (VII, R = H)

The product obtained was crystallized from ethanol to give colourless needles, m.p. 299°. [10] Yield 0.4 g (50%).

A sample of the product was decarboxylated by heating under vacuum to give the known 3-methyl-2-phenylquinoline, m.p. 50° from benzene/petroleum ether, b.p. 40 – 60° (ref. [10] m.p. 52 – 53° (43°).

Picrate derivative, m.p. 205° (from benzene). [11]

3-METHYL-2-(*p*-TOLYL)CINCHONINIC ACID (VII, R=CH_3)

The product obtained was crystallized from benzene to give colourless needles, m.p 295°C. Yield 0.5.g (62%).

Anal. *calcd.* for $C_{18}H_{15}NO_2$: C, 77.9 ; H, 5.4 ; N, 5.0.
Found : C, 78.0 ; H, 5.5 ; N, 5.3%.

2-(*p*-CHLOROPHENYL)-3-METHYLCINCHONINIC ACID (VII, R=Cl)

The product obtained was crystallized from ethanol to give colourless crystals, m.p. 310°. Yield 0.4 g (50%).

Anal. *calcd.* for $C_{17}H_{12}NO_2$: N, 4.6 ; Cl, 11.9.
Found : N, 4.5 ; Cl, 11.2%.

THE POLYMERIZATION OF N-VINYLCARBAZOLE BY THE SYSTEMS ACRYLONITRILE-$ZnCl_2$ AND ACRYLONITRILE-$HgCl_2$

D. S. VASILESCU, MARIA ŞTEFĂNESCU and AL. BĂLĂNESCU

Laboratory of Macromolecular Chemistry, Polytechnic Institute, Bucharest, Romania

Received September 21, 1972

The polymerization of N-vinylcarbazole in the presence of the acrylonitrile-$ZnCl_2$ complex or acrylonitrile-$HgCl_2$ homogeneous mixture was studied. The polymerization occurs very fast; no alternating copolymers were obtained. The process is cationic.

1. INTRODUCTION

The complexes of acrylonitrile or methyl methacrylate with $ZnCl_2$ were obtained first by Imoto. [1] The influence of metal salts on the reactivity of vinyl monomers has been studied extensively by a great number of investigators in recent years. [2–4]

Several authors have found that some complexes may be polymerized to obtain stereoregular polymers [2]; on the other hand other authors have prepared alternating copolymers of high regularity by copolymerization of complexed monomers with electron-donating monomers.[3–4] Gaylord and his co-workers [5] reported data, in order to elucidate the behaviour of these systems.

The complex from a vinyl monomer (containing nitrile or ester groups) and a metal salt (such as $ZnCl_2$, $Et_{1.5}AlCl_{1.5}$, $SnCl_4$, $AlCl_3$) acts generally as an electron acceptor. The polymerization of N-vinylcarbazole by electron acceptors is well known [6]; Plesch and his co-workers, [7] have studied the polymerization of N-vinylcarbazole (NVC) by $HgCl_2$ using chlorobenzene as solvent.

In this work we present results concerning the polymerization of NVC by the acrylonitrile-$ZnCl_2$ and acrylonitrile-$HgCl_2$ systems.

2. EXPERIMENTAL

a. MATERIALS

NVC "FLUKA" was three times recrystallized from *n*-hexane and dried in vacuum at 30°, 48 h (m.p. = 64.2°).

$ZnCl_2$ was dried in vacuum at 200°; $HgCl_2$ was sublimated in vacuum. Acrylonitrile (AN) was distilled, dried over calcium hydride and recondensed in vacuum over dried $ZnCl_2$ (or $HgCl_2$). The complexes were prepared according to the procedures reported by Imoto [1] and put in ampoules; the presence of moisture was avoided.

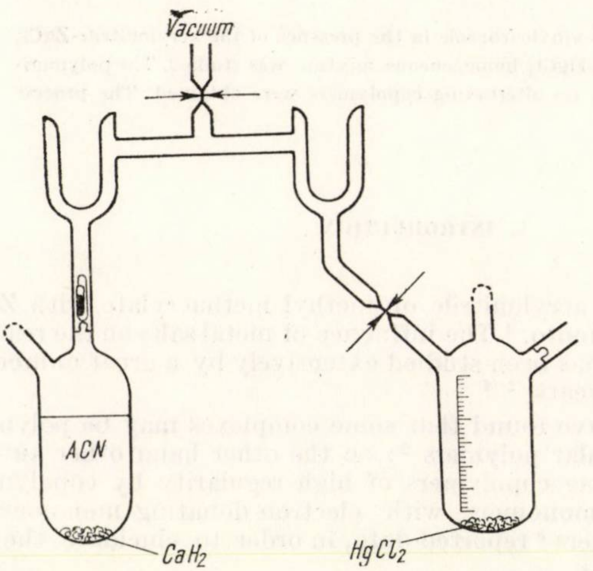

Fig. 1. — Installation for the catalyst solution.

For the determination of the salt concentration in AN, analytic methods were used.

An amount of $HgCl_2$-AN solution was evaporated in vacuum, AN condensing in a trape frozen in liquid nitrogen; the solid product consists in $HgCl_2$, fact demonstrated by performed analyses (melting point, cryoscopic molecular weight in dioxane).

Toluene (T), chlorobenzene (CB), dioxane (D), dimethylformamide (DMF). acetonitrile, styrene (S), *n*-butylvinylether (NBVE) and *t*-butylvinylether (TBVE) were purified by distillation and dried by conventional ways; methanol was used without special purification.

[7] M. A. HAMID, M. NOWAKOWSKA and P. H. PLESCH, *Makromol. Chem.*, 132, 1 (1970).

b. POLYMERIZATION PROCEDURE

The polymerizations were carried out in a vacuum-dilatometer with two charging arms and pressure-compensator, whose construction and operation way have been described.[8] Other tests were carried out in test tubes with two arms too, which were connected to a short vacuum assembly. The glass ampoules (or dilatometer's tube) were frozen in liquid nitrogen, degassed several times and sealed under vacuum. The tubes were put at the desired temperature in a thermostated bath; the polymerization may begin with the mixing. After an appropriate time of polymerization the tube (or dilatometer) was opened and the polymer was precipitated by pouring the solution into a large amount of cold methanol. After filtration, polymers were reprecipitated, dried and weighed.

c. ANALYSES OF POLYMERS

Molecular weights (MW) of these products were determined by viscosimetric ways[9] using an Ubbelohde viscometer; IR absorption spectra (recorded on a UR-10 spectrophotometer) and nitrogen contents (micro-Dumas method), confirm all methanol-reprecipitated products as poly-N-vinylcarbazole.[10]

3. RESULTS AND DISCUSSION

We carried out the polymerization of N-vinylcarbazole in toluene or other solvents using a complex AN-$ZnCl_2$ (molar ratio AN/$ZnCl_2$ = = 20, analytic determination).

Table 1

NVC polymerization by the complex AN-$ZnCl_2$

No	$\frac{Zn}{NVC}\,10^2$	NVC mole/l	Solvent	Temp. (°)	Time (min)	Yield (%)	[η] (dl/g)	M.W.
1	2	0.2	T	0	15	14.4	—	—
2	3	0.2	T	0	15	24.8	0.418	246 000
3	5	0.2	T	0	15	38.6	0.375	170 000
4	10	0.2	T	0	15	64.3	0.454	289 000
5	10	0.5	DMF	0	240	traces	—	—
6	5	1.0	CB	0	15	62.5	0.545	398 000
7	10	1.0	D	15	60	traces	—	—

As one can see from data given in Table 1, polymerization rates are fast and polymers are obtained in high yields with a remarkable molecular weight; the dependence of molecular weight on concentrations or conversion is negligibly small. It may be seen that the polymerization rate increases proportionally with the AN-$ZnCl_2$ complex concentration.

[10] O. F. Solomon, I. Z. Ciută and N. Cobianu, *J. Polymer Sci.*, B, **2**, 311 (1964).

When the complex acetonitrile-$ZnCl_2$ was used in equivalent concentrations no polymerization occurred; $ZnCl_2$, only, in equivalent concentrations too, produced nonfiltrable traces of polymer.

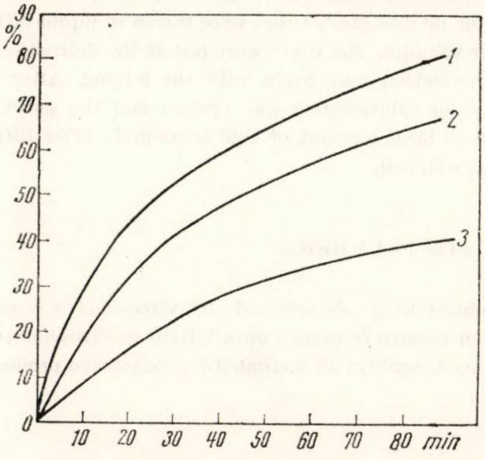

Fig. 2. — Conversion against time for the NVC polymerization by the complex AN-$ZnCl_2$; [NVC] = 0.2 mole/l; t = 0°; solvent, toluene;

1, $[ZnCl_2]/[NVC] = 5 \times 10^{-2}$; *2*, $[ZnCl_2]/[NVC] = 3 \times 10^{-2}$; *3*, $[ZnCl_2]/[NVC] = 2 \times 10^{-2}$.

The data from Table 1, and the tests with acetonitrile-$ZnCl_2$ or only with $ZnCl_2$, show that the effective catalyst is the complex AN-$ZnCl_2$.

The same behaviour can be seen in the presence of other electron-donating monomers.

Table 2

Polymerization of NVC in the presence of various comonomers (All polymerizations were made with the complex $AN/ZnCl_2 = 20$, in toluene at 0°; $ZnCl_2/NVC = 5 \times 10^{-2}$)

No	NVC mole/l	Comonomer mole/l		Time (min)	Yield (%)	[η] (dl/g)	M.W.
8	0.2	S	0.8	60	27.0	0.336	186 000
9	0.2	S	0.8	120	40.7	0.362	239 000
10	0.5	S	0.5	120	71.5	0.532	380 000
11	0.2	NBVE	0.8	60	traces	—	—
12	0.5	TBVE	0.5	120	28.5	—	—

All products are poly-N-vinylcarbazole. When a mixture of $HgCl_2$-AN is evaporated in vacuum, the obtained solid product is $HgCl_2$. This shows that either no complex was formed between $HgCl_2$ and AN, or that the complex formation has an equilibrium character. The adding of a concentrated $HgCl_2$ solution in AN over a toluene solution of NVC leads to the very fast polymerization of NVC.

We therefore used a small ratio of $HgCl_2$/AN (1/500) and an experimental technique in which the contact with moisture was avoided. Since the great disponibility of NVC towards cationic polymerization is known, we carried out tests (Table 3) to verify if the effective agent of initiation is AN, $HgCl_2$ or their mixture.

The product isolated in experiment 16 does not contain styrene units and consists only in poly-N-vinylcarbazole ; in the presence of AN, without $HgCl_2$, at 0°, no polymer formation could be observed (17-th exp.).

Table 3

Polymerization of NVC in various solvents, in argon medium ; monomer concentration : 0.5 mole/l; temperature : 0°

No	Solvent	$HgCl_2$/NVC	Time (min)	Yield (%)	Obs.
13	DMF	10^{-2}	60	0	—
14	CB	10^{-2}	15	57	—
15	T	5×10^{-3}	15	17	a
16	T	5×10^{-3}	15	32	b
17	T	0	15	0	c

a) The test was carried out in the absence of AN ; $HgCl_2$ was put on the wall of tube from acetone solution.

b) The mixture are containing styrene, (S)=0.5 mole/l, which does not polymerize.

c) The test was made in the absence of AN-$HgCl_2$ mixture, by adding only the corresponding quantity of AN (AN/NVC = 2.5).

These data permit us to affirm that $HgCl_2$ is implied in polymerization and the formed cation, which is not strong, may initiate the polymerization of NVC, but not that of styrene ; this fact is demonstrated also by the inhibition of the process in DMF, in spite of the fact that polymerizations of NVC in DMF under the influence of slight Lewis acids [6] are known.

Table 4

NVC polymerization in toluene at 0° ; monomer concentration = 0.5 mole/l; time 15 min ; $HgCl_2$/AN=1/500

No	$HgCl_2$/NVC	Conversion (%)	M.W.
18	$1\cdot10^{-3}$	2.0	—
19	$3\cdot10^{-3}$	18.2	101 200
20	$5\cdot10^{-3}$	62.0	41 300
21	$7\cdot10^{-3}$	71.5	18 600

Probably, the role of AN is only that of $HgCl_2$ solubilizer with the result of a homogeneous system ; this fact is also proved by the tests presented in Table 4.

The effect of AN results form the comparison between test 15 and 20 ; when the system is homogeneous the conversion increases. Molecular weights decrease and the yield increases with the $HgCl_2$ content as shown in Table 4.

In figure 3 are given typical conversion-time curves (dilatometric method) for the NVC polymerization by the $HgCl_2$-AN mixture. The rate constant of reaction is similar to that reported by Plesch.[7] This fact is another argument to say $HgCl_2$ is the effective catalyst of the process. $CdCl_2$ is not soluble in AN.

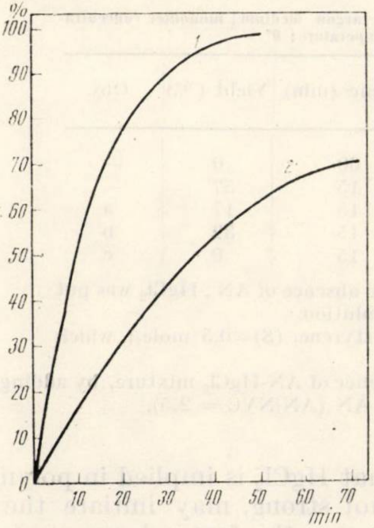

Fig. 3. — Conversion-time curves for NVC polymerization at 0°; [NVC]=0.5 mole/l; solvent, toluene; $[HgCl_2]/[AN]=1/500$;

1, $[HgCl_2]=2.5 mole/l \times 10^{-3}$; *2*, $[HgCl_2]=1.0 mole/l \times 10^{-3}$.

CONCLUSION

When $ZnCl_2$—AN complex was used, no alternate copolymerization occurred, probably due to a reaction rate of the pseudo-cationic polymerization of NVC greater than that of the copolymerization. This seems to be facilitated by the large cationic reactivity of NVC to the electron-donor nitrogen and the high stability of the cation, due to the conjugated carbazole ring.

Mercuric chloride does not form a stable complex with AN, but its solutions in AN may initiate the NVC polymerization, by a mechanism of cationic nature.

KINETIC DETERMINATION OF VANADIUM BY THE REACTION BETWEEN PYROGALLOL BROMINE RED AND POTASSIUM BROMATE

D. COSTACHE and S. SASU

University of Bucharest, Faculty of Chemistry
Chair of Analytical Chemistry and
State Committee of Planning
Bucharest, Romania

Received August 21, 1972

The reaction between pyrogallol bromine red and potassium bromate in acid medium, catalysed by vanadium ions, and the influence of the amounts of reagents, pH, wavelength and temperature on the reaction rate are investigated. A quantitative method for the determination of vanadium is given. The influence of other ions is studied and the main examined parameters are calculated.

The rate of a chemical reaction depends on the concentration of reagents, temperature, reaction medium (ionic strength, dielectric constant) and the presence of some substances called catalysts, as it results from the following reaction :

$$V = f\,(\text{conc., } t, \text{ medium, catalysts}) \qquad (1)$$

According to the classical definition of catalysts, these are substances, the presence of which, accelerates the reaction, and are again found complete at the end of the reaction. This definition can be accepted today only accompanied by the statement that their presence is active, and alters elementary processes.

The catalysts open new ways, energetically more advantageous, by means of some new transition stages, energetically poorer.

The action of the catalysts is selective in many cases, i. e. they increase the reaction rate of certain chemical processes. It is on these characteristics of the catalytic action that the determination of some ion traces is based. [1-9]

The present work investigate the reaction between pyrogallol bromine red and potassium bromate in acetic acid medium. The rate constants are calculated, the variation of these constants with the temperature is investigated, and the activation energies and pre-exponential factors are calculated.

On the basis of these studies an analytical method for the determination of vanadium traces in the range 6.16×10^{-10} gV/cm^3 – 6.16×10^{-9} gV/cm^3 is given.

EXPERIMENTAL

REAGENTS

Pyrogallol bromine red, concentration 5.20×10^{-4} g/cm^3 in ethyl alcohol.
Potassium bromide solution : 1.85×10^{-2} g/cm^3.
Reaction medium : acetic acid solution.
Vanadate solution : concentration 1.54×10^{-7} gV/cm^3
Bi-distilled water was used for all solutions.

PROCEDURE

The reaction mixture was prepared in 25 cm^3 flasks, in the following order : pyrogallol bromine red, acetic acid, potassium bromate and various amounts of ammonium vanadate. It is brought to the mark with twice distilled water. The timer is started and the flask content is stirred for 1 minute, then being passed into the spectrophotometer vat. Since after reaction the initially coloured solution decolorates, water is poured into the blind vat.

The concentrations of solutions in the vat are as follows

Pyrogallol bromine red	2.08×10^{-5} g/cm^3
Potassium bromate	7.40×10^{-4} g/cm^3
Vanadium ions	$6.16 \times 10^{-10} - 6.16 \times 10^{-9}$ gV/cm^3.

APPARATUS

The work was carried out with the horizontal Pulfrich Zeiss, Jena spectrophotometer and V.S.U.-1, and the wavelengths at which the method was set up, was $\lambda = 533$ nm.

DISCUSSIONS

The kinetic study of the reaction between pyrogallol bromine red and potassium bromate led to the conclusion that the reaction rate does not change with the time, which shows that we are dealing with an order zero reaction.

The expression of the rate in this case is :

$$-\frac{\mathrm{d}(a-x)}{\mathrm{d}t}=k \tag{2}$$

If we take into account the fact that the reaction takes place even in the absence of vanadium ions, but at a low rate, the expression of the rate should be written as follows :

$$-\frac{{}^{\mathrm{d}C}\text{pyrogallol bromine red}}{\mathrm{d}t}=k'C\text{ pyrogallol bromine red}=kCk^{C}\text{ pyrogallol bromine red}+k_c\cdot C_v\cdot C\text{ pyrogallol bromine red} \tag{3}$$

where :

k' = global rate constant
k = rate constant for the non-catalysed reaction
k_c = catalyst contribution to the increase of the rate reaction
C = pyrogallol bromine red = the reagent concentration
C_v = vanadium concentration.

Table 1 gives the values of the global rate constants for various catalyst concentrations.

Table 1

Values of the rate constants k for various concentrations of the catalyst

Conc. of V ($\mathrm{g/cm^3} \times 10^{-9}$)	$k \times 10^{-2}$ ($\mathrm{mol \cdot min^{-1}}$)
—	0.36
0.61	0.85
1.23	1.16
1.85	1.80
2.46	2.25
3.08	2.70
3.69	3.10
4.31	3.60
4.93	4.00
5.54	4.50
6.16	5.20

As it results from relation (1) the reaction rate is function of the reagent concentration, visible chiefly for the variation of the oxidant concentration ($KBrO_3$). Figure 1 shows the influence of the concentration of potassium bromate on the reaction rate.

By ΔD we have denoted the differences between the optical densities read after 10 and 12 minutes of the samples to which other amounts of bromates are added, the concentrations of other components being constant.

The figure shows that the reaction rate increases with the potassium bromate concentration and presents a relative stability in the concentration range $3.70 \times 10^{-4} - 14.80 \times 10^{-4}$ g $KBrO_3/cm^3$.

The reaction medium greatly influences the reaction rate.

If hydrochloric acid is used in the reaction, the reaction rate differs for each concentration of the acid, no matter how slightly this changes.

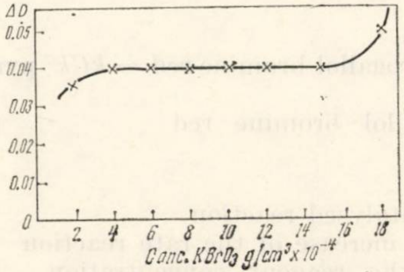

Fig. 1. — Influence of $KBrO_3$ concentration on the reaction rate.

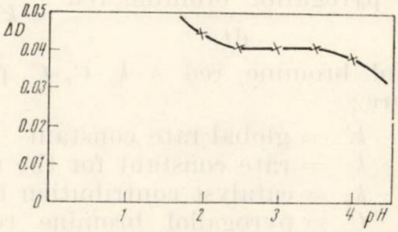

Fig. 2. — Influence of pH on the reaction rate.

If acetic acid is used there exists a range where the reaction rate remains constant. This range lies within pH 2.5—3.5, as may be observed from figure 2.

From relation (1) it also results that the reaction rate is influenced by the temperature. This influence is shown in table 2. The values of the rate constants are those corresponding to the catalytic reaction with vanadium concentration in the sample of 1.23×10^{-9} gV/cm³.

Table 2

Values of the rate constant k K, *vs* temperature (catalyst conc. 1.23×10^{-9} g/cm³)

$T°$	288	293	298	303	308
$k \times 10^{-2}$ ($mol \cdot min^{-1}$)	0.90	1.16	1.70	2.50	3.90
$\log k$	−2.055	−1.935	−1.770	−1.602	−1.409
$1/T \times 10^{-3}$	3.47	3.41	3.38	3.30	3.24

Figure 3 shows the values of the optical density *vs* the vanadium concentration. It should be noted that the readings after 10 and 12 minutes are listed. For the calibration graph we took into account the values read at minute 12.

Further on, the influence of alien ions was investigated. We have concluded that the determination of vanadium by the kinetic method, by means of the reaction between pyrogallol bromine red and potassium bromate in acetic acid medium, is disturbed by the Fe^{2+} and Fe^{3+} ions if the

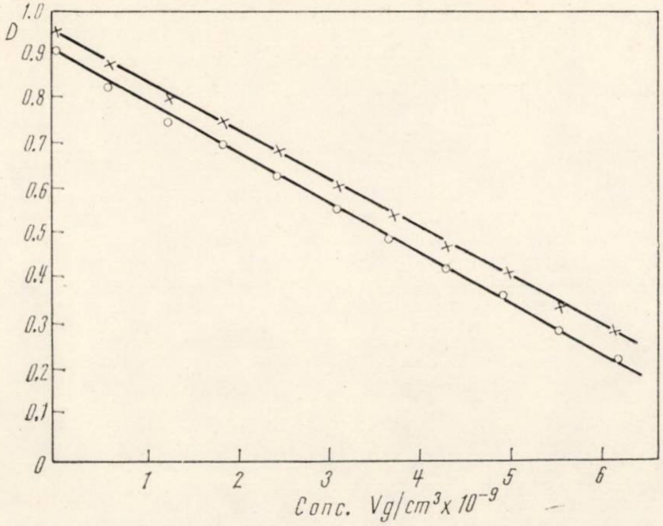

Fig. 3. — Variation in time of the D value.

ratios Fe^{2+}/V^{5+} and Fe^{3+}/V^{5+} exceed the value 100 : 1 and if the ratio Ti^{4+}/V^{5+} exceeds 1000 :1.

Table 3 shows a statistical processing of the results. The dispersions of selection around the points, the dispersions of selection around the calibration line and the range of dispersion are calculated.

Table 3

Main parameters of the statistical processing

Conc. of V g/cm³ × 10⁻⁹	$\bar{D}_{exp}$	$\bar{D}_{calcd}$	s^2 point 10^{-4}	A_0	A_1	$s^2 \times 10^{-4}$	$2ts$
0.61	0.811	0.819	5.434				
1.23	0.735	0.751	5.513				
1.85	0.692	0.683	8.300				
2.46	0.610	0.616	6.150				
3.08	0.539	0.547	5.147				
3.69	0.458	0.480	11.297				
4.31	0.401	0.412	9.989				
4.93	0.345	0.344	7.842				
5.54	0.274	0.277	5.626				
6.16	0.209	0.209	9.065				
				0.886	−0.110	10.96	0.284

To conclude we may say that with the aid of this method, vanadium can be determined in the range of concentrations between 6.16×10^{-10} gV/cm³ and 6.16×10^{-9} gV/cm³.

ORSZÁGOS MŰSZAKI KÖNYVTÁR ÉS DOKUMENTÁCIÓS KÖZPONT 1883

NOTE POUR LES AUTEURS

La *Revue Roumaine de Chimie* publie des articles en anglais, français, russe, allemand ou espagnol. Les auteurs sont priés d'envoyer des articles, notes, communications et comptes rendus inédits.

Les manuscrits seront dactylographiés à deux intervalles. Les tableaux seront dactylographiés sur feuilles séparées, de même que la légende des figures. Les diagrammes seront tracés à l'encre de Chine sur papier calque. Les tableaux et les figures seront numérotés par des chiffres arabes, en nombre strictement nécessaire. Prière de ne pas inscrire les mêmes données dans les tableaux et les figures. Les formules chimiques seront incluses dans le texte ; en outre, elles seront transcrites sur des feuilles séparées. Les auteurs sont priés d'indiquer les caractères italiques (en soulignant les lettres au crayon), ainsi que tout autre caractère spécial. L'ordre des références bibliographiques sera celui de leur mention dans le texte ; le nom de l'auteur sera précédé de l'initiale du prénom ; les publications périodiques seront présentées suivant les prescriptions internationales. Les références seront ajoutées à la fin de l'article ; elles paraîtront comme des notes, au bas de la page. Le texte sera précédé d'un résumé, comprenant 15 lignes au maximum.

L'entière responsabilité du contenu des articles appartient aux auteurs. On publie des articles dus aux collaborateurs roumains ou étrangers. Les auteurs recevront 50 tirés à part.

A PERTURBATION TREATMENT OF MOLECULAR COMPLEXES. III.[1]

IODINE COMPLEXES WITH FIVE-MEMBERED HETEROAROMATICS

MARIANA DOBRESCU-CIUREANU and V. E. SAHINI
Physical Chemistry Laboratory, University of Bucharest,
Bd. Republicii 13, Romania

Received December 28, 1972

A perturbation treatment described in a previous paper [1a] is applied to give a quantum mechanical description of the electronic structure of molecular complexes formed by iodine with several five-membered heteroaromatic molecules. The stable geometrical configuration of the complexes in the ground state is predicted by means of the stabilization energies calculated for various relative orientations between the donor and the acceptor. The charge distributions changes occurring by complex formation and the dipole moments of the complexes are calculated and discussed. The CT spectra are calculated and compared with the experimental data.

INTRODUCTION

The electronic structure of molecular complexes has already been the subject of numerous theoretical treatments aiming at constructing a satisfactory model which would describe their ground and excited state properties.[1–11] There are, however, some problems still open, which claim for further study :

a) the relative contributions of polarization and charge transfer in determining the ground state properties: stabilization energy, dipole moment, infrared spectra, etc.;

b) The possibility to calculate the energy contour maps and thus to predict the equilibrium geometrical configuration of a complex;

c) the evaluation of the charge displacements occurring both in the donor and the acceptor by reciprocal polarization and electron transfer;

d) the assignment of CT transitions and their relationship with the molecular structure of the parent molecules.

Our purpose was to examine these points in the particular case of complexes formed by pyrrole, furan and thiophene with iodine, applying a perturbation treatment described in a previous paper.[1a]

These complexes were already experimentally studied by Lang.[12]

On the basis of his results it seems to be clear that these complexes are of the $\pi-\sigma$ type, that is, the donor action is spread over the π electronic system of the heteroaromatic molecule.

1. METHOD OF CALCULATION

The general features of the present treatment are those presented in paper I.[1a] The SCF MO's for the heterocyclic molecules, used as a starting point in our calculation, were those calculated by Solony, Birss and Greenshields.[13]

As all complexes were considered to be of a $\pi-\sigma$ type, we assumed in all cases a model which allowed the $5p\sigma$ orbitals of iodine molecule to overlap with the donor's $2p\pi$ orbitals.

In calculating the energy contour maps, a great number of geometrical configurations were taken into account under the following limitations:

a) The halogen molecule was kept at right angles to the plane of the heterocyclic ring.

b) The donor-acceptor distance was 3.5 Å in all cases.*

We considered that only the $5p\sigma_u$ and $5p\sigma_g$, from the valence orbitals of the iodine molecule, participated in forming the molecular complex. Thus, the charge transfer takes place from the occupied π orbitals of the heterocycle to the strongly antibonding $5p\sigma_u$ orbital of the iodine molecule.

Choice of parameters. In calculating the energy of the CT states we used the vertical ionization potentials of the heterocyclic molecules, experimentally determined from electron impact data.[14]

$$I_p^{\text{pyrrole}} = 8.20 \text{ eV} : I_p^{\text{furan}} = 8.89 \text{ eV} \quad I_p^{\text{thiophene}} = 8.99 \text{ eV}$$

* This is the value experimentally determined for benzene-I_2.

---

[12] J. P. Lang, *J. Amer. Chem. Soc.*, **84**, 4438 (1962).

[13] N. Solony, F. W. Birss and J. B. Greenshields, *Canad, J. Chem.*, **43**, 1569 (1965).

[14] a) R. W. Kiser "Introduction to Mass Spectrometry and its Applications",Prentice Hall, Inc., 1965; b) K. Watanabe and T. Naguyama, *J. Chem. Phys.*, **29**, 48 (1958); c) W. C. Price and A. D. Walsh, *Quart Rev.*, **2**, 73 (1948); *Proc. Roy. Soc. (London) Ser. A*, **179**, 201 (1941).

The upper ionization potentials were determined from these data by assuming that the difference between two ionization potentials is equal to the difference in the corresponding SCF orbital energies.

The electron affinity of the iodine molecule was taken to be 2 eV.[1b]

The semiempirical parameters used in our calculations were calculated as follows. The intermolecular resonance integrals $\beta_{\delta\rho}$ were calculated using Mullikans'formula

$$\beta_{\delta\rho} = \frac{1 + Scc}{1 + S_{\delta\rho}} \cdot \frac{S_{\delta\rho}}{Scc}\ \beta cc \tag{1}$$

$S_{\delta\rho}$ is the overlap integral between the atomic orbital φ_δ of the donor and the atomic orbital φ_ρ of the acceptor. In order to calculate these overlap integrals, the atomic orbitals of the basic system were decomposed into a σ and π part, as shown in fig. 1.

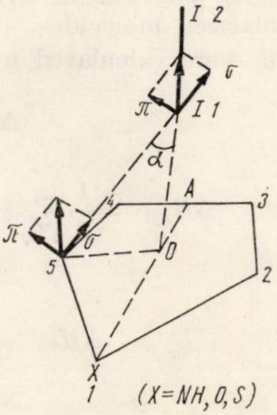

Fig. 1. — Iodine complexes with five-membered heteroaromatics.

Thus

$$S_{\delta\rho} = S^{\pi}_{\delta\rho} \sin^2 \alpha + S^{\sigma}_{\delta\rho} \cos^2 \alpha \tag{2}$$

The $S^{\pi}_{\delta\rho}$ and $S^{\sigma}_{\delta\rho}$ integrals were calculated according to Mulliken, Orloff and Orloff.[15] The $S^{\pi}_{\delta\rho}$ integrals have proved to be negligible, so that

$$S_{\delta\rho} \cong S^{\sigma}_{\delta\rho} \cos^2 \alpha \tag{3}$$

In order to simplify the calculation we made the assumption of formal neglect of differential overlap.

The bielectronic repulsion integrals $(\delta\delta/\rho\rho)$ were calculated using Klopmans' formula.[16]

2. RESULTS AND DISCUSSIONS

2.1. STABILIZATION ENERGY

The stabilization energy of a donor-acceptor complex can be partitioned in several parts

$$\Delta H = \Delta H_{\text{coul}} + \Delta H_{\text{pol}} + \Delta H_{\text{CT}} + \Delta H_{\text{CT pol}} + \dots$$

In this formula ΔH_{coul} and ΔH_{pol} are due to the Coulomb- and polarization-type electrostatic interactions between the donor and the acceptor; ΔH_{CT} is due to the intermolecular resonance, therefore to the interaction between the ground and CT states. The last term, which was called "the charge transfer polarization term" appears because the resonance occurs between polarized molecules.

These terms were calculated as follows

$$\Delta H_{\text{coul}} = 0 \tag{4}$$

$$\Delta H_{\text{pol}} = \frac{1}{2} \sum_{\delta < \varphi} \left[\pi_{\rho\rho} \, (\Delta\alpha_\rho)^2 + 2\pi_{\rho\varphi} \, \Delta\alpha_\rho \, \Delta\alpha_\varphi\right] \tag{5}$$

$$\Delta H_{\text{CT}} = \sum_{i_d}^{\text{occ}} \frac{\left(\sum\limits_{\delta,\rho} c^{\delta}_{i_d} \, c^{\rho}_{j'_a} \, \beta_{\delta\rho}\right)^2}{E_{N_0} - E_{E, id \to j'_a}} \tag{6}$$

$$\Delta H_{\text{CT pol}} = \sum_{i_d}^{\text{occ}} \frac{\left\{\sum\limits_{\delta,\rho} 2\sqrt{2}\left[\sqrt{2}\,\eta^{E_n}_{l_d \to i_d} \, c^{\delta}_{l_d} \, c^{\rho}_{j'_a} + \xi^{N_0}_{j_a \to j'_a} \, c^{\delta}_{i_d} \, c^{\rho}_{j_a}\right] \beta_{\delta\rho}\right\} \sum\limits_{\delta,\rho} c^{\delta}_{i_d} \, c^{\rho}_{j'_a} \, \beta_{\delta\rho}}{E_{N_0} - E_{E, id \to j'_a}} \tag{7}$$

An important problem to be solved is to determine the stable geometrical configuration of the complex in the ground state; to do that, stabilization energies were calculated for a great number of geometrical configurations; the energy contour map was obtained by plotting the stabilization energies against the position of the I—I bond projection in the plane of the heterocycle (O). All complexes show an energy minimum located in the symmetry plane of the ring. As an example, the energy contour map of pyrrole—I_2 is presented in fig. 2. The stable geometrical structures predicted by the present theoretical considerations are presented in table 1.

Another point to solve is to establish the relative importance of Coulomb, CT, polarization and CT polarization terms in determining the stability of the complexes.

The results calculated by (4)–(7) for the equilibrium configuration of the three complexes are presented in table 2 together with those previously obtained for some molecular complexes of aromatic hydrocarbons.[1b]

Table 1

Predicted equilibrium geometrical configuration for iodine complexes with five-membered heteroaromatics

Donor	OX (Å)	OA (Å)
pyrrole	1.7	0.42
furan	1.8	0.33
thiophene	1.4	0.62

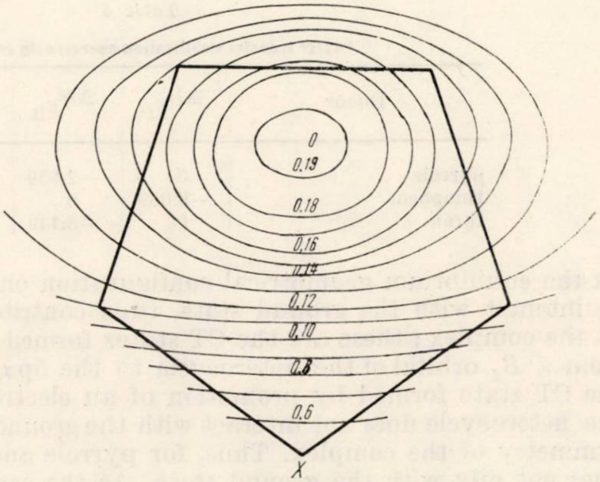

Fig. 2. – The energy contour map of pyrrole-I_2 complex (the energies are expressed in eV).

Table 2

Stabilization energies of iodine complexes with aromatic and heteroaromatic donors (in *k*cal/mol)

Donor	ΔH_{coul}	ΔH_{pol}	ΔH_{CT}	$\Delta H_{CT\ pol}$	ΔH_{tot}
pyrrole	0	−0.0004	−4.377	+0.050	−4.327
thiophene	0	−0.0001	−3.972	+0.001	−3.971
furan	0	−0.0003	−3.804	+0.036	−3.768
benzene	0	0	−4.78	0	−4.78
naphthalene	0	0	−4.39	−0.48	−4.87
phenanthrene	0	0	−4.75	−0.15	−4.90

As shown in table 2 the Coulomb term is zero in all cases, whereas the polarization term is zero only for hydrocarbon complexes; in the case of the complexes formed by iodine with five membered heteroaromatics this term is different from zero, but negligibly small, and thus it plays no role in determining the binding energy. The main contribution to the complex stabilization is given in all cases by the CT term *. $\Delta H_{\mathrm{CT\ pol}}$ takes small (but not negligible), positive or negative values (see for example the naphthalene-I_2 complex); thus, this term has to be taken into account in a complete evaluation of the stabilization energy. According to the data presented here, we are able to predict the following order of the terms contributing to the binding energy of a molecular complex :

$$\Delta H_{\mathrm{CT}} \gg \Delta H_{\mathrm{CT\ pol}} \gg \Delta H_{\mathrm{pol}}$$

The contribution of the three CT states to the binding energy of the complex is shown in table 3.

Table 3

Charge transfer stabilization energies (in kcal/mol)

Donor	$\Delta H_{E_{\mathrm{I}}}$	$\Delta H_{E_{\mathrm{II}}}$	$\Delta H_{E_{\mathrm{III}}}$	ΔH_{CT}
pyrrole	0	−2.659	−1.718	−4.377
thiophene	−0.039	0	−3.933	−3.972
furan	0	−3.149	−0.655	−3.804

In the equilibrium geometrical configuration only two CT states are able to interact with the ground state, thus contributing to the stabilization of the complex; these are the CT states formed by promoting an electron from a B_2 orbital of the heterocycle to the $5p\sigma_u$ orbital of the complex; the CT state formed by promotion of an electron from the A_2 orbital of the heterocycle does not interact with the ground state owing to the overall symmetry of the complex. Thus, for pyrrole and furan the first CT state does not mix with the ground state. As the same thing happened in the case of halogen-aromatic hydrocarbon complexes (except for phenanthrene-I_2), we can infer that there is generally no direct correlation between the stabilization energy and the ionization potential of the donor.

As shown in table 3, the contributions of the two CT states are generally of a comparable order of magnitude. Thus, it should be noted that all CT states should be taken into account in calculating the stabilization energy of a complex, not only the lower ones.

2.2. THE CHARGE DISPLACEMENTS AND DIPOLE MOMENTS

The charge densities of the donor atoms, in the ground state of the complex, can be expressed as :

$$q_{\delta}^{\mathfrak{N}_0} = \frac{1}{1 + a_{E_1}^2 + a_{E_2}^2}\left[p_{\delta\delta}^{N_0} + a_{E_1}^2 p_{\delta\delta}^{E_1} + a_{E_2}^2 p_{\delta\delta}^{E_2} + 2a_{E_1} a_{E_2} c_{i_d}^{\delta} c_{l_d}^{\delta}\right] \qquad (8)$$

---

* This is why, in calculating the energy contour maps we took into consideration only the CT stabilization energy.

where the two CT states interacting with the ground state were noted by E_1 and E_2; these states occurred by the promotion of an electron from the occupied MO's of the donor (φ_{i_d} and φ_{i_d} respectively) to the empty one of the acceptor ($\varphi_{j_a'}$). The $p_{\delta\delta}^{E_1}$ and $p_{\delta\delta}^{E_2}$ were calculated according to eqs. (43)—(44) of part I.[1a]

The charge densities of the acceptor atoms are calculated following the formula

$$q_\rho^{\mathcal{N}_0} = \frac{1}{1 + a_{E_1}^2 + a_{E_2}^2} \left[p_{\rho\rho}^{N_0} + a_{E_1}^2 \, p_{\rho\rho}^{E_1} + a_{E_2}^2 \, p_{\rho\rho}^{E_2}\right] \tag{9}$$

In calculating $q_\delta^{N_0}$ and $q_\rho^{N_0}$ we found out that a_{E_1} and a_{E_2} can be satisfactorily approximated as

$$a_{E_1} = \frac{H_{N_0 E_1}}{W_{N_0} - W_{E_1}} \cong \frac{\sqrt{2} \sum\limits_{\delta,\rho} c_{i_d}^{\delta} \, c_{j_a'}^{\rho} \, \beta_{\delta\rho}}{W_{N_0} - W_{E_1}} \equiv a_1 \tag{10}$$

$$a_{E_2} = \frac{H_{N_0 E_2}}{W_{N_0} - W_{E_2}} \cong \frac{\sqrt{2} \sum\limits_{\delta,\rho} c_{i_d}^{\delta} \, c_{j_a'}^{\rho} \, \beta_{\delta\rho}}{W_{N_0} - W_{E_2}} \equiv a_2 \tag{11}$$

Thus, $\Delta q_{\rho,\delta} = q_{\delta,\rho}^{\mathcal{N}_0} - q_{\delta,\rho}$ can be partitioned in the following form

$$\Delta q = \Delta q^{\mathrm{CT}} + \Delta q^{\mathrm{pol}} + \Delta q^{\mathrm{CT\,pol}} \tag{12}$$

The terms in (12) were calculated for the acceptor atoms using the formulae

$$\Delta q_\rho^{\mathrm{CT}} = \frac{(a_1^2 + a_2^2)\,(c_{j_a'}^{\rho})^2}{1 + a_1^2 + a_2^2} \tag{13}$$

$$\Delta q_\rho^{\mathrm{pol}} = \frac{2\sqrt{2}}{1 + a_1^2 + a_2^2} \, \xi_{j_a \to j_a'}^{N_0} \, c_{j_a}^{\rho} \, c_{j_a'}^{\rho} \tag{14}$$

$$\Delta q_\rho^{\mathrm{CT\,pol}} = \frac{2\,(a_1^2 + a_2^2)}{1 + a_1^2 + a_2^2} \, \xi_{j_a \to j_a'}^{E_1, E_2} \, c_{j_a}^{\rho} \, c_{j_a'}^{\rho} \tag{15}$$

The results obtained using these formulae are presented in table 4 together with the total amount of charge transfer.

$$\Delta Q = \sum_\rho \Delta q_\rho = - \sum_\delta \Delta q_\delta \tag{16}$$

As seen from table 4, the main contribution to Δq_{N_0} is given by Δq^{CT}. The Δq^{pol} and $\Delta q^{\mathrm{CTpol}}$ have small, positive or negative values, thus determining the polarization of the halogen molecule.

Table 4

Amount of charge transferred to the acceptor atoms in the ground state of the complex (in − e units)

Donor	ρ	$\Delta q_\rho^{\mathrm{CT}}$	$\Delta q_\rho^{\mathrm{pol}}$	$\Delta q_\rho^{\mathrm{CTpol}}$	Δq_ρ	ΔQ
pyrrole	1	+0.0202	−0.0016	+0.0033	+0.0219	0.0404
	2	+0.0202	+0.0016	−0.0033	+0.0185	
furan	1	+0.0145	−0.0008	+0.0024	+0.0161	0.0290
	2	+0.0145	+0.0008	−0.0024	+0.0129	
thiophene	1	+0.0124	−0.0013	+0.0023	+0.0134	0.0248
	2	+0.0124	+0.0013	−0.0023	+0.0114	

Similar formulae were derived to calculate the Δq_δ for the donor atoms. As in all cases $\Delta q_\delta^{\mathrm{pol}}$ are zero and $\Delta q_\delta^{\mathrm{CTpol}}$ are negligibly small, the only significant contribution to be considered was Δq^{CT}

$$\Delta q_\delta^{\mathrm{CT}} = -\frac{(a_1\, c_{i_d}^{\delta} - a_2\, c_{i_d}^{\delta})^2}{1 + a_1^2 + a_2^2} \tag{17}$$

The charge distribution changes after complexing are presented in fig. 3; they can be discussed in terms of the electronic structure of the donor molecules. In fact, one can observe a gradual diminution of the heteroatom capacity to donate electrons to aromatic conjugation in the pyrrole-furan-thiophene series. For iodine complexes formed by these donors one can note several changes occurring in the same order:

b)

Fig. 3. — Charge densities of uncomplexed donors (*a*) and charge displacements occurring by complex formation (*b*) (in − e units).

a) The gradual diminution of the heteroatom donor power and the enhancement of the donating capacity of the positions 2,5 and 3,4. As seen from fig. 3, in pyrrole-I_2 almost the whole positive charge due to complex formation is located on nitrogen, whereas in furan-I_2 this charge is distributed between oxygen and the C_3-C_4 positions. In thiophene-I_2 complex the charge transfer occurs predominantly from the C_2-C_5 and C_3-C_4 positions.

These charge displacements are in accordance with the predicted changes in the geometry of the complex.

b) The lowering of the total amount of charge transfer.

c) The gradual diminution of iodine molecule polarization.

The dipole moments of these complexes can be expressed as

$$\vec{\mu}^{\text{complex}} = \vec{\mu}^{\circ} + \vec{\mu}^{\text{CT}} + \vec{\mu}^{\text{pol}} + \vec{\mu}^{\text{CT pol}} \tag{18}$$

A comment should be made with respect to $\vec{\mu}^{\text{CT}}$. $\vec{\mu}^{\text{CT}}$ is obtained as a vectorial sum of two components

$$\vec{\mu}^{\text{CT}} = \vec{\mu}_{\parallel}^{\text{CT}} + \vec{\mu}_{\perp}^{\text{CT}}$$

where the subscripts indicate the orientation to the ring plane, $\vec{\mu}_{\parallel}^{\text{CT}}$ can be either parallel or antiparallel to the the permanent dipole moment $\vec{\mu}_0$. As seen from table 5, in the case of pyrrole-I_2 and thiophene-I_2 complexes, $\vec{\mu}_{\parallel}^{\text{CT}}$ is parallel, whereas for furan-I_2 $\vec{\mu}_{\parallel}^{\text{CT}}$ is antiparallel to $\vec{\mu}^{\circ}$. Thus, for the latter, $\vec{\mu}_{\parallel}^{\text{CT}}$ causes a lowering of the in-plane dipole moment μ° * The results are presented in table 5.

Table 5

Calculated dipole moments in the ground state* (in Debye)

Donor	$\mu^{\circ 19}$	$\mu_{\parallel}^{*\text{CT}}$	$\mu_{\perp}=\mu_{\perp}^{\text{CT}}+\mu^{\text{pol}}+\mu^{\text{CTpol}}$	μ^{complex}
pyrrole	1.8 ↓	0.254 ↓	0.915	2.27
furan	0.7 ↑	0.115 ↓	0.652	0.87
thiophene	0.56 ↑	0.017 ↑	0.564	0.80

* The arrows indicate the orientation of the in-plane dipole moments against the heteroatom.

2.3. CHARGE TRANSFER SPECTRA

The CT spectra calculated for the three complexes are presented in table 6 together with the experimental data.

---

* We suppose that in other cases this lowering might be large enough to determine a diminution of the overall moment of the complex compared with the moment of the parent molecule (For example the dipole moment of uncomplexed nitrobenzene is 4.22 D, whereas it is 3.73 D for the naphthalene complex). Such cases were considered so far to be a proof of the determining role of polarization forces.[17,18]

[17] M. J. Mantione *Theor. Chim. Acta,* **11,** 119 (1968).

[18] J. P. Malrieu and P. Claverie, *J. chim. phys,* **65,** 735 (1968).

[18] H. Kofod, L. E. Sutton and J. Jackson, *J. Chem. Soc.,* **1952,** 1476.

For pyrrole and furan complexes the theory predicts the existence of two CT bands, which are in agreement with the experimental ones. For thiophene-I_2 complex the theory predicts two superimposed bands, whereas the experiment reveals the existence of a single large CT band. We suppose that the observed band is due to a superposition of the first two CT transitions, a fact which is supported by the broadening of this band *.

Table 6

Experimental and calculated CT spectra

Donor	$\lambda_{\text{calc (nm)}}$	$\lambda^{12}_{\text{exp (nm)}}$
pyrrole	360.3	360
	318.7	285
furan	301.8	317
	233.2	240
thiophene	289.5	295 large
	289.0	

It should be noticed that, both for pyrrole and furan complexes, the first CT state, which is responsible for the apearance of the first CT band, does not interact with the ground state. Thus, ground state properties like : dipole moment, infrared spectra and stabilization energy should not be related to the CT transition energy. This idea is supported by our previous results on halogen-aromatic hydrocarbon complexes.[1b]

* This idea was also formulated by Lang.[12]

Revue Roumaine de Chimie, 18, 6, 931–943 (1973)

THE ELECTRONIC STRUCTURE OF SOME LADDER POLYMERS. I

BAND STRUCTURE OF POLYACENES AND NITROGEN SUBSTITUTED POLYACENES

PETER G. PERKINS

Department of Pure and Applied Chemistry,
University of Strathclyde, Glasgow C. 1., Scotland

Received January 15, 1973

The fused ring polyacene, polypyrazine, and polypyridine have been studied by the extended Hückel tight bonding solid state method. It is found that some band overlap occurs between valence σ and conduction π^* bands but the density of states in these regions are not high enough to confer metallic conductivity. Moreover the direct band gap at $k = \pi/a$ is, in effect, increased by the low density of states at the top of the π valence band.

There is presently considerable interest in the electrical properties of organic polymers related to the polyacenes (Figure 1*a*). Recent experimental studies on paracyanogen [1] ('polypyrazine') (Figure 1*b*), directed towards determining the valence-conduction band gap for this material and comparing its semi-conducting properties with those of the related polyacenes,[2] have shown that substitution of two nitrogen atoms for two carbons in each unit of the structure only marginally increases the band gap ΔE.

In order to throw light on these findings, to ascertain to what extent the polypyridine structure (Figure 1*c*) are related electronically, and to try and rationalise other aspects of the electronic behaviour of the series of compounds*, we have calculated the electronic band structures in the solid state of several series of these compounds. In the cases chosen, the approach which has been adopted is that of the extended Hückel procedure, couched in the solid-state formalism, and including all valence orbitals (both σ and π type) in the basis set. This treatment was carried through so as to ascertain the ordering of the bands, and their character, on both sides of the valence-conduction energy gap. As a consequence we are able to reveal the important features of the energy spectrum (*i, e.* the bands near the gap) and in future work will examine the states more closely and in a more sophisticated manner. This is important because until recently it has been assumed that planar molecules, on which the polymers are based, have energy level patterns in which π type orbitals alone are juxtaposed to the bonding-antibonding energy gap. However, theoretical work [3] on several such molecules (*e.g.* on ethylene) has shown this supposition to be untrue and there are a number of levels of σ symmetry in this energy region. That this was not known until recently is not surprising since their existence is not readily shown up by experiment : in general, optical excitations from, or to, σ levels are either forbidden or only weakly polarised out of the molecular plane. Hence one of the problems we tackle here is to establish how the σ and π levels are situated with respect to the wave vector k in the $E(k)$ *vs* k diagram.

* For example, only polyacenes with up to seven rings in the molecule are known[2] and hence there must be some uncertainty with respect to the degree of polymerisation of materials such as paracyanogen.

CALCULATIONAL METHOD

EXTENDED HÜCKEL THEORY FOR THE SOLID STATE

We write a crystal wave function thus,

$$\Psi_i(k) = \sum_{r=1}^{n} c_{ir}(k)\, b_r(k)$$

where $b_r(k)$ is a Bloch wave function

$$b_r(k) = \frac{1}{\sqrt{N}} \sum_{R_i(i=1)}^{N} e^{ikR_i}\, a_r(R - R_i)$$

---

[3] M. B. Robin and R. R. Hart, *Theoret. chim. Acta*, **3**, 375 (1965) ; *ibid.* and N. A. Kuebler, *J. Chem. Phys.*, **44**, 1803 (1966).

k is the wave vector and $a_r(R - R_i)$ is an atomic orbital situated at a vector distance R_i from the origin.

Use of the one-electron crystal wave functions leads to the problem of solving the set of simultaneous equations

$$\sum_{r=1}^{n} c_{ir}(k)\,[\mathrm{H}_{sr} - E_i(k)\,S_{sr}(k)] = 0$$

where

$$\mathrm{H}_{sr} = < b_s(k)^* \,|\mathrm{H}|\, b_r(k) >$$

and

$$S_{sr} = < b_s(k)^* \,|\, b_r(k) >$$

These equations may be considered in determinantal form in the usual way, thus

$$\begin{vmatrix} \mathrm{H}_{11} - E\mathrm{S}_{11} & \mathrm{H}_{12} - E\mathrm{S}_{12} \ldots\ldots \\ \mathrm{H}_{21} - E\mathrm{S}_{21} & \mathrm{H}_{22} - E\mathrm{S}_{22} \ldots\ldots \\ \cdot & \\ \cdot & \\ \cdot & \\ \cdot & \\ \mathrm{H}_{n1} - E\mathrm{S}_{n1} \ldots & \mathrm{H}_{nn} - E\mathrm{S}_{nn} \end{vmatrix} = 0$$

The fact that $\mathrm{S}_{ii} \neq 0$ is troublesome. Unlike Hückel theory for molecules (where $\mathrm{H}_{rr} = \alpha$) the diagonal element H_{rr} is represented.

$$\mathrm{H}_{rr} = < b_r(k)^* \,|\mathrm{H}|\, b_r(k) >$$

In expanding this term all non-neighbour interactions are neglected. There are N cases where $i = j$, *i.e.*, $R_i - R_j = 0$. We refer to these $\mathrm{H}_{rr}(R_0)$. Similarly, there are N terms where $a_r(R - R_i)$ and $a_r(R - R_j)$ are functions situated on neighbouring atoms, *i.e.*, $R_i - R_j = R_1$, and a further N terms where $R_i - R_j = -R_1$. These are designated R_1 and R_{-1} respectively. Hence, we have

$$\mathrm{H}_{rr}(R_0) = < a_r(R_0)^* \,|\mathrm{H}|\, a_r(R_0) > = -I_r$$

$$\mathrm{H}_{rr}(R_1) = \mathrm{e}^{ik\cdot R_1} < a_r(R_0)^* \,|\mathrm{H}|\, a_r(R_1) >$$

I_r is the valence state ionisation potential $< a_r(R_0) \,|\mathrm{H}|\, a_r(R_1) >$ represents the interaction energy of orbitals a_r in neighbouring unit cells.

These terms may be evaluated by the Mulliken-Wolfsberg-Helmholtz expression [4]

$$< a_r (R_0)^* |\mathrm{H}| a_r (R_1) > = 0.5 \times A \times S_{rr} (R_1) [-I_r + (-I_r)]$$

A is constant which is generally given a value between 1.0 and 2.0 (see later). $S_{rr}(R_1)$ is the usual interorbital overlap integral. Now, $\mathrm{H}_{rr}(R_{-1})$ may be evaluated by substituting R_{-1} for R_1 in the expression for $\mathrm{H}_{rr}(R_1)$.

Hence we have,

$$\mathrm{H}_{rr} (R_1) = \mathrm{e}^{ik \cdot R_1} \times A \times 0.5 \times S_{rr} (R_1) [-2\mathrm{I}_r]$$

$\mathrm{H}_{rr} (R_{-1})$ is obtained by substituting R_{-1} for R_1

Thus,

$$\mathrm{H}_{rr} = -I_r + 2 \cos (k \cdot R_1) \times A \times S_{rr} (R_1) [-I_r]$$

The H_{rr} may thus be calculated for any particular value of k.

The off-diagonal elements H_{sr} may now be derived in a similar way and is

$$\mathrm{H}_{rs} = \mathrm{H}_{rs} (R_0) + \cos (k \cdot R_1) [\mathrm{H}_{rs}(R_1) + \mathrm{H}_{rs} (R_{-1})] +$$
$$+ i \sin (k \cdot R_1) [\mathrm{H}_{rs} (R_1) - \mathrm{H}_{rs} R_{-1}]$$

Now, the determinant to be evaluated contains terms S_{ij}, which are not equal to zero, and so heavy transformations of the type

$$\begin{vmatrix} \mathrm{H}_{11} - E\mathrm{S}_{11} \cdot \cdot \cdot \cdot & \cdot \\ \mathrm{H}_{21} - E\mathrm{S}_{21} & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \\ \cdot \cdot \cdot \cdot & \mathrm{H}_{nn} - E\mathrm{S}_{nn} \end{vmatrix} \rightarrow \begin{vmatrix} \dfrac{\mathrm{H}_{11}}{\mathrm{S}_{11}} - E \cdot \cdot \cdot \cdot \cdot & \cdot \\ [\mathrm{S}_{11}\mathrm{S}_{22}]^{-1/2}\mathrm{H}_{21} - E\mathrm{S}_{21} & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \\ \cdot \cdot \cdot \cdot \cdot \cdot \cdot & \dfrac{\mathrm{H}_{nn}}{\mathrm{S}_{nn}} - \mathrm{E} \end{vmatrix} = 0$$

$$\mathrm{S}_{11} \neq 1, \; \mathrm{S}_{22} \neq 1 \; \ldots\ldots \; \mathrm{S}_{nn} \neq 1$$

---

[4] R. S. MULLIKEN, *J. Phys. Chem.*, **56**, 295 (1952); M. WOLFSBERG and L. HELMHOLTZ, *J. Chem. Phys.*, **20**, 837 (1952).

are required to bring it into a suitable form for diagonalisation of the corresponding matrix.[5] Moreover, the eigenvectors of the matrix must be back-transformed thus

$$(C_{kj,1}\ C_{kj,2} \cdots C_{kj,n}) \to (C'_{kj,1}\ C'_{kj,2} \cdots C'_{kj,n}) \left| \begin{array}{cccc} S_{11}^{-\frac{1}{2}} & 0 & \cdots & 0 \\ 0 & S_{22}^{-\frac{1}{2}} & & \\ \vdots & & \ddots & \\ 0 & \cdots & \cdots & S_{nn}^{-\frac{1}{2}} \end{array} \right|$$

A simple way out of this problem is found by setting the Bloch overlap integrals, $S_{ij} = \delta_{ij}$. This is in keeping with the zero differential overlap approximation and reduces the eigenvalue problem considerably.

In the present work the atomic parameters (α) were accorded the values given in Table 1.

Table 1

Hückel α parameters (eV)

Carbon	$2s$	-19.44
	$2p$	-10.67
Hydrogen		
	$1s$	-13.06
Nitrogen	$2s$	-25.58
	$2p$	-13.19

The elements $<a_r (R - R_i)^* \,|\mathrm{H}|\, a_r (R - R_j)>$ which occur in the Hückel matrix were obtained by the arithmetic Mulliken-Wolfsberg-Helmholtz expression.[4] Bond lengths were those for anthracene, pyridine, and pyrazine.[6]

RESULTS AND DISCUSSION

1. ENERGY BAND STRUCTURE

Figures 2—6 illustrate the $E(k)$ *vs* k curves for polyacene, polypyrazine, and polypyridine. In the first two cases two separate values for A (1.0 and 2.0) were used in the series of calculations. This was done so as to check the sensitivity of the results of the calculation in the important regions (*e.g.*, around the band gap) so as to be sure that the conclusions drawn would not stem from artefacts of the calculational method. A full discussion of the effects of the change of this A factor, in the context of a more sophisticated method, has been given previously with regard to polyethylene [7] and, in that work, it was pointed out that the main changes in band structure due to the change of A occurs in the high-energy bands, whilst leaving the picture relatively unchanged around the band gap. It was further concluded that an A factor close to 2.0 is appropriate for calculations of this type. This has been confirmed by a comparison of Extended Hückel and CNDO-type calculations on the linear phosphite polymer. [8,9] Hence for polypyridine only one calculation, with $A = 2.0$ was performed.

Polyacene has 18 bands, polypyridine 17, and polypyrazine, 16, and so for clarity in figures 2—6 some of the electronic bands have been excluded: those remaining are restricted to featuring (*a*) the π bands, which are expected to be important in electron delocalisation phenomena and (*b*) the σ bands which border the band gap.

It is immediately obvious in all the systems that, contrary to the usual assumptions, π or π^* bands are not the only ones to border the band gap and the electronic properties depend somewhat on high lying σ and low lying σ^* levels. However what is important is that the pattern for $A = 1.0$ and $A = 2.0$ is similar in this region for the first two cases. We therefore assume that this situation will also obtain for polypyridine.

It is interesting and significant that, in all three cases, there is no real band gap and indirect overlap between the valence and conduction bands appears. (Table 2) The parallel with the situation in graphite,[10] where band overlap is also believed to occur, is quite marked.

In all cases the conduction bands are of π^* type and the width of these are also listed in Table 2.

Remarkably, the band gaps between the $\pi \rightarrow \pi^*$ bands are unaffected by changing A from 1.0 to 2.0 whilst both the band widths and the band overlaps are approximately doubled.
Another effect of A is to shift the position of the band gap in the energy scale. Because of the latter features, we do not really know what is the 'correct' A factor and so we should not take the calculated band widths

[10] C. A. Coulson, *Nature*, **159**, 265 (1941).

too seriously (although clearly they are broad). However, we may safely compare changes over the series of systems. It is interesting that, in all characteristics, both the polyacene and polypyrazine exhibit propensity to electron delocalisation which is greater than in polypyridine. However, because the conduction bands of all the systems are wide, the polypyridine

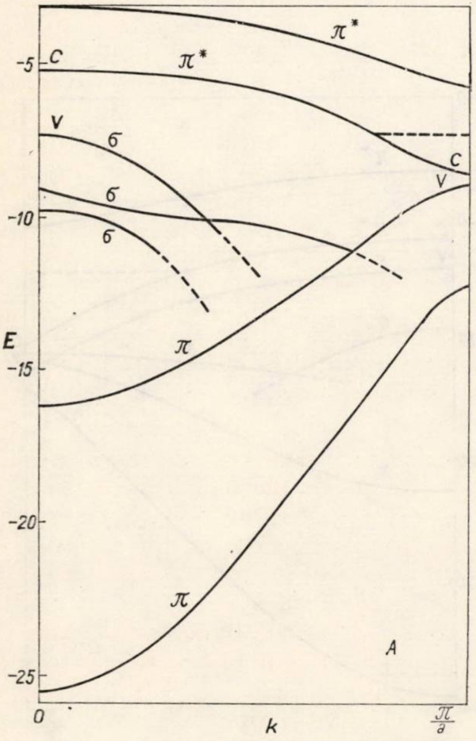

Fig. 2. — Band structure for polyacene $A = 1.0$.

Fig. 3 — Band structure for polyacene $A = 2.0$.

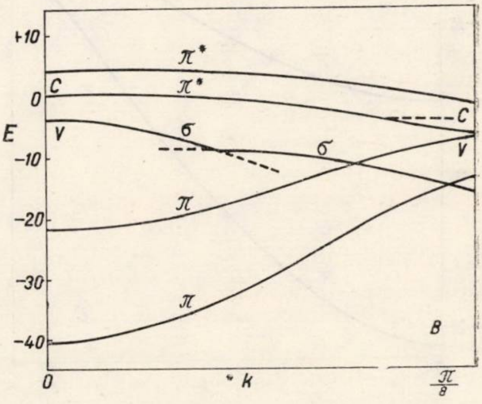

Table 2

Calculated Properties for Ladder Polymers (eV)

	Polyacene		Polypyrazine		Polypyridine
	$A = 1.0$	$A = 2.0$	$A = 1.0$	$A = 2.0$	$A = 2.0$
$\pi - \pi^*$ band gap	0.3	0.3	1.0	1.0	4.1
$\pi^* - \sigma$ band overlap	1.2	2.7	2.5	6.0	1.7
π^* band width	3.3	6.8	4.0	8.5	5.7
π band width	16.8	33.5	14.8	28.4	28.2

should not be a poorer conductor of electricity. Experimentally, polyacrylonitrile has been found [11] to exhibit a conductivity which varies with the degree of further heat treatment of the material but which, in all cases, is symptomatic of a good electrical conductor.

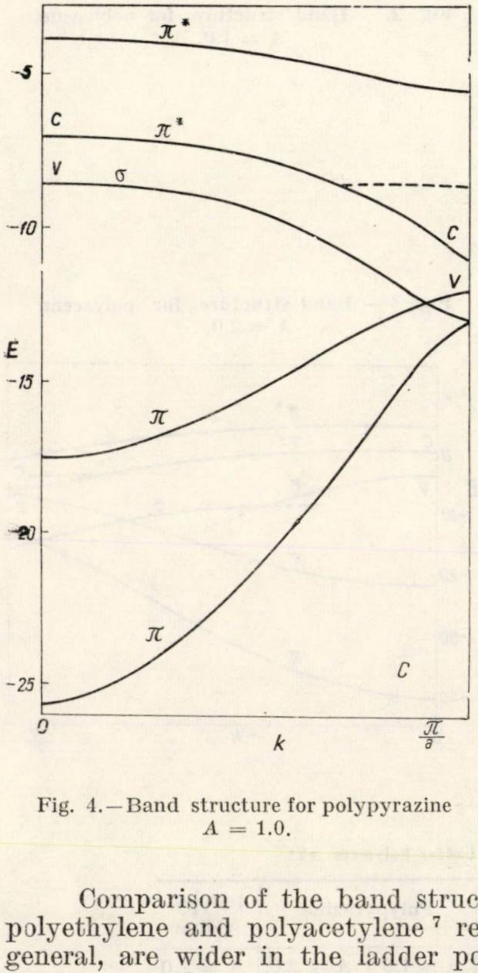

Fig. 4.—Band structure for polypyrazine $A = 1.0$.

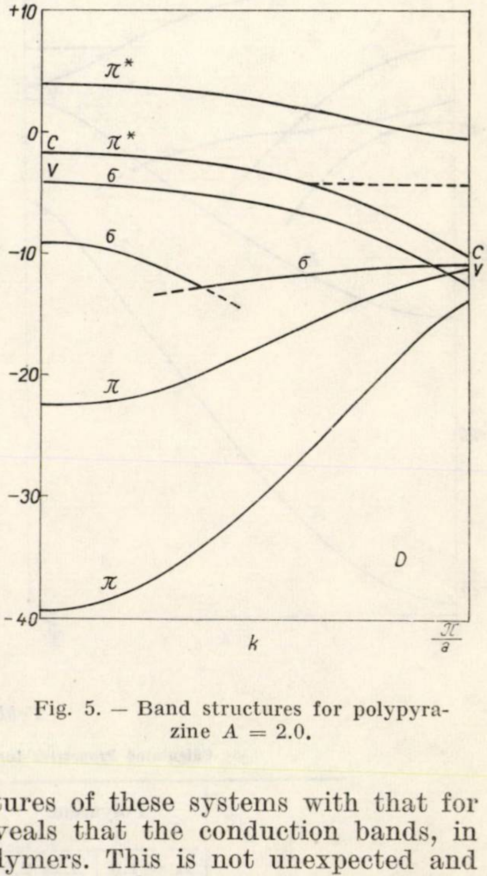

Fig. 5. — Band structures for polypyrazine $A = 2.0$.

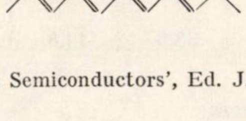
Comparison of the band structures of these systems with that for polyethylene and polyacetylene [7] reveals that the conduction bands, in general, are wider in the ladder polymers. This is not unexpected and stems partly from the fact that the ladder polymer can be regarded as being built from two coupled polyacetylene units, thus



---

[11] J. J. Brophy in 'Organic Semiconductors', Ed. J. J. Brophy and J. Buttrey, Macmillan, New York, 1962, p. 169.

In the polymer studied here, there are essentially no barriers to electron delocalisation in the excited states such as are inherent in molecular crystals such as anthracene. Hence exciton states are essentially buried in the conduction states and the widths of both valence and conduction bands ensure that both the electron and hole pair are fully delocalised. The effective mass of the electrons and holes are those of the free carriers, again on account of the band widths.[12] Hence, both should be efficient carriers. The valence and conduction bands overlap indirectly in each case and the basic conduction properties of the material are expected to be enhanced by this. However, an additional cogent affective factor is the density of states in the region of the direct band gap at $k = \pi/a$ in each case. This will affect the absolute conductance, since at any particular temperature this quantity is governed by the number of electrons

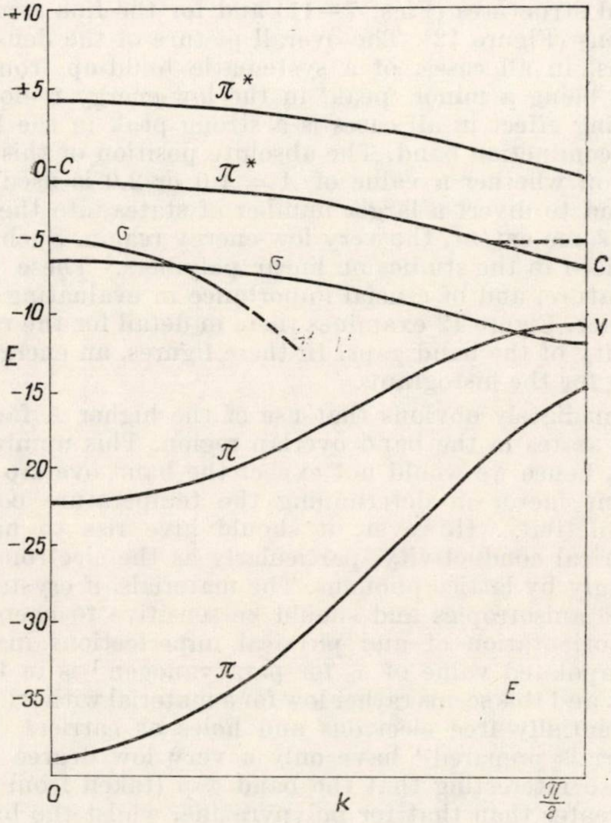


Fig. 6. — Band structure for polypyridine $A = 2.0$.

---

[12] W. Shockley, 'Electrons and Holes in Semiconductors', Van Nostrand, Princeton, N.J., 1950, p. 398.

in the conduction band, which in turn depends critically on the number energetically available in the valence levels. Hence, it is important to consider the *effective band gap*, *i.e.*, the energy gap which is bordered by levels having high densities of states. This leads to an *effective band width* for the π valence band.

The density of states functions are shown histogrammatically for the whole band structures (Figs. 7—11) and for the fine structure in the band gap regions (Figure 12). The overall picture of the density of states (Figs. 7—11) is, in all cases, of a systematic build-up from the lowest energies, there being a minor 'peak' in the low-energy region. However, the most striking effect in all cases is a strong peak in the lower energy regions of the conduction band. The absolute position of this latter sharp peak depends on whether a value of $A = 1.0$ or 2.0 is used. The higher values of A tend to divert a larger number of states into the high-energy region and, to some extent, the very low-energy region. Such effects were previously noticed in the studies on linear polymers.[7] These peaks are an outstanding feature, and of crucial importance in evaluating the physical properties. Hence, Figure 12 examines them in detail for the regions which lie in the vicinity of the band gaps. In these figures, an energy interval of 2eV was taken for the histograms.

It is immediately obvious that use of the higher A factor depletes the number of states in the band overlap region. This number is, in any case, not large, hence we would not expect the band overlap to be a crucially important factor in determining the temperature coefficient for electrical conductivity. However, it should give rise to high absolute values of electrical conductivity, particularly as the electrons will not be scattered strongly by lattice phonons. The materials, if crystalline, should also show large anisotropies and should be sensitive to chemical impurities, and the orientation of and physical imperfections in the crystal. Now, the extrapolated value of σ_0 for paracyanogen [1] is in the region of $10^{-2}\ \Omega^{-1}\ \mathrm{cm}^{-1}$, and this seems rather low for a material with wide electronics bands and essentially free electrons and holes as carriers. This implies that the materials prepared [1] have only a very low degree of polymerisation. It is also interesting that the band gap (taken from Table 2) for polyacene is greater than that for polypyrazine, whilst the band overlaps fall in the reverse order. It we correlate this band overlap with σ_0, the situation is remarkably similar to that found experimentally by Graham and Packham [1] for certain polymers where ΔE shows a good inverse linear correlation with absolute conductance, σ_0. By our calculation this relation does not, however, extend to polypyridine, and Eley [13] has also reported breakdown in this relation.

The temperature coefficient and activation energy for the materials will be determined essentially by the *effective* band gap and, in this context, it is significant from Figure 11 that in no case is there a high density of states lying immediately below the $\pi - \pi^*$ band gap at $k = \pi/a$. Hence, we should expect the effective band gaps for each material to be of the order of 2—4 eV, *i.e.*, somewhat in excess of the measured gaps. The effect-

ive band gap itself may not, however, constitute the thermal excitation energy reported, since (i) by taking the direct $\pi-\pi^*$ band gap we are ignoring the correction which would result from the introduction of configuration interaction in the excited states, (ii) no distinction between excited singlet and triplet states is made in Hückel theory.

Hence, in the next stage of this work we propose to calculate the excited states of some polyacenes, polypyrazines, and the polypyridines in order-firstly, to gauge the effect on the excited states of increasing the number of rings and secondly, to discover what correction to the band gaps the inclusion of electronic interaction brings about.

Revue Roumaine de Chimie, **18**, *6*, 945–952 (1973)

THERMODYNAMIC EXCESS PROPERTIES OF MOLTEN LiCl + KCl, LiCl + RbCl, NaCl + RbCl AND NaCl + CsCl MIXTURES

S. STERNBERG and IUDITA ADORIAN

Polytechnic Institute,
Str. Polizu 1, Bucureşti, Romania

Received December 7, 1972

Partial molar thermodynamic excess functions of the components in molten LiCl+KCl, LiCl+RbCl, NaCl+RbCl and NaCl+CsCl mixtures have been calculated, from cryoscopic and calorimetric data. Equations for thermodynamic activities, excess enthalpies, free enthalpies and entropies of the components in the mixtures mentioned above are established. A statistical interpretation is given to the negative excess entropy of the said mixtures.

Binary mixtures of molten salts that do not yield compounds of definite composition on solidification, have been treated in a first approximation as regular solutions. Their departures from ideality were attributed to the existence of an energy of mixing, the excess entropy has been considered zero.[1]

The appearance of new experimental data that permitted a comparison of the heat of mixing with the free energy of mixing of the same mixture, pointed out the existence of negative excess entropies in a large number of mixtures.[2]

In the present paper partial molar thermodynamic excess functions are calculated for the LiCl+KCl, LiCl+RbCl, NaCl+RbCl, and NaCl+CsCl systems, based on cryoscopic measurements presented in an earlier paper [3] and on calorimetric measurements of Hersh and Kleppa, [4] concerning the same systems.

Thermodynamic activity a_1 of the "solvent" at temperature T has been calculated by the Schroeder-van Laar equation as

$$\ln a_1 = \frac{\Delta H_{T_0}}{R}\left(\frac{1}{T}-\frac{1}{T_0}\right)+\frac{\Delta C_p}{R}\left(\ln\frac{T_0}{T}-\frac{T_0-T}{T}\right) \qquad (1)$$

ΔH_{T_0} is the molar heat of solidification of the pure solvent at its melting point T_0, T the temperature of the first separation of the solvent on cooling the solution, and $C_p = C_p(s) - C_p(l)$ is the difference, regarded as constant, between the molar heat capacities of the solvent in solid and liquid state, respectively.

Partial molar free enthalpies are calculated as

$$\overline{G}_1^E = RT \ln \gamma_1 \tag{2}$$

the subscript 1 being used for the "solvent".

Based on equation (1) and using thermochemical data indicated by Kubaschewski, Evans and Alcock,[5] presented in table 1, we have

Table 1

Thermochemical data

Salt	Temp	ΔH_f kcal/mole	$C_p(s)$ cal/mole deg	$C_p(l)$ cal/mole deg
CsCl	645	4.9 ± 0.1[6]	$0.805 + 17.64 \times 10^{-3} T - 0.89 \times 10^5 T^{-2}$ [6]	$13.86 + 4.2810^{-5} T$[6]
LiCl	610	4.75 ± 0.1[7]	$11 + 3.40 \times 10^{-3} T$[8]	
NaCl	801	6.7 ± 0.1[7]	$10.98 + 3.90 \times 10^{-3} T$[8]	16[8]
RbCl	715	4.4[9]	$11.50 + 2.49 \times 10^{-3} T$[8]	15.3[8]
KCl	772	6.35 ± 0.1[7]	$9.89 + 5.20 \times 10^{-3} T + 0.77 \times 10^5 T^{-2}$ [8]	16[8]

established the following equations for the thermodynamic activities of alkali chlorides:

(ΔC_p of LiCl has been approximated as 1 cal/mole deg)

$$\log a_{\mathrm{LiCl}} = -845.43\ \mathrm{T}^{-1} + 0.5031 \log T - 0.5247 \tag{3}$$

$$\log a_{\mathrm{NaCl}} = -1267.1\ T^{-1} + 0.4182 \log T - 0.0877 \tag{4}$$

$$\log a_{\mathrm{KCl}} = -1249.05\ T^{-1} + 0.3069 \log T + 0.2701 \tag{5}$$

$$\log a_{\mathrm{RbCl}} = -950.1\ T^{-1} + 0.67418 \log T - 1.0573 \tag{6}$$

$$\log a_{\mathrm{CsCl}} = -934.796\ T^{-1} + 0.3421 \log T + 0.00465 \tag{7}$$

The thermodynamic activities of the components in the investigated mixtures, calculated with equations (3) – (7), and the partial molar excess free enthalpies calculated with equation (2) are presented in columns 4 and 5 of tables 2,3,4 and 5.

Kleppa and Hersh [4] have determined the heat of mixing of the systems mentioned above and have given the following equation for the integral heat of mixing

where x is the mole fraction of the MeX component, and the numeric coefficients A, B, C, D and E are given in table 6. Partial molar excess free enthalpies calculated with equation (11) are given in column 5 of tables 2—5.

In the next column of these tables, the partial molar excess entropies are presented as

$$\overline{S}^{E}_{1} = \frac{\overline{H}^{E}_{1} - \overline{G}^{E}_{1}}{T}, \tag{12}$$

where T is the temperature at which the $\overline{G}^{E}_{1}$ free enthalpy is determined. Each of the investigated systems exhibits negative excess entropies. Considering in a first approximation that the molar heat capacities do not change on mixing ($\Delta C_{p_m} = 0$), $\overline{S}^{E}_{\mathrm{Mex}}$ and $\overline{H}^{E}_{\mathrm{Mex}}$ may be considered independent of temperature. Using the values of excess entropies, excess free enthalpies have been recalculated for the temperatures at which the heats of mixing were measured, i.e. 1013°K and 1083°K, respectively. These values calculated as $\overline{G}^E_{1(T_m)} = \overline{G}^E_1 - \overline{S}^E_1 (T_m - T)$ are presented in the last columns of tables 2—5. The partial molar excess free enthalpies are negative, and present departures from the Hildebrand relation for regular solutions: $\overline{G}^E_1 = \beta x_2^2$. The concentration dependence of the $\overline{G}^E_{1(T_m)}$ in the concentration range investigated follows equations of the type

Table 6

Coefficients in equations (11) for partial molar excess enthalpies

CsCl (in NaCl + CsCl)	−2395	8511	−10524

The existence of negative excess entropies can be explained by the existence of a certain degree of order in the mixture, due to a departure from random distribution of the two species of cations in the mixture.[2]

Degree of order σ increases with increases in the energy of mixing. Following a model proposed by Wasastjerna [10] for solid solutions, the degree of order in an equimoleculare solution can be calculated from interaction parameter β by means of relation

---

[10] I. A. Wasastjerna, *Soc. Sci. Fennica. Com. Phys. Math.*, **14**, 3 (1948).

$$\ln \frac{1+\sigma}{1-\sigma} = -\frac{\beta}{2RT} \tag{14}$$

The significance of parameter β is : $\beta = zNw$, where z is the number of next neighbours, N is the Avogadro number and $w = \varepsilon_{1,2} - \frac{1}{2}\varepsilon_1 - \frac{1}{2}\varepsilon_2$ is the change of interaction energy when a mixed ionic group is formed in the mixture. In regular solutions, β is related to the heat of mixing as : $\Delta H_m = \beta\, x_1 x_2$.

For calculating the degree of order in the studied systems, we used values of β calculated in a previous work,[11] based on Lumsden's [12] theory, from the energy of polarization of the anion and the variation of the London forces during mixing. Lumsden's theory accounts well for the behaviour of salt mixtures with a sizeable difference between the cation radii. At the formation of binary molten salt mixtures the vibrational entropy can be considered as constant. The excess entropy that appears is mostly a configurational entropy due to the effect of ordering : $S^E = S^E_{\text{ord}}$.

For the entropy of mixing on solid solutions, Hovi[13] gives the following relation

$$S_m = R\,(x_1 \ln x_1 + x_2 \ln x_2) - R\,(\varkappa \ln \varkappa + \lambda \ln \lambda + \mu \ln \mu + \nu \ln \nu) \tag{15}$$

where $\varkappa$, λ, μ and ν are the probabilities of the formation of a mixed or unmixed ionic triplet, that depend on mole fractions x_1 and x_2 and on the

Table 8

degree of order σ. Equation (15) applied to a binary mixture of molten salts yields the following relation for the excess entropy

$$S^E = 2R\,(x_1 \ln x_1 + x_2 \ln x_2) - R\,(\varkappa \ln \varkappa + \lambda \ln \lambda + \mu \ln \mu + \nu \ln \nu) \quad (16)$$

The values of the degrees of order calculated with equation (13) and the excess entropies of equimolecular mixtures calculated by equation (15) are presented in table 8. In the last column, the experimental values of the integral excess entropies, calculated as: $S^E = x_1\bar{S}_1^E + x_2\bar{S}_2^E$ are presented for equimolecular mixtures. There is a satisfactory agreement between experimental and calculated values.

DIE CHEMISORPTION VON WASSERSTOFF, BENZOL UND CYCLOHEXAN AUF MIT LITHIUM UND TITAN DOTIERTEM ALUMINIUMOXYD. I

ADSORPTIONSISOTHERMEN

I. V. NICOLESCU und AL. FRUMA

Institut für physikalische Chemie
str. Dumbrava Roşie 23, Bukarest, Romania

Eingegangen am 24. November 1972

Es wurde die Chemisorption von Wasserstoff, Benzol und Cyclohexan auf einer Reihe von sechs, mit 0,5 ; 2 und 4 Atom % Li respektiv Ti dotierten Aluminiumoxyde, in einem Gleichgewichtsdruckbereich zwischen 0,5 und 20 Torr, bei der Temperatur von 25 und 250° für den Wasserstoff und 100 und 250° für das Benzol und Cyclohexan untersucht. Die chemisorptive Kapazität der Aluminiumoxyde für den Wasserstoff hängt von der Natur und Konzentration des Dotierstoffs ab, und vermindert sich in folgender Reihenfolge : Aluminiumoxyd dotiert mit 4 ; 2 und 0,5 Atome % Ti, reines Aluminiumoxyd, Aluminiumoxyd dotiert mit 0,5 ; 2 und 4 Atome % Li. Auf Grund der Ergebnisse der Wasserstoffchemisorption, die mit Röntgenstrahl-Beugungsmessungen korreliert wurden, wird je ein Strukturmodell für die mit Lithium und Titan dotierten Aluminiumoxyde vorgeschlagen. Die für das in Oxydform auf der Aluminiumoxydoberfläche befindliche Titan berechnete Oberfläche betrug 1,11 ; 2,94 und 5,4 m^2/g für die Proben mit 0,5 ; 2 bzw. 4 Atom % Ti. Anhand der Darstellung Langmuirs, Temkins und Freundlichs Isothermengleichungen für die Chemisorption des Wasserstoffs, Benzols und Cyclohexans, werden Schlüsse über die Heterogenität der Oberflächen gezogen. Diese Schlüsse sind in Übereinstimmung mit den Röntgenstrahl-Beugungsuntersuchungen.

1. EINLEITUNG

Bei dem Audrücken der Aktivität der Katalysatoren wird nur die Gesamtaktivität der Oberflächen-, Volumen- und Masseneinheit des Katalysators in Betracht genommen. Die Hinweise über die Aktivität der einzelnen Komponente, die von besonderer Wichtigkeit für die Klärung einiger theoretischen Probleme der heterogenen Katalyse und für die praktische Benützung der Katalysatoren sind, kommen sehr selten vor.

Für die Berechnung der spezifischen Aktivität ist es nötig die Gesamtaktivität des Katalysators und seine aktive Oberfläche zu kennen. Bei nicht aufgetragenen Katalysatoren, wie z.B. auf Metalloyxden und Metallpulvern, bei denen die ganze Oberfläche aktiv sein kann, wird diese Oberfläche leicht mit der BET Methode bestimmt. Viel schwieriger ist die

Bestimmung der aktiven Oberfläche bei Katalysatoren mit mehreren Komponenten, bei denen die aktive Oberfläche viel kleiner als die Gesamtoberfläche des Katalysators ist. Wegen der Spezifizität die die Chemisorptionsmethode kennzeichnet, wird die Methode der Gas- und Dampfchemisorption mit Erfolg für die Charakterisierung der aktiven Oberfläche der Katalysatoren, sowohl hinsichtlich der spezifischen Oberfläche und Dispersion als auch der Heterogenität verwendet. [1–3]

Boreskov[4] zeigte schon im Jahre 1952, daß für die Berechnung der spezifischen Oberfläche bei aufgetragenen Platinkatalysatoren, die Bestimmungen sowohl auf dem Katalysator, als auch auf dem Träger nötig sind. In diesem Sinn erschienen nachher zahlreiche Arbeiten [5–8] über die Wasserstoffchemisorption auf Katalysatoren vom Pt/Al_2O_3-Typ, in denen die Gasadsorption separat auf dem Träger und dem Katalysator mit verschiedener Platinkonzentration untersucht wurde. Die Anzahl der Arbeiten über die katalytischen Eigenschaften der Platinkatalysatoren, die auf Grund von mit Fremdionen dotierten Aluminiumoxyde hergestellt wurden ist gering. [9–11] Das Studium der chemisorptiven Eigenschaften dieser Katalysatoren wurde aber gänzlich vernachlässigt, so daß es heutzutage noch keine Arbeit gibt die die Frage inwiefern die Gas- und Dampfchemisorption auf Katalysatoren vom Pt/Al_2O_3-Typ von dem durch Dotierung veränderten Halbleitercharakter des Trägers abhängig ist, beantwortet.

In der vorliegenden Arbeit nahmen wir uns vor, die Ergebnisse der Wasserstoff, Benzol und Cyclohexanchemisorption auf einer Reihe von 6 mit Lithium und Titan dotierten Aluminiumoxyde und auf reinem Aluminiumoxyd das in denselben Bedingungen wie die dotierten Aluminiumoxyde hergestellt wurde, vorzustellen. Diese Aluminiumoxyde benützten wir als Träger für eine Reihe Katalysatoren vom Pt/Al_2O_3-Typ, über deren chemisorptiven und strukturellen Eigenschaften wir später berichten werden.

2. EXPERIMENTELLES

Es wurde eine vorher beschriebene [12] Hochvakuumanlage benützt, mit welcher die Chemisorption des Wasserstoffs, Benzols und Cyclohexans im Druckbereich 0,5 bis 20 Torr bei Temperaturen zwischen 25 und 250° untersucht wurde. Die Druckänderungen im Arbeitsraum wurden mit Hilfe einer Theromröhre und mit einem differenziellem Ölmanometer gemessen.

Es wurden folgende 7 Aluminiumoxydproben benützt: Aluminiumoxyd dotiert mit 0,5; 2 und 4 Atom % Li, Aluminiumoxyd dotiert mit 0,5; 2 und 4 Atom % Ti und eine Etalonprobe mit reinem Aluminiumoxyd. Die Herstellungsweise dieser Aluminiumoxyde wurde vorher berichtet.[13] Die spezifischen Oberflächen wurden auf Grund der Stickstoffadsorption berechnet und betrugen 158, 146, 139, 149, 138 und 124 m^2/g für das Aluminiumoxyd dotiert mit respektiv 0,5; 2; 4 Atom % Li und 0,5; 2 und 4 Atom % Ti, während die spezifische Oberfläche des reinen Aluminiumoxyds 152 m^2/g betrug. Bei den Chemisorptionsmessungen wurden 2 g Proben benützt. Der Wasserstoff wurde durch selektive Absorption und Desorption auf sprödem Palladium[14] gereinigt, während das Benzol und Cyclohexan komerzielle „Merck PA" Ware war, die weiter durch Vakuumverdampfung gereinigt wurde. All diese Reinigungsprozesse wurden in der Anlage, gleich vor den Bestimmungen vorgenommen, so daß die gereinigten Stoffe nicht mehr in Kontakt mit der Atmosphäre zu kommen konnten.

Die während 5 Stunden unter einem Vakuum von 5.10^{-6} Torr bei 500° entgaste Proben, wurden nach der Kühlung den Chemisorptionsbestimmungen bei der vorbestimmten Temperatur und Druck ausgesetzt.

3. ERGEBNISSE UND DISKUSSION

3.1. WASSERSTOFFCHEMISORPTION

Da die Anzahl der experimentellen Ergebnisse die wir uns zu berichten und zu besprechen vornehmen groß ist, beginnen wir mit der Wasserstoffchemisorption auf den Proben mit dotiertem Aluminiumoxyd und reinem Aluminiumoxyd um dann, in den nächsten Abschnitten die Benzol- und Cyclohexanchemisorption zu besprechen.

Die Wasserstoffchemisorption bei der Temperatur von 25° und 250°, in dem Druckbereich 0,5 bis 20 Torr auf 1 g Probe ist in Abb. 1 und respektiv Abb. 2 dargestellt. Aus diesen Abbildungen ergibt sich sofort der große Unterschied zwischen den Wasserstoffchemisorptionsisothermen auf dem mit Titan dotiertem Aluminiumoxyd und dem mit Litium dotiertem oder reinem Aluminiumoxyd. Während die bei Sättigung chemisorbierte Wasserstoffmenge bei 25°, 9,1 μ mol H_2/g auf dem mit 4 Atom % dotiertem Aluminiumoxyd beträgt, ist sie 2,6 μ mol H_2/g auf dem reinen Aluminiumoxyd und nur 1,8 μ mol H_2/g auf dem mit 4 Atom % dotiertem Aluminiumoxyd. Dieser bedeutende Unterschied im chemisorptiven Verhalten der Aluminiumoxyde kann auf keinem Fall den Änderungen der spezifischen Oberflächen nach der Dotierung zugeschrieben werden, da diese Änderungen, wie wir vorher zeigten,[15] nur höchstens 25% betragen. Die große Affinität des Wasserstoffs für die mit Titan dotierten Aluminiumoxyde kann an zwei Ursachen zugeschrieben werden: Änderung der Konzentration und Stärke der aktiven Zentren, oder Übergang von schwachen, der physikalischen Adsorption eigenen Bindungen, zu stärkeren Chemisorptionsbindungen, die zu einem hohen Bedeckungsgrad führen.

Für die erste dieser Möglichkeiten spricht die beobachtete fast geradlinige Änderung der Sättigungsadsorption mit der Titankonzentration.

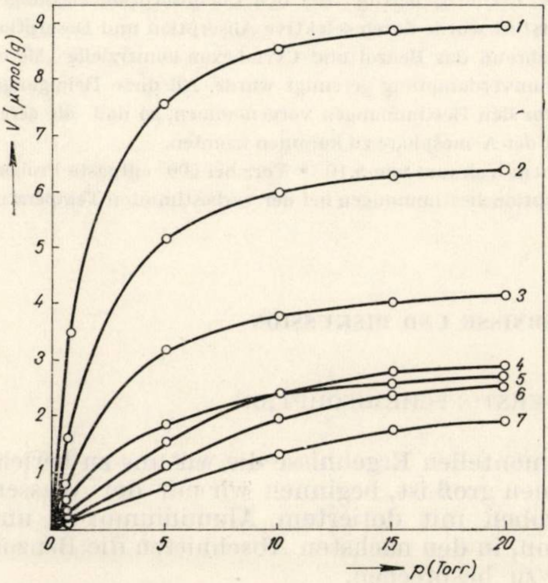

Abb. 1. — Isothermen der Wasserstoffchemisorption bei 25° auf folgenden dotierten Aluminiumoxyden:

4 Atom % Ti (*1*); 2 Atom % Ti (*2*); 0,5 Atom % Ti (*3*); 0,5 Atom % Li (*4*); reines Aluminiumoxyd (*5*); 2 Atom % Li (*6*) und 4 Atom % Li (*7*).

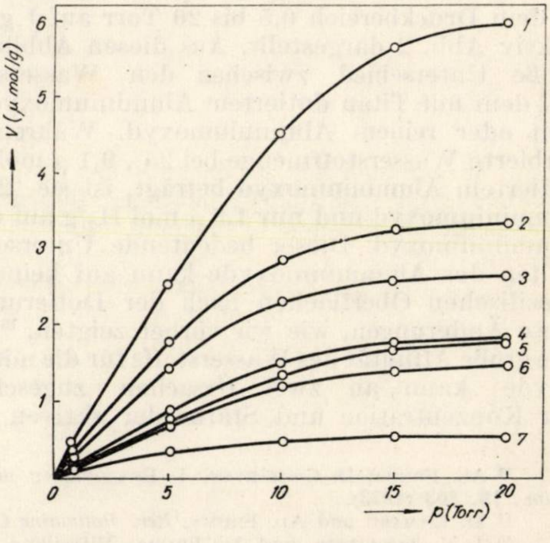

Abb. 2. — Isothermen der Wasserstoffchemisorption bei 250° auf folgenden dotierten Aluminiumoxyden:

4 Atom % Ti (*1*); 2 Atom % Ti (*2*); 0,5 Atom % Ti (*3*); reines Aluminiumoxyd (*4*); 0,5 Atom % Li (*5*); 2 Atom % Li (*6*) und 4 Atom % Li (*7*).

Dieses weist daraufhin, daß sich die Adsorptionszentren mit großer Affinität für Wasserstoff allmählich mit der Titanmenge im Aluminiumoxyd bilden. Da die Wasserstoffchemisorption auf diesen Aluminiumoxyden eine Oberflächenerscheinung ist, ergibt sich die Schlußfolgerung, daß sich das Titan größtenteils auf die Oberfläche lagert und demnach nicht in die Aluminiumoxydmasse eindringt. Zum gleichen Schluß kamen wir auch infolge der Besprechung der Röntgenstrahlen-Diffraktogramme, die wir für diese Proben ausführten [13]. Es ist ersichtlich, daß in den Beugungsspektren nur das Bild des Al_2O_3 vorkommt, das weite Höchstwerte aufweist. Diese Tatsache und die Bemerkung, daß sich die interplanären Abstände des mit Titan dotierten Aluminiumoxyds gegenüber dem reinen Aluminiumoxyd nur betrefflich der Spaltung des Höhepunkts bei 1,99 Å änderten,[16] führten zur Schlußfolgerung, daß sich das Titanoxyd fein dispergiert auf der Oberfläche der Al_2O_3 Partikeln befindet. In dieser Weise stimmen die Ergebnisse der Chemisorption mit den durch Röntgenstrahlenbeugung erhaltenen Strukturbetrachtungen.

Die zweite Möglichkeit und zwar die Änderung infolge der Dotierung der Bindungsweise zwischen der adsorbierten Phase und dem Aluminiumoxyd, kann die beobachteten Unterschiede nicht erklären, da es gut bekannt ist, [17–19] daß die Temperatur von 25° die geeigneteste Temperatur für die Wasserstoffchemisorptionsmessungen ist. Bei dieser Temperatur ist bei der Sättigung eine Höchstbedeckung der Oberfläche mit einer chemisorbierten Wasserstoffschicht gesichert, was sich auch aus der Form der Isothermen, die schon bei Drücken unter 20 Torr einem Gleichwert streben, ergibt.

Unsere Schlüsse bezüglich der Struktur der mit Titan dotierten Aluminiumoxyde müssen sich in den Gleichungen der Adsorptionsisothermen die den Heterogenitätszustand der Oberfläche angeben unvermittelt widerspiegeln. In Abb. 3–5 stellen wir die experimentellen Ergebnisse in Koordinaten entsprechend der Langmuir-, Temkin- und Freundlich--Adsorptionsisothermengleichung dar. Langmuirs Gleichung, die eine homogene Oberfläche voraussetzt, ist von keinem System bestätigt. Temkins Gleichung, die einer „gleichmäßig nichthomogener" Oberfläche, wie sie Roghinski [20] nennt, entspricht, wird durch die Wasserstoffchemisorption auf das reine Aluminiumoxyd, auf allen mit Lithium dotierten Aluminiumoxyden und auf das mit 0,5 Atom % Ti dotiertem Aluminiumoxyd bestätigt, während Freundlichs Gleichung, die der Chemisorption auf einer sehr heterogenen Oberfläche entspricht, von der Wasserstoffchemisorption auf mit Titan dotierten Aluminiumoxyde bestätigt wird. Das Auftragen des Titans auf der Oberfläche der Aluminiumoxydpartikeln ist die Ursache der besonderen Heterogenität dieses Aluminiumoxydtyps. Infolge einer größeren Anzahl von Titanatomen ist die chemisorptive

4 Atom % Li (*1*) ; 0,5 Atom % Li (*2*) ; reines Aluminiumoxyd (*3*) ; 0,5 Atom % Ti (*4*) und 4 Atom % Ti (*5*).

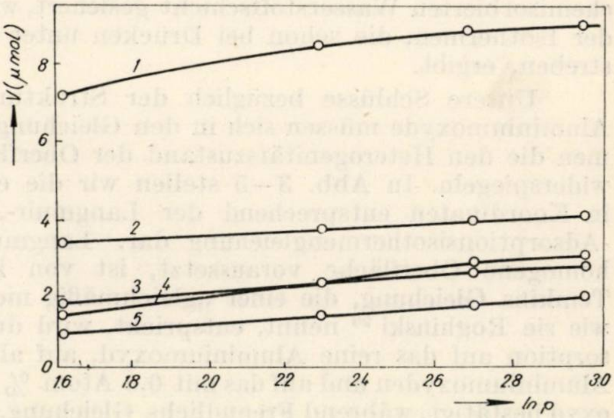

Abb. 4. — Darstellung der Temkin Isothermgleichung für die Wasserstoffchemisorption bei 25° auf folgenden dotierten Aluminiumoxyden :

4 Atom % Ti (*1*) ; 0,5 Atom % Ti (*2*) ; reines Aluminiumoxyd (*3*) ; 0,5 Atom % Li (*4*) und 4 Atom % Li (*5*).

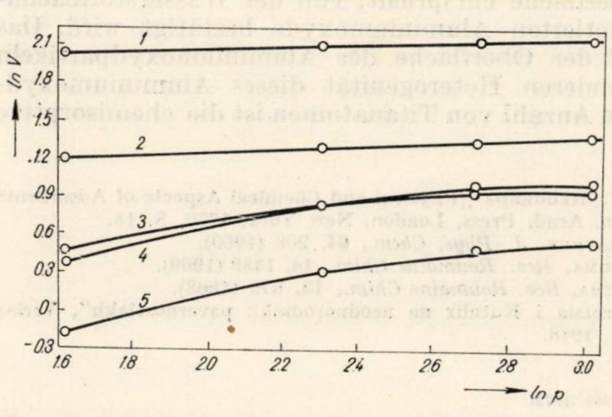

Abb. 5. — Darstellung der Freundlich Isothermgleichung für die Wasserstoffchemisorption bei 25° auf folgenden dotierten Aluminiumoxyden :

4 Atom % Ti (*1*) ; 0,5 Atom % Ti(*2*) ; reines Aluminiumoxyd (*3*) ; 0,5 Atom % Li (*4*) und 4 Atom % Li (*5*).

Kapazität der dotierten Aluminiumoxyde entsprechend größer, aber der Mechanismus der gegenseitigen Wirkung bleibt unverändert.

Gegenüber dem Wasserstoff weisen die mit Lithium dotierten Aluminumioxyde ein gänzlich verschiedenes Verhalten als die titandotierten Aluminiumoxyde auf, und zwar mit dem Ansteigen der Lithiumkonzentration in den Proben, fällt die chemisorptive Kapazität. Bei der Temperatur von 25° sind die Unterschiede zwischen den Sättigungschemisorptionen der mit 0,5 ; 2 und 4 Atom % Li dotierten Aluminiumoxyde und dem reinen Aluminiumoxyd gering und übertreffen nur wenig die Genauigkeit der experimentellen Methode. Auch bei dieser Temperatur bemerkt man eine Verminderung der Adsorption in der Reihenfolge : 0,5 ; 2 und 4 Atom % Li. Bei höherer Temperatur bleibt die Reihenfolge unverändert und die Chemisorption ist im ganzen Druckbereich geringer als die auf dem reinen Aluminiumoxyd. Dieses Verhalten der lithiumdotierten Aluminiumoxyde, wie auch die Tatsache, daß sich Temkin's Gleichung, die einer „gleichmäßig nichthomogener" Oberfläche entspricht, bewährt, weist daraufhin, daß das Lithium im Gitter des Aluminiumoxyds eindringt und ein bei der Wasserstoffchemisorption nicht aktives Aluminat bildet, dessen Konzentration im Aluminiumoxyd mit der Dotierungsmasse wächst.

Für die Prüfung dieser Voraussetzung führten wir auch die Röntgenstrahlendiffraktogramme der mit Lithium dotierten Aluminiumoxyde aus. Zum Unterschied zu den mit Titan dotiertem Aluminiumoxyd, weist das mit Litium dotierte Aluminiumoxyd im Diffraktionsspektrum die charakteristischen Linien des Litiumaluminats $LiAl_5O_8$ Form I und II auf. Zu diesem Schluß gelangten wir durch das Vergleichen der Beugungshöchstwerte bei 2,809 Å, 1,40 und 1,96—1,99 Å.[13] Es ist ersichtlich, daß der für die Form I und II spezifische Höhepunkt bei 2,809 Å schmal ist und mit der Vergrößerung der Lithiumkonzentration zunimmt. Die flache Form des Höhepunkts bei 2,30 Å und 1,40 Å deutet auf eine größere Gitterordnung in den betreffenden Kristallebenen, wo ein größerer Beitrag der Aluminium und Sauerstoffatomen als der Lithiumatomen vorhanden ist. Wir zeigten, [13] daß die Änderung der Intensitäten der Linie bei 2,809 Å mit der Konzentration der Li^+ Ionen daraufhin deutet, daß das Lithiumaluminat freie oktaedrische Plätze besitzt, die durch Dotierung allmählich mit den Li^+ Ionen von $Al\,[Li\square_{0,5-x}\,Al_{1,5}]\,O_4$ bis $Al\,[Li_{0,5}\,Al_{1,5}]\,O_4$, wo $0 < x < 0,5$, besetzt werden.

Da wir bewiesen, [13] daß in unseren Herstellungsbedingungen das Titan nicht im Aluminiumoxydgitter eindringt, sondern sich in Form von dispergiertem Oxyd auf der Oberfläche befindet, versuchten wir auf Grund unserer Wasserstoffchemisorption Ergebnisse, eine Dispersionsberechnung für diese Proben vorzunehmen. Wir unternahmen darum einige Wasserstoffchemisorptionmessungen auf einer TiO_2 Etalonprobe, die aus $Ti(NO_3)_4$ in denselben Bedingungen wie das mit Titan dotierte Aluminiumoxyd hergestellt wurde. Das Titanoxyd kommt in Rutilform (tetragonal, a=4,59 Å, c=2,95 Å) vor. Bei 25° betrug seine Sättigungschemisorption 6,8 μ mol H_2/g für eine spezifische Oberfläche von 5,4 m^2/g. Da es experimentell unmöglich ist einige Daten zu ermitteln, wie z.B. die Oberflächendichte des Titanoxyds aus unseren Proben, das Verhältnis, aus der Gesamtmenge, das sich auf der Aluminiumoxydoberfläche befindet und die Anzahl der chemisorbierten Wasserstoffatome die einem Oberflächengebilde TiO_2 entspricht, könnten wir eine vollständige Berechnung der Dispersion, wie sie gewöhnlich bei der Bestimmung der Partikelgröße bei aufgetragenen Metallkatalysatoren ausgeführt wird, nicht vollbringen. Auf Grund der Daten die wir besitzen ist es möglich Wellers [21] Berechnungsmethode anzuwenden. Diese Methode gestattet das gegenseitige Vergleichen der Dispersion des TiO_2 aus den entsprechenden Proben und führt zur Ermittelung der Oberfläche die dem TiO_2 aus der Gesamtoberfläche der Probe ankommt, ohne aber als Endresultat eine Partikelgröße anzugeben. Im Folgenden werden wir diese Berechnung unternehmen.

Aus den in Abb. 1 dargestellten Chemisorptionisthermen wird durch Subtraktion die chemisorbierte Wasserstoffmenge des auf der Oberfläche befindlichen Titanoxyds ermittelt. Bei den Proben mit 4;2 und 0,5 Atom % Ti beträgt diese Menge respektiv 6,4; 3,7 und 1,4 μ mol H_2/g Probe. Auf einem Gramm TiO_2 bezogen ist die chemisorbierte Wasserstoffmenge respektiv 102, 118 und 178μ mol $H_2/g\ TiO_2$. Angenommen, daß sowohl auf dem dotierten Aluminiumoxyd als auch auf die Etalonprobe der Mechanismus derselbe ist, wird 1 g TiO_2 aus den dotierten Aluminiumoxyden um 102/6,8 = 15, 0; 118/6,8 = 17,35 und 178/6,8 = 26,2 mehr Wasserstoff als 1 g TiO_2 aus der Etalonprobe adsorbieren. Es ergibt sich dadurch, daß das auf der Oberfläche des Aluminiumoxyds befindliche TiO_2 im Vergleich zu der Etalonprobe 15,0; 17,35 und 26,2 mal dispergierter, bei den mit 4; 2 und 0,5 Atom % Ti dotierten Proben, vorkommt. Mit der Zunahme der Konzentration des Dotierstoffs, wird die Dispersion vermindert. Diese Erscheinung war zu erwarten, da größere Oberflächenkonzentrationen das Wachstum im Volumen der Oberflächenkristalliten fördert.

Die Berechnung der Oberfläche die dem TiO_2 aus dem dotierten Aluminiumoxyd ankommt kann nur in der Annahme, daß sich die Gesamtmenge des TiO_2 auf der Oberfläche befindet, ausgeführt werden. Diese Annahme kann nicht geprüft werden, aber für sie plädieren die Chemisorptionsmessungen und Röntgenstrahlenbestimmungen die wir mehr oben besprachen. Wenn 6,8 μ mol H_2 auf 5,4 m^2 der Etalonprobe chemisorbiert werden, dann werden sich 6,4; 3,7 und 1,4 μ mol H_2 auf 5,10; 2,94 und 1,11 m^2 auf den mit respektiv 4; 2 und 0,5 Atom % Ti dotierten Aluminiumoxyde chemisorbieren. Im Vergleich zu der über 100 m^2 großen Gesamtoberfläche der dotierten Aluminiumoxyde, ist die Oberfläche die dem Titan ankommt klein. Dieses könnte eine Ursache für das Fehlen der charakteristischen Linien des Rutils im Diffraktionspektrum der mit Titan dotierten Aluminiumoxyde sein.

3.2. BENZOLADSORPTION

Wir untersuchten die Adsorption der Benzoldämpfe bei der Temperatur von 100° in dem Druckbereich 0,5 bis 20 Torr. In Abb. 6 und

---

[21] S. Weller und S. E. Voltz, *J. Amer. Chem. Soc.*, **75**, 5227 (1953).

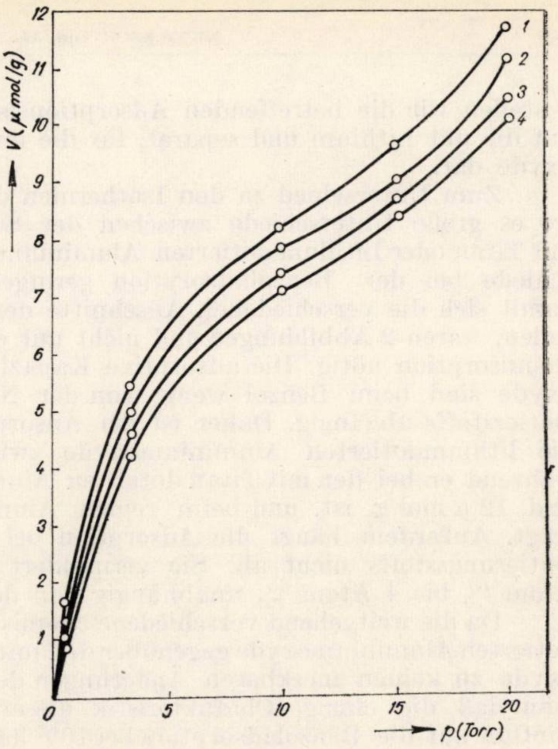

Abb. 6. — Isothermen der Benzoladsorption bei 100° auf folgenden dotierten Aluminiumoxyden :

0,5 Atom% Li (*1*) ; reines Aluminiumoxyd (*2*) ; 2 Atom% Li (*3*) und 4 Atom % Li (*4*)

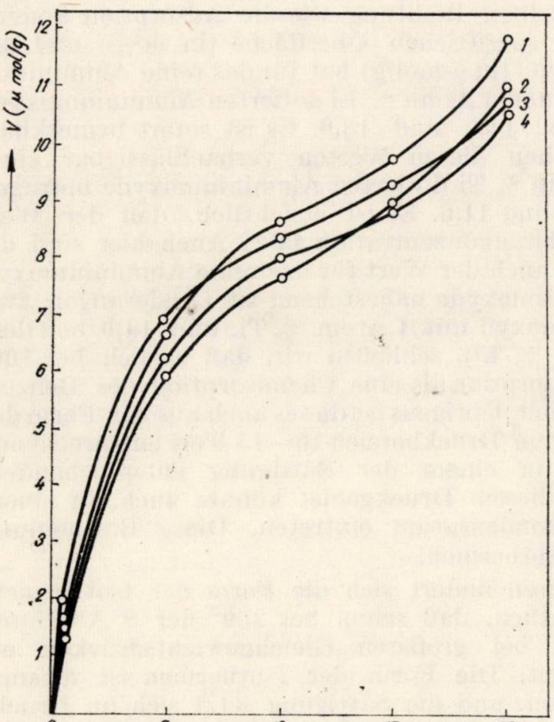

Abb. 7. — Isothermen der Benzoladsorption bei 100° auf folgenden dotierten Aluminiumoxyden :

0,5 Atom% Ti (*1*) ; reines Aluminiumoxyd (*2*) ; 2 Atom % Ti (*3*) 4 Atom % Ti (*4*).

7 stellen wir die betreffenden Adsorptionsisothermen für die Adsorption auf die mit Lithium und separat, für die mit Titan dotierten Aluminiumoxyde dar.

Zum Unterschied zu den Isothermen der Wasserstoffchemisorption, wo es große Unterschiede zwischen der Sättigungsadsorption auf den mit Titan oder Lithium dotierten Aluminiumoxyde gab, sind diese Unterschiede bei der Benzoladsorption geringer. Aus diesem Grund und damit sich die verschiedenen Abschnitte der Isothermen nicht schneiden sollen, waren 2 Abbildungen und nicht nur eine, wie bei der Wasserstoffchemisorption nötig. Die adsorptive Kapazität der dotierten Aluminiumoxyde sind beim Benzol wenig von der Natur und Konzentration des Dotierstoffs abhängig. Daher ist der Adsorptionsbereich bei 20 Torr für die lithiumdotierten Aluminiumoxyde zwischen 10 und 11,7 μ mol/g, während er bei den mit Titan dotierten Aluminiumoxyden zwischen 10,7 und 12 μ mol/g ist, und beim reinen Aluminiumoxyd 11,2 μ mol/g beträgt. Außerdem hängt die Adsorption bei 20 Torr von der Natur des Dotierungsstoffs nicht ab. Sie vermindert sich bei Dotierung von 0,5 Atom % bis 4 Atom %, unabhängig von der Natur des Dotierungsions.

Da die weitgehend verschiedene chemische Struktur der mit Lithium dotierten Aluminiumoxyde gegenüber den mit Titan dotierten Aluminiumoxyde zu keinen merkbaren Änderungen der Adsorption führt, schließt man, daß die einzige Charakteristik dieser Aluminiumoxyde die einen Einfluß auf die Benzoladsorption bei 100° hat, die spezifische Oberfläche ist, die sich genau in der selben Richtung wie die Adsorption ändert. Das Verhältnis zwischen der spezifischen Oberfläche (in m^2/g) und der Adsorption bei 20 Torr und 100° (in μ mol/g) hat für das reine Aluminiumoxyd und für die mit 0,5 ; 2 und 4 Atom % Li dotierten Aluminiumoxyde folgende Werte : 13,7 ; 13,5 ; 14,0 und 13,9. Es ist sofort bemerkbar, daß die Unterschiede zwischen diesen Werten vernachlässigbar sind. Für die mit 0,5 ; 2 und 4 Atom % Ti dotierten Aluminiumoxyde betrugen diese Verhältnisse 12,5 ; 12,5 und 11,6. Es ist ersichtlich, daß der Wert dieser Verhältnisse mit der Titankonzentration fällt. Auch hier sind die Unterschiede sehr gering. Da auch der Wert für das reine Aluminiumoxyd und für die dotierten Aluminiumoxyde nahestehend ist (Änderungen zwischen 11,6 bei dem Aluminiumoxyd mit 4 Atom % Ti, und 14,0 bei dem Aluminiumoxyd mit 2 Atom % Li), schließen wir, daß es sich bei 100° eher um eine physikalische Adsorption als eine Chemisorption des Benzols auf dem Aluminiumoxyd handelt. Übrigens ist dieses auch aus der Form der Isothermen ersichtlich. Der dem Druckbereich 10—15 Torr entsprechende Isothermenteil steigt, statt in einem der Sättigung entsprechendem Gleichwert überzugehen. In diesem Druckgebiet könnte auch, in einem gewissen Maß die Kapillarkondensation eintreten. Diese Erscheinung verursacht meistens S-Typ Isothermen.

Bei höheren Temperaturen ändert sich die Form der Isothermen. Aus Abb. 8 und 9 ist ersichtlich, daß schon bei 250° der S Abschnitt der Isothermen, der bei 100° bei größeren Gleichgewichtsdrücken erscheint, nicht mehr vorkommt. Die Form der Isothermen ist diesmal klassisch für die Chemisorption, und die Sättigung setzt sich im Druckbereich 15—20 Torr für alle Proben ein. Die Reihenfolge der Sättigungsadsorptionen ist der bei 20 Torr und 100° verschieden. Zum Unterschied zu der Adsorption bei 100°, wo die Sättigungswerte nur von der spezifischen Oberfläche abhängen, was die physikalische Adsorption bei dieser Temperatur charakterisierte, ist die Benzolchemisorption bei 250° sowohl von der spezifischen Oberfläche, als auch von der Natur des Dotierstoffs

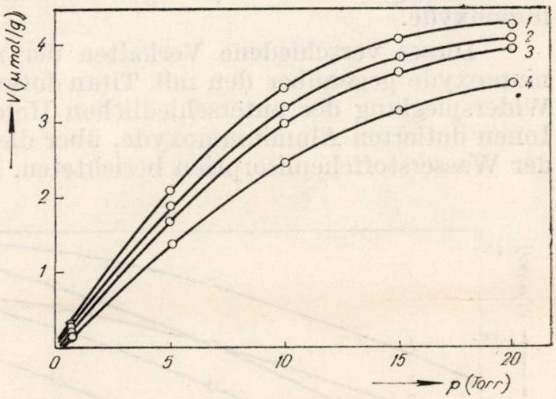

Abb. 8. – Isothermen der Benzoladsorption bei 250° auf folgenden dotierten Aluminuimoxyden :

0,5 Atom % Li (*1*) ; 2 Atom % Li (*2*) ; reines Aluminiumoxyd (*3*) und 4 Atom % Li (*4*).

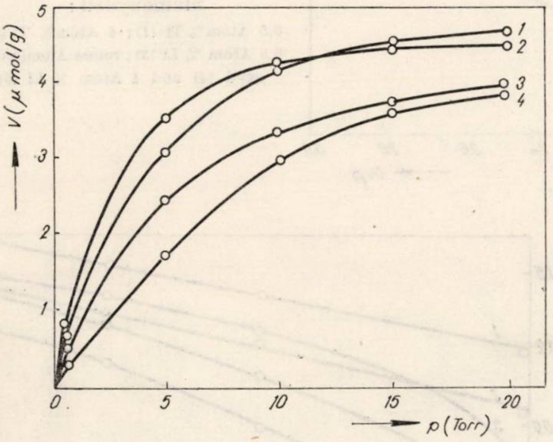

Abb. 9. – Isothermen der Benzoladsorption bei 250° auf folgenden dotierten Aluminiumoxyden :

0,5 Atom % Ti (*1*) ; 2 Atom % Ti (*2*) ; 4 Atom % Ti (*3*) und reines Aluminiumoxyd (*4*).

abhängig. Für die mit Titan dotierten Aluminiumoxyde ist die Sättigungsadsorption immer größer als die des reinen Aluminiumoxyds. Die Tatsache, daß die Sättigungschemisorption bei dem 0,5 Atom % Ti dotiertem Aluminiumoxyd größer ist als die bei dem 4 Atom % Ti dotiertem Aluminiumoxyd kann sowohl mit der größeren spezifischen Oberfläche, als auch mit der höheren Dispersion bei der Probe mit 0,5 Atom % Ti in Verbindung gesetzt werden.

Die größten Unterschiede zwischen der auf dem reinen Aluminiumoxyd entsprechenden Isotherme und die Chemisorptionisothermen auf den dotierten Aluminiumoxyde kommen bei Gleichgewichtsdrücken zwischen 0,5 und 5 Torr vor, demnach im Gebiet der geringen Bedeckungsgraden. Dieses weist auf die Tendenz der mit Titan dotierten

Aluminiumoxyde sich schneller als das reine Aluminiumoxyd zu sättigen, was durch den ersten stark steigenden Abschnitt der Isothermen zum Vorschein kommt. Dadurch wird auch die Schneidung der Isothermen der mit 0,5 und 2 Atom % Ti dotierten Aluminiumoxyde bedingt. All diese Erscheinungen sind viel geringer bei den mit Lithium dotierten Aluminiumoxyde.

Dieses verschiedene Verhalten der mit Lithium dotierten Aluminiumoxyde gegenüber den mit Titan dotierten Aluminiumoxyden ist eine Widerspieglung der unterschiedlichen Heterogenität der mit verschiedenen Ionen dotierten Aluminiumoxyde, über die wir mehr bei der Besprechung der Wasserstoffchemisorption berichteten. In Abb. 10 und 11 bringen wir die Adsorptionsisothermen des Benzols bei 250° auf den dotierten Aluminiumoxyden und dem reinen Aluminiumoxyd in Koordinaten entsprechend Temkins und Freundlichs Isothermengleichung dar. Wie erwartet, sind die Ergebnisse der Benzoladsorption in guter Übereinstimmung mit denen die wir über die Heterogenität der Oberfläche bei der Wasserstoffchemisorption besprochen haben. Aus Abb. 10 ist ersichtlich, daß sich Temkins Adsorptionsisotherm, die eine gleichmäßig nichthomogene Oberfläche

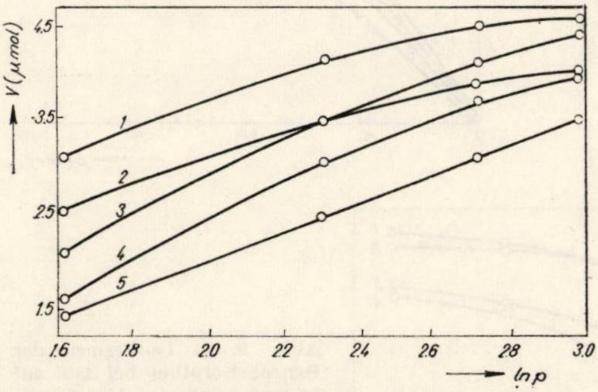

Abb. 10. — Darstellung der Temkin Isothermgleichung für die Benzoladsorption bei 250° auf folgenden dotierten Aluminiumoxyden:

0,5 Atom% Ti (*1*); 4 Atom% Ti (*2*); 0,5 Atom % Li (*3*); reines Aluminiumoxyd (*4*) und 4 Atom % Li (*5*).

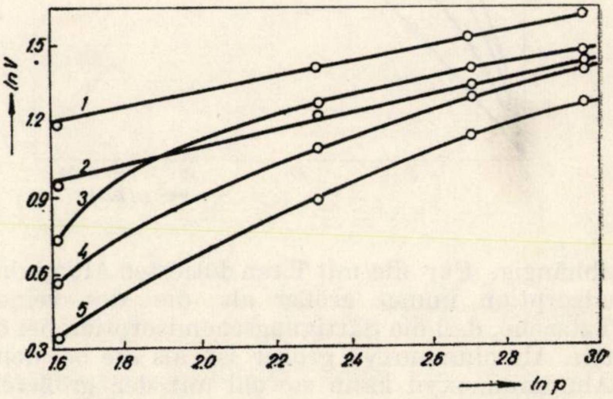

Abb. 11. — Darstellung der Freundlich Isothermgleichung für die Benzoladsorption bei 250° auf folgenden dotierten Aluminiumoxyden:

0,5 Atom% Ti (*1*); 4 Atom % Ti (*2*); 0,5 Atom % Li (*3*); reines Aluminiumoxyd (*4*) und 4 Atom % Li (*5*).

voraussetzt, dem mit 4 Atom % Li dotiertem Aluminiumoxyd vortrefflich, und dem mit 0,5 Atom % Li dotiertem Aluminiumoxyd ziemlich gut anpaßt. Die anderen Aluminiumoxyde, die eine weitgehende Heterogenität besitzen, bestätigen nicht Temkins Gleichung, sondern Freundlichs Gleichung, wie aus Abb. 11 ersichtlich ist. All diese Ergebnisse sind in guter Übereinstimmung mit den Strukturbetrachtungen die wir auf Grund der Besprechung der Röntgenstrahlen Diffraktogramme, wie wir auch bei der Wasserstoffchemisorption zeigten, vorführten.

Da die adsorptiven Eigenschaften der dotierten Aluminiumoxyde für das Benzol nur wenig von der chemischen Natur dieser Aluminiumoxyde abhängig sind, und demnach nicht spezifisch sind, ist eine Dispersionsbestimmung oder die Schätzung der Oberfläche eines Komponents, ähnlich wie bei der Wasserstoffchemisorption, nicht möglich.

3.3. CYCLOHEXANADSORPTION

Die Adsorption des Cyclohexans wurde im Temperaturbereich 100—250° bei Gleichgewichtsdrücken zwischen 0,5 und 20 Torr untersucht. Da bei 100° die Adsorptionsisothermen ähnlich denen des Benzols sind, stellten wir nur die Isothermen des Cyclohexans bei 250° dar, wo das Verhalten des Cyclohexans ganz verschieden wie das des Benzols ist. Auch bei 100° kommen aber einige Unterschiede gegenüber den Benzoladsorptionsisothermen vor, und zwar defindet sich die bei 20 Torr adsorbierte Menge zwischen 6 und 8μ mol Cyclohexan/g, d.h. weniger als beim Benzol, und der S Abschnitt der Isothermen, der die physikalische Adsorption und die kapillare Kondensation charakterisierte, erscheint beim Cyclohexan, wahrscheinlich wegen der größeren Volatilität, nicht mehr. Bei der Cyclohexanadsorption bei 100° sind die Unterschiede zwischen dem adsorptiven Verhalten den mit Lithium dotierten, gegenüber den mit Titan dotierten Aluminiumoxyde.gering. Dieses weist daraufhin, daß bei dieser Temperatur der Effekt der spezifischen Oberfläche und nicht die chemische Natur maßgebend ist. Es ist demnach ein Gebiet der physikalischen Adsorption das für besondere Auslegungen nicht geeignet ist.

In Abb. 12 stellten wir die Isothermen der Cyclohexanchemisorption auf den dotierten Aluminiumoxyden und auf dem reinen Aluminiumoxyd vor. Von Anfang an bemerkt man einen deutlichen Unterschied gegenüber den Isothermen des Benzols auf diesen Aluminiumoxyden, bei derselben Temperatur. Die dem reinen Aluminiumoxyd entsprechende Isotherme hat eine mittlere Lage zwischen den Isothermen die dem mit Lithium und Titan dotierten Aluminiumoxyd entsprechen. Dieses ist dem Verhalten bei der Wasserstoffchemisorption sehr ähnlich und dem bei der Benzolchemisorption beobachteten Verhalten entgegengesetzt. Der Effekt der spezifischen Oberfläche ist vernachlässigbar, da die Sättigungsadsorptionen nur von der chemischen Natur der Aluminiumoxyde und von der Konzentration des Dotierstoffs abhängen. Die Werte der Sättigungsadsorptionen ändern sich in der Reihenfolge: Aluminiumoxyd dotiert mit 4 Atom % Ti — 2 Atom % Ti — 0,5 Atom % Ti — reines

Aluminiumoxyd — Aluminiumoxyd dotiert mit 0,5 Atom % Li — 2 Atom % Li — 4 Atom % Li, von 5 bis 2,5 μ mol/g. In Vergleich zu der Wasserstoffchemisorption bleibt bei dieser Temperatur die Reihenfolge unverändert, aber der Wertebereich ist viel geringer.

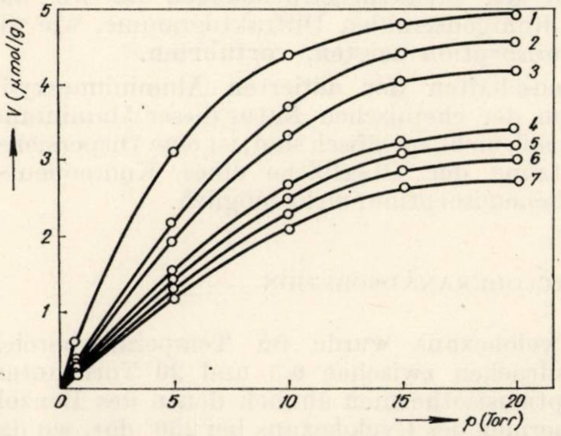

Abb. 12. — Isothermen der Cyclohexanadsorption bei 250° auf folgenden dotierten Aluminiumoxyden :

4 Atom % Ti (*1*) ; 2 Atom % Ti (*2*) ; 0.5 Atom % Ti (*3*) ; reines Aluminiumoxyd (*4*) ; 0.5 Atom % Li (*5*) 2 Atom % Li (*6*) und 4 Atom % Li (*7*).

Auf Grund der Isothermgleichung der Cyclohexanadsorption werden wir einige Schlüsse über die Heterogenität des dotierten und reinen Aluminiumoxyds ziehen. Unsere Aufgabe ist festzustellen in welchem Maße die Chemisorption des Cyclohexans die Ergebnisse der Wasserstoff- und Benzolchemisorption bezüglich der Prüfung der Temkin und Freundlich Gleichung bestätigt.

In Abb. 13 und 14 stellten wir die Resultate der Cyclohexanchemisorption bei 250° in Koordinaten entsprechend Temkins und Freundlichs Isothermengleichung dar. Es ist ersichtlich, daß die Schlüsse die wir bei der Wasserstoff und Benzolchemisorption über die fortgeschrittene Heterogenität der titandotierten Aluminiumoxyde feststellten, auch von diesen experimentellen Ergebnissen bestätigt werden. Man bemerkt bei den beiden Darstellungen, daß sich die Punkte die dem Druck von 20 Torr entsprechen, nicht auf den Geraden befinden, sondern gegen geringere Werte der Adsorption verschoben sind. Diese Tatsache ist der Sättigung der Oberfläche bei Drücken unter 20 Torr zu verdanken, wie aus Abb. 12 ersichtlich ist. Da bei den anderen Gleichgewichtsdrücken die experimentellen Punkte auf den Geraden gut angepaßt sind, und zwar für die Chemisorption des Cyclohexans auf mit Titan dotiertem Aluminiumoxyd die Freundlich Gleichung, während für das mit Lithium dotierte Aluminiumoxyd die Temkin Gleichung bestätigt wird, bleiben unsere Schlüsse gültig.

Auf Grund der Struktur der mit Titan dotierten Aluminiumoxyde die wir vorher besprachen, wir auch wegen den Unterschieden zwischen der Chemisorption auf die Titan dotierten gegenüber den Lithium dotierten Aluminiumoxyde, versuchten wir die Oberfläche die dem Cyclohexan bei 250° auf das Titanoxyd, das sich auf der Aluminiumoxydoberfläche befindet, ankommt zu ermitteln. Zum Unterschied zu der Berechnung die

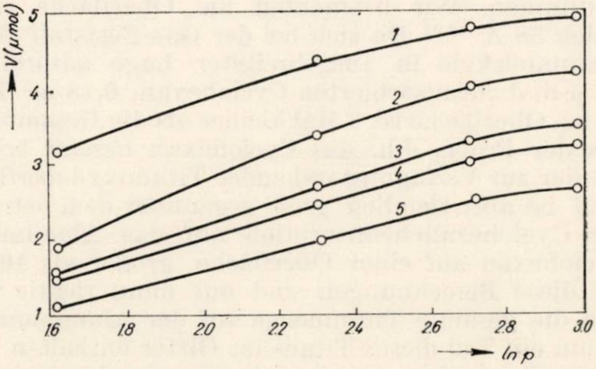

Abb. 13. – Darstellung der Temkin Isothermgleichung für die Cyclohexanadsorption bei 250° auf folgenden dotierten Aluminiumoxyden : 4 Atom % Ti (*1*) ; 0,5 Atom% Ti (*2*) ; reines Aluminiumoxyd (*3*) ; 0,5 Atom% Li (*4*) und 4 Atom % Li (*5*).

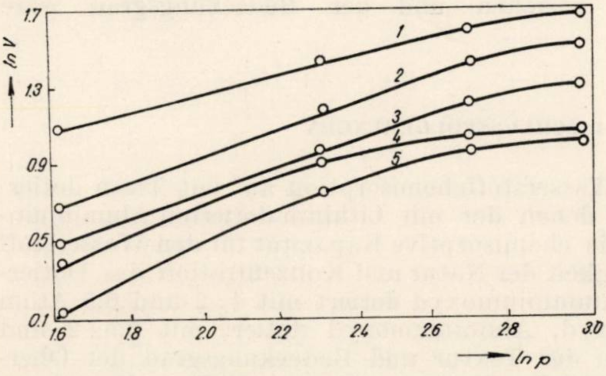

Abb. 14. – Darstellung der Freundlich Isothermgleichung für die Cyclohexanadsorption bei 250° auf folgenden dotierten Aluminiumoxyden : 4 Atom % Ti (*1*) ; 0,5 Atom % Ti (*2*): reines Aluminiumoxyd (*3*) ;0,5 Atom%. Li (*4*) und 4 Atom % Li (*5*).

wir bei der Wasserstoffchemisorption ausführten erscheinen bei der Cyclohexanchemisorption einige Schwierigkeiten die mit dem Gleichgewicht Gas-Feststoff verbunden sind. Die Temperatur von 250°, für die wir die Berechnung ausführen, ist hoch genug damit neben der eigentlichen Adsorption auch in einem gewissen Maße die Desorption einwirkt· Dieses kommt durch die ständige Verminderung der Sättigungsadsorption mit der Temperatur zum Vorschein. Die Adsorption bei der von uns gewählten Temperatur ist dadurch nur ein mittlerer Wert zwischen der großen, bei tieferer Temperatur, physikalisch und chemisch adsorbierten Menge, und der geringen chemisorbierten Menge bei höherer Temperatur wo die Desorption maßgebend sein kann und der Bedeckungsgrad klein ist. Da wir nur die gesamtadsorbierte Dampfmenge bestimmen, d.h. die Summe der Adsorptionen auf dem Titanoxyd und dem Aluminiumoxyd, können wir nicht deuten in welchem Maße die Desorption, die bei 250° erscheint den Bedeckungsgrad des Titanoxyds gegenüber dem Aluminiumoxyd beeinflußt. Durch das Abziehen der Cyclohexanmenge das auf dem Aluminiumoxyd chemisorbiert wurde aus der Gesamtmenge des auf der Probe, z.B. mit 0,5 Atom % Ti, chemisorbierten Cyclohexans, kann man die Cyclohexanmenge die auf dem Titanoxyd bei 250° chemisorbiert wurde berechnen, ohne aber behaupten zu können, daß die Gesamtoberfläche des Titanoxyds bedeckt wurde. Da wir aber anhand der Wasserstoffchemisorption berechneten, daß diese Oberfläche 111 m^2/g für das mit 0,5 Atom % Ti dotierte Aluminiumoxyd beträgt, können wir den Teil aus dieser Oberfläche der bei 250° mit Cyclohexan bedeckt ist bestimmen. Wir betrachten die Oberfläche eines Cyclohexanmoleküls gleich 38 $\mathring{A}^2$[22,23] Da sich bei der Gas-Feststoff Wechselwirkung die Cyclohexanmoleküle in ausgebreiteter Lage adsorbieren,[24] entsprechen dem 0,8 μ mol chemisorbierten Cyclohexan, 0,18 m^2 Titanoxyd aus der Probe. Diese Oberfläche ist 6 Mal kleiner als die Gesamtoberfläche des Titanoxyds aus der Probe, d.h. das Cyclohexan besetzt bei Sättigung bei 250° nur 1/6 der zur Verfügung stehender Titanoxydoberfläche. Dieser Bedeckungsgrad ist aber ziemlich groß gegenüber dem betreffenden Bedeckungsgrad der Cyclohexanchemisorption auf das Aluminiumoxyd, wobei 3,4 μ mol Cyclohexan auf einer Oberfläche größer als 100 m^2 adsorbiert werden. All diese Berechnungen sind nur dann richtig wenn man annimmt, daß sich die gesamte Titanmenge auf der Aluminiumoxydoberfläche befindet. Wenn ein Teil dieses Titans im Gitter enthalten und der Adsorption nicht zugänglich wäre, würde sich die adsorbierte Cyclohexanmenge auf eine geringere Titanoberfläche beziehen und der Bedeckungsgrad wäre größer als 1/6.

4. SCHLUSSFOLGERUNGEN

Die Isothermen der Wasserstoffchemisorption auf mit Titan dotierten Aluminiumoxyde sind denen der mit Lithium dotierten Aluminiumoxyde sehr verschieden. Die chemisorptive Kapazität für den Wasserstoff vermindert sich in Abhängigkeit der Natur und Konzentration des Dotierstoffs in der Reihenfolge : Aluminiumoxyd dotiert mit 4 ; 2 und 0,5 Atom % Ti, reines Aluminiumoxyd, Aluminiumoxyd dotiert mit 0,5 ; 2 und 4 Atom % Li. Sie ist von der Textur und Bedeckungsgrad der Oberfläche unabhängig. Auf Grund der Bestätigung Freundlichs Adsorptionsisothermgleichung von den mit Titan dotierten Aluminiumoxyde wurden Schlüsse über die Heterogenität der Oberfläche dieser Aluminiumoxyde gezogen. Diese Schlüsse, zusammen mit den röntgenographischen diffraktometrischen Untersuchungen, gestatteten die Ausführung eines Strukturmodells für die mit Titan dotierten Aluminiumoxyde, gemäß dem sich der größte Teil der durch Dotierung eingeführten Titanionen, in Form von TiO_2 auf der Aluminiumoxydoberfläche wiederfinden. Durch den Vergleich der Ergebnisse der Wasserstoffchemisorption auf den dotierten Aluminiumoxyde gegenüber einer TiO_2 Etalonprobe, berechneten wir, daß in den 0,5 ; 2 und 4 Atom % Ti dotierten Aluminiumoxyde, das TiO_2 respektiv 1,11 ; 2,94 und 5,4 m^2/g beträgt. Für die mit Lithium dotierten Aluminiumoxyde sind wir der Ansicht, daß die Oberflächen gleichmäßig nichthomogen sind, und daß die Homogenität mit dem Lithium-

gehalt wächst. Das Lithium dringt im Aluminiumoxydgitter ein und bildet folgendes Aluminat $Al\,[Li_x\square_{0,5-x}Al_{1,5}]O_4$.

Aus den Isothermen der Benzoladsorption auf den dotierten Aluminiumoxyden ergab sich die Unabhängigkeit der Sättigungsadsorption von der Natur des Dotierstoffs und die maßgebende Rolle der spezifischen Oberfläche. Wegen der Nichtspezifizität der Benzoladsorption konnte eine Dispersionsberechnung nicht unternommen werden. Die Schlüsse der Röntgenstrahlen Diffraktogramme und Wasserstoffchemisorption über die Heterogenität der Oberflächen werden auf Grund der Darstellung der experimentellen Ergebnisse in Koordinaten entsprechend Temkins und Freundlichs Adsorptionsisothermen bestätigt.

Die Chemisorption des Cyclohexans auf den dotierten Aluminiumoxyde weist eine ähnliche Spezifizität wie bei der Wasserstoffchemisorption beobachtete auf. Die Reihenfolge der Verminderung der chemisorptiven Kapazität ist von den titandotierten zu den lithiumdotierten Aluminiumoxyde dieselbe wie bei der Wasserstoffchemisorption. Man schätzte, daß bei 250° der Bedeckungsgrad mit Cyclohexan des Titanoxyds auf der Oberfläche des mit 0,5 Atom % Ti dotierten Aluminiumoxyds, etwa 16,2 % beträgt. Die vorherigen Schlüsse über die Heterogenität der Oberfläche werden auch von der Chemisorption des Cyclohexans bestätigt.

Wir sind der Ansicht, daß die Entwicklung dieser Forschung zu einer besseren Kenntnis der Beziehungen zwischen der Oberflächenchemie, des Gas-Feststoff Gleichgewichts und Heterogenität, im Verhältnis zu der Struktur der Moleküle die adsorbiert werden und zu den Herstellungsbedingungen der dotierten Aluminiumoxyde führen kann.

SPECTRAL STUDY OF SOME MIXED LIGAND COMPOUNDS OF LANTHANIDES

P. SPACU and SILVIA PLOŞTINARU

Institute of Physical Chemistry, Dumbrava Roşie, 23, Bucharest, Romania

Received December 15, 1972

A series of ternary compounds with a general formula LnL_2X_3 (where Ln=La, Ce, Pr, Nd, Sm, Eu, Tb, Dy, Er; X=bromomandelic and chlorosalicylic acid and L=-*o*-phenanthroline and 5,6-dimethylphenantroline) were synthetized and studied. The type of coordination of the ligands was established by the study of their IR spectra. The electronic visible spectra inform us on the hypersensitivity and allow us to calculate the nephelauxetic ratio and the covalency degree of the Pr(III) and Nd(III) compounds.

Carrying further our studies[1] on new compounds of lanthanide carboxylates with nitrogen donor atom organic bases, we have obtained and studied a new series of coordination compounds of lanthanide bromomandelates and chlorosalicylates with *o*-phenanthroline and 5,6-dimethylphenanthroline.

The new compounds obtained have the general formula:

LnL_2X_3 where: Ln = La, Ce, Pr, Nd, Sm, Eu, Tb, Dy, Er.
X = bromomandelic acid (BrMand)
$Br-C_6H_4-CHOH-COOH$
5–chlorosalicylic acid (ClSal)
$HO-C_6H_3-Cl-COOH$
L = *o*-phenanthroline (phen)
5,6-dimethylphenanthroline (DMPh)

RESULTS AND DISCUSSIONS

A spectral study was carried out on the new synthetized compounds in order to establish the character of the chemical bonding and ability of "f" orbitals to participate to the chemical bond formation. To this purpose we have therefore studied the UV and visible electronic spectra as well as the IR spectra.

---

[1] P. Spacu and S. Ploştinaru, *Rev. Roumaine Chim.*, **17**, 697 (1972).

The UV spectra recorded in ethanol and methanol solutions ($C = 10^{-5}M$) are practically identical to the spectra of the free ligands. The characteristic maxima of phenanthroline and 5,6-dimethylphenanthroline appear in all the complexes. The high values of the extinction molar coefficients of the compounds (table 1) are in good agreement with the fact that two basic molecules enter into the composition of the complexes. The absorption bands of the chlorosalicylic acid at 233 and 314 nm are covered by the more intense bands of the *o*-phenanthroline and, respectively, 5,6-dimethylphenanthroline.

Table 1

Absorption maxima in UV for free ligand and its lanthanide compounds

λ nm	$\varepsilon \times 10^{-4}$	Ln (phen)$_2$(BrMand)$_3$			Ln(phen)$_2$(ClSal)$_3$	
		$\varepsilon \times 10^{-4}$			$\varepsilon \times 10^{-4}$	
	phen	Ce	Eu	Nd	Nd	Eu
230	3.48	8.28	8.68	8.63	9.41	9.35
264	3.28	4.36	4.56	4.48	6.03	5.80

The electronic spectra in the visible range recorded on the solid state as well as on DMF and benzene solutions are practically identical. This shows that in the solution too there prevail the same species as in the solid state. The specific bands of the central metal ion which appear, are due to the transition of the electrons from the ground level to the "J" excited levels. The visible spectra of these complexes give us informations on two important factors: the hypersensitivity and nephelauxetic ratio. These factors are determined by the changes due to the coordination which are taking place in the absorption spectrum of the free ion. These changes were experimentally observed by comparing the absorption spectrum of the aquo-ion to the absorption spectrum of the respective complex (figure 1).

No significant changes are generally observed in the intensity or frequency of the absorption bands of the complexes compared to the aqua-ion, which shows a weak participation of the 4*f* orbitals to the formation of the chemical bonds. We may nevertheless mention some *f*—*f* transitions which seem to be intensified by coordination (table 2).

The table 2 shows an increase in the intensity of the absorption bands of the complexes compared to the aquo-ion; there also appears an increase of these band intensities for the complexes with a substituted ligand compared to those with an unsubstituted ligand. This latter is due to the increase of the electronic density around the nitrogen atoms, brought about by the electro-donor influence of the methyl groups, leading to the strengthening of the chemical nitrogen-metal bonds.

Table 2
Hypersensitive transitions

Ln^{3+}	Transition	$\tilde{\nu}$ (10^{-3}) cm^{-1}	ε_1	ε_2	ε_3	ε_4
Nd^{3+}	$^4I_{9/2} \rightarrow {}^4G_{5/2}$	17.3	7.08	15.92	16.62	18.29
	$\rightarrow {}^4G_{7/2}$	19.2	3.58	5.68	6.77	8.36
Pr^{3+}	$^3H_4 \rightarrow {}^3P_2$	22.5	9.04	10.60	11.34	13.02

ε_1 = molar extinction coefficients for aquo ion.
ε_2 = molar extinction coefficients for $Ln(phen)_2\ (ClSal)_3$.
ε_3 = molar extinction coefficients for $Ln(phen)_2\ (BrMand)_3$.
ε_4 = molar extinction coefficients for $Ln(DMPh)_2\ (BrMand)_3$.

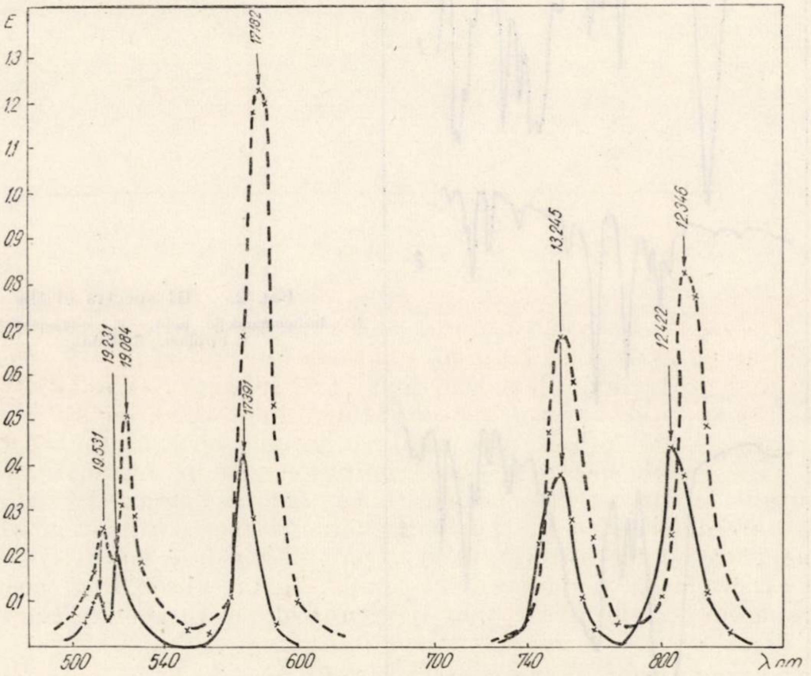

Fig. 1. – The visible absorption spectra of the ——— aquo ion ; – – – $Nd(phen)_2\ (BrMand)_3$.

The shifts taking place in the position of the absorption bands, though small, have nevertheless permitted us to calculate the parameter β (the nephelauxetic ratio)[2] and the covalency degree δ.[3] These were calculated for Pr(III) and Nd(III) complexes and are of the same order of magnitude as in the case of complexes with chloromandelic acid.[1] In the case of erbium there appear no shifts of the absorption bands, but only their intensification.

IR SPECTRA

We have examined the IR spectra of the studied ternary complexes to determine the way in which the anions and the bases coordinate with the central metal ion. These spectra are rather complicated, and their interpretation is somewhat difficult due to the overlapping of the frequencies of the coordinate *o*-phenanthrolines on those of the coordinate oxyacids. To study them, we have recorded the IR spectra of the respective oxyacids, of the free bases and of the ternary complexes (figure 2, table 3). For a better comparison, in some cases, we have also determined the spectrum of the corresponding simple salt. By analysing these spectra we have observed a series of changes in the spectrum of the complexes *vs.* the spectrum of the free ligands, changes appearing owing to the coordina-

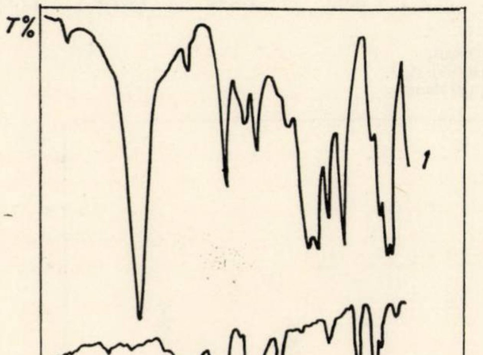

Fig. 2. — IR spectra of the *1*, bromomandelic acid. *2*, *o*-phenanthroline. *3*, $Pr(phen)_2(BrMand)_3$.

tion. Strong bands were identified in the 700–1750 cm^{-1} range, but most important to watch are the bands in the 1350–1750 cm^{-1} range, where the C = N, C = C vibrations of the *o*-phenanthroline ring appear, as well as the OCO vibration frequencies of the respective acids.

The monobasic aliphatic acids show a strong absorption of the carbonyl group between 1705–1720 cm^{-1}.[4] The substitution by a halogen or CN^- group, results in the shift of the absorption range of the carbonyl group towards higher frequencies[5]; thus for bromomandelic acid, the frequency of the carbonyl group appear at 1735 cm^{-1}. This frequency is moved by coordination and appears in the complexes under the form of two bands corresponding to the asymmetric vibration OCO ($\nu_{as} \approx 1610$ cm^{-1}) and the symmetric vibration OCO ($\nu_s \approx 1400$ cm^{-1}). The strong band at 1600–1610 cm^{-1} appears to be very broad owing to the overlapping with the triplet of the coordinate phenanthroline (1600 cm^{-1}). Also the bands of the free phenanthroline spectrum at 1425 and 1500 cm^{-1} appear to be moved towards higher frequencies as a consequence of the coordination.

In the case of 5-chlorosalicylic acid, which can form intermolecular hydrogen bonds stabilized through a chelatic conjugation, the frequency of the carbonyl group decreases, appearing at 1670 cm^{-1}. As for compounds with bromomandelic acid we find intense bands in two frequency ranges :

[4] J. FLETT, *J. Chem. Soc.*, **1951**, 962.

[5] L. J. BELLAMY, "The Infra-red Spectra of Complex Molecules", Methuen, London, 1962.

1. — 1600 — 1500 cm^{-1} where the C=C,C=N frequencies of phenanthroline appear (1620 cm^{-1} şi 1525 cm^{-1}) as well as the asymmetric OCO stretching vibration of the chlorosalicylic acid (1580 cm^{-1}). In the Nd(III) chlorsalicylate ν_{as} appears at a lower value (1550 cm^{-1}) as in the case of ternary complexes. The higher value of the ν_{as} frequency in this case may be interpreted as showing a higher covalency degree as for the simple neodimium salt.

2. — 1450 — 1360 cm^{-1}, bands of the coordinate *o*-phenanthroline (1435 cm^{-1}) as well as the band corresponding to the OCO symmetric vibration frequency (1370 cm^{-1}) of the chlorosalicylic acid.

The same changes also appear in the complexes with 5,6-dimethylphenanthroline, which show the fact that the ligands do participate in the coordination with the central metal ion.

EXPERIMENTAL

The ternary complexes were obtained from an aqueous solution by the same methods as in the former paper.[1]

The analytical data and the chemical formulas of the new compounds obtained are systematized on table 4.

The compounds thus obtained are solid anhydrous substances and very stable in time. They are difficult to solve in most of the usual organic solvents, but easy enough to solve in dimethylformamide and dimethylsulphoxide, and the compounds with chlorosalicylic acid

are soluble in benzene and chloroform. A qualitative study of the solubility of these compounds in different solvents show that it changes according to the oxycarboxylic acid in the molecule, in the following order :

Chlorosalicylic > *Chloromandelic* > *Bromomandelic*

Also, as the radius of the lanthanide ion decreases, the solubility decreases too, so that the Dy(III) and Er(III) complexes with bromomandelic acid are very hard to solve even in DMF.

Measurements of molar conductivity in anhydrous methanol and DMF give values within $8-11\ \Omega^{-1}\ cm^2 mol^{-1}$ in the case of methanol solutions and between $18-20\ \Omega^{-1}\ cm^2\ mol^{-1}$ in the DMF solution. The values for the obtained molar conductivity show, according to the data from literature,[6] that in these solvents none of the compounds undergoes practically any noticeable dissociation, behaving as non-electrolytes.

Reagents. The following reagents were used : oxides (Ln_2O_3) of spectral purity (Matthey and Johnson) ; $Ce(NO_3)_3$ (E. Merck-puriss) ; *o*-phenanthroline E. Merck p.a.) ; 5,6-dimethylphenanthroline (Fluka AG-Switzerland) ; bromo-mandelic acid (Fluka AG-Switzerland) ; Chlorsalicylic acid (BDH).

Apparatus. IR spectra of the free ligands and its metal complexes were recorded on a UR-10 spectrophotometer in the $4000-700\ cm^{-1}$ range. UV and visible spectra in DMF and benzene solutions were recorded using an VSU$-$2 spectrophotometer. Concentration of the solutions were $\approx 10^{-5}$ M in the case of UV and $\approx 10^{-2}$ M in the case of visible spectra. The reflectance spectra at room temperature were recorded on a spectrophotometer VSU$-$1 using MgO as a standard. Electric conductivity of the complexes was determined with OK$-$102/1 conductometer on solutions of absolute methanol and DMF.

Acknowledgement. We express our thanks to Mrs. M. Popa for the carbon, hydrogen and nitrogen microanalyses.

SUR LA CHLORATION ET L'OXYCHLORATION SPÉCIFIQUES DES CYCLOHEPTÈNE ET CYCLOPENTÈNE

FRANÇOIS GAYMARD, ROGER GUEDJ et ANDRÉ VERMEGLIO

Laboratoire de Chimie Structurale Organique — Université de Nice —
U.E.R.M.S.T. — Campus Valrose — 06 Nice 02

Reçu le 25 novembre 1972

La chloration et l'oxychloration ménagées du cyclopentène et du cycloheptène sont étudiées en système dynamique en phase gazeuse, avec recyclage des produits transformés. L'obtention en quantité prépondérante de dérivés *trans*-Dichlorés 1,2 (plus de 90 % pour les deux cycloalcènes) est remarquable dans la réaction de chloration. L'oxychloration est caractérisée par la faible réactivité et même la non-réactivité de l'oxygène vis-à-vis de ces deux alcènes. La comparaison des résultats de l'oxydation, de la chloration et de l'oxychloration des cyclopentène, cycloheptène et cyclohexène montre le comportement différent du chlore et de l'oxygène, et permet de préciser les mécanismes proposés dans le cas de ce dernier hydrocarbure. Plus particulièrement, la stéréochimie permet de comprendre la différence de réactivité du chlore et de l'oxygène vis-à-vis de chaque alcène.

L'oxydation, notamment par l'oxygène moléculaire, des matières organiques constitue une importante technique industrielle de synthèse.

On peut cependant noter, à travers les résultats bibliographiques fort nombreux, que l'oxydation en phase gazeuse d'hydrocarbures aliphatiques, cycliques ou alicycliques, est caractérisée par le manque de sélectivité.

A titre d'exemple, signalons que Fisch et Brown[1] dans l'oxydation du méthyl-2 hexadécane à 300° décomptent près de 160 produits ! !

Cette absence de sélectivité justifie les interprétations très divergentes constatées dans la littérature. On peut néanmoins dégager quatre axes qui correspondent aux analyses les plus vraisemblables des mécanismes d'oxydation : l'isomérisation de Semenov,[2] l'isomérisation de Shtern,[3] la théorie d'Yenikolopyan,[4] la théorie oléfinique de Knox.[5]

[5] M. A. Knox, *Chem. Comm.*, **1965**, 108.

En réalisant la chloration et l'oxychloration des cyclopentène, cyclohexène[6] et cycloheptène, nous pensions apporter une contribution à l'étude des mécanismes attachés à ces processus radicalaires. Cette « série » s'adaptait, semble-t-il, parfaitement aux problèmes posés dans la mesure où les différences de structures pouvaient rendre compte de la compétition entre le chlore et l'oxygène vis-à-vis de ces alcènes.

La variation de paramètre tels que la température du réacteur et le rapport O_2/Cl_2 nous semblait être un moyen d'atteindre d'une part cet objectif et d'autre part de rendre dans une certaine mesure les réactions plus sélectives.

PARTIE EXPÉRIMENTALE

Le choix des conditions expérimentales a été dicté essentiellement par une double exigence : Nécessité d'obtenir de forts rendements et de fortes concentrations en produits transformés : Nécessité de diminuer la possibilité de participation à un deuxième étage de réaction des produits initialement transformés.

Le dispositif déjà décrit [7,8] permet l'oxydation ou la chloration ménagée en système dynamique avec extraction en continue des « produits lourds » ; il est donc assez bien adapté à cette double exigence.

Les conditions expérimentales correspondent à celles du mémoire précédent.[6]

ANALYSE. La quasi-totalité des produits de réaction a été identifiée selon les techniques usuelles : distillation du mélange brut de réaction — chromatographie des fractions ainsi obtenues — récupération en C.P.P.V. — vérification de leur pureté sur une colonne analytique apolaire et sur une colonne analytique polaire — identification par spectrométrie de Masse, I.R., R.M.N. — enfin, synthèse des différents isomères dans les cas douteux où les méthodes physiques ne sont pas suffisantes.

Les divers résultats analytiques et quantitatifs (les pourcentages pondéraux ont été corrigés après étalonnage par C.P.V.) sont indiqués dans les tableaux 1 (chloration) et 2 (oxychloration).

DISCUSSION

MÉCANISMES DE LA CHLORATION

Dans une précédente publication,[6] nous avions discuté en particulier les mécanismes de dichloration et proposé la première partie du schéma 1 pour expliquer la stéréosélectivité de la réaction (obtention de 85% de *trans*-Dichloro-1,2 cyclohexane).

En ce qui concerne la chloration du cyclopentène et du cycloheptène, la stéréospécificité est encore plus caractéristique. Dans les deux cas, les pourcentages de produits dichlorés sont supérieurs à 90%. Les *trans*-

[8] R. GUEDJ, Thèse, Orsay, 1966.

Dichloro-1,2 cyclopentane et *trans*-Dichloro-1,2 cycloheptane peuvent être justifiés par une attaque en deux étapes par le chlore, mécanisme analogue à celui proposé dans le cas du cyclohexène (schéma 1).

	trans-Dichloro-1,2 cycloheptane	90 %
	cis-Dichloro-1,2 cycloheptane	1 %

* Entre 250 et 450°, la répartition des produits de chloration pour ces différents alcènes est sensiblement la même : les seules différences concernent des produits tels que le naphtalène, l'indène... qui dérivent d'une pyrolyse amorcée par les atomes de chlore et qui se trouvent de ce fait en moins grandes quantités aux températures plus basses.

Les produits secondaires — dans la chloration du cyclopentène — le monochlorocyclopentane d'une part, l'indène et le naphtalène d'autre part proviennent respectivement de l'addition de gaz chlorhydrique sur la double liaison (monochlorocyclopentane) et d'une isomérisation thermique probable (indène et naphtalène).

La comparaison des résultats obtenus dans la série C_5H_8, C_6H_{10}, C_7H_{12} permet d'apprécier l'influence de la structure sur le mécanisme de chloration :

En effet, les résultats expérimentaux laissent apparaître deux faits importants :

— primo, sélectivité de la réaction qui se traduit par l'apparition prépondérante de *trans*-Dichloro-1,2 cycloalcanes,

Tableau 2

— secundo, présence, certes faible, de *cis*-Dichloro-1,2 cyclohexane et de *cis*-Dichloro-1,2 cycloheptane comparée à l'absence totale de *cis*-Dichloro-1,2 cyclopentane.*

Les pourcentages de *trans*-Dichloro-1,2 cycloalcanes dans les trois cas suggèrent une réactivité très prononcée de la double liaison, liée à l'accès facile de cette dernière par le chlore radicalaire.

En effet, dans les cas des cyclopentène, cyclohexène et cycloheptène, la géométrie de ces molécules montre clairement qu'il n'y a aucun empêchement stérique à l'approche de la double liaison par le chlore radicalaire.

L'absence de *cis*-Dichloro-1,2 cyclopentane comparée à la présence des homologues supérieurs présente sur la plan théorique un intérêt non négligeable, bien que ces composés soient très peu abondants dans nos mélanges réactionnels (1,5 % et 1 %).

Ces différences peuvent justifier les mécanismes avancés pour expliquer la formation des *trans* dichloro-cycloalcanes. Le schéma 1 montre clairement que les radicaux chloro-2 cyclohexyle et chloro-2 cycloheptyle, formés dans une première étape, sont susceptibles de changer de conformation ; une nouvelle attaque du chlore peut alors conduire aux composés *trans* et aux composés *cis* (voie II *b* et II *c*). Par contre, il n'est pas possible, compte tenu de la rigidité du cycle en C_5, d'envisager une inversion de conformation pour le radical chloro-2 cyclopentyle. La nouvelle attaque du chlore, qui se fait sur la face la plus accessible, conduira seulement au *trans*-Dichloro-1,2 cyclopentane.

On peut dégager un deuxième aspect théorique important lié à l'absence de *cis*-Dichloro-1,2 cyclopentane. En effet, il n'était pas déraisonnable de penser que l'attaque de la double liaison puisse se faire par le chlore moléculaire suivant un mécanisme concerté (schéma 2).

---

* L'absence de *cis*-Dichloro-1,2 cyclopentane a pu être vérifiée par comparaison des temps de rétention d'un échantillon authentique et de ceux des produits de la fraction brute.

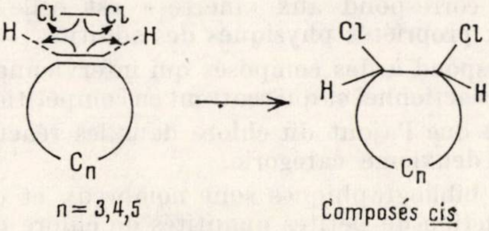

Schéma 2.
Attaque de la double liaison par le chlore moléculaire selon un mécanisme concerté.

Cette hypothèse pouvait à la rigueur être retenue dans le cas du cycloheptène et du cyclohexène, avec, somme toute, une contribution très faible pour expliquer les dérivés dichlorés *cis* 1,2 du cycloheptane et du cyclohexane. Du fait de l'absence de *cis*-Dichloro-1,2 cyclopentane on ne peut en tout état de cause, l'avancer pour justifier l'obtention de ces produits : l'approche de la double liaison par le chlore pouvant se faire dans les trois cas de façon identique.

Remarquons que Ashton et Tedder dans deux récentes publications,[9,10] en étudiant la chloration en phase gazeuse des chlorocyclohexane et chlorocyclopentane, envisagent les mêmes intermédiaires que nous-mêmes (les radicaux chloro-2 cycloalykles) et expliquent le grand rapport *trans/cis* des produits dichlorés (12/1 dans le cas du C_6 et 16/1 dans le cas du C_5) par une interaction entre l'orbitale π à moitié remplie des radicaux chloro-2 cycloalkyles et l'orbitale atomique 3 p_z du chlore. Cette théorie n'est pas du tout contradictoire avec les voies IIb et IIc de notre schéma 1.

MÉCANISMES DE L'OXYCHLORATION

A – POSITION DU PROBLÈME :

De nombreux auteurs [11 à 19] ont étudié l'influence d'additifs dans les réactions d'oxydation. A quelles fins ? Probablement pour initier et pour orienter dans une certaine mesure les réactions d'oxydations caractérisées par leur manque de sélectivité.

[19] P. Goldfinger, G. Huybrechts, G. Martens, L. Meyers et J. Olbreghts, *Trans. Faraday Soc.*, **61**, 1933 (1965).

Les additifs sont en première approximation classées selon leur nature en deux catégories :

— la première qui correspond aux «inertes» est celle qui est associée essentiellement aux propriétés physiques des additifs,

— la seconde correspond à des composés qui interviennent véritablement dans le processus réactionnel et qui rentrent en compétition avec l'oxygène.

Il est évident que l'ajout du chlore dans les réactions d'oxydation se place dans cette deuxième catégorie.

Les résultats bibliographiques sont nombreux et concernent essentiellement l'introduction de petites quantités de chlore dans les réactions d'oxydation [19] et des petites quantités d'oxygène dans les réactions de chloration [20] — sans faire une analyse exhaustive de ces résultats bibliographiques il est possible de faire apparaître deux idées maîtresses sur lesquelles s'accordent ces auteurs :

Premièrement : l'addition d'oxygène dans les réactions radicalaires de chloration inhibe ces dernières.[20,21,22,23]

Deuxièmement : l'addition de chlore dans les réactions d'oxydation en phase gazeuse ou liquide diminue la période d'amorçage et abaisse le seuil thermique de l'oxydation.

Cette généralisation nous paraissait de prime abord surprenante parce qu'il était raisonnable de penser que les résultats dépendaient des appareillages utilisés, de la température, de la *structure* des composés étudiés, des *groupements fonctionnels* et des rapports O_2/Cl_2 mis en jeu...

Les résultats obtenus au laboratoire,[16] confirmaient ces présomptions. Cette généralisation, bien que discutable, avait toutefois le mérite de schématiser des processus complexes. Et, dans la mesure où nous la refusions, il était indispensable de trouver une explication raisonnable et aussi générale que possible à des résultats contradictoires sur les effets compétitifs de l'oxygène et du chore dans les réactions d'oxychloration.

Une réponse, qui va dans le sens de nos résultats, a été apportée récemment par Bizongwako et Huybrechts.[17,18] En effet, ces auteurs ont montré que le caractère « inhibiteur » de l'oxygène dans les réactions radicalaires de chloration dépend étroitement de la stabilité de radicaux peroxydiques formés. Plus particulièrement, ces auteurs ont étudié l'effet de l'oxygène sur les photochlorations en phase gazeuse de l'éthane, des tri et tétrachloréthylènes et du pentachloréthane. Ces études ont fourni de précieux renseignements sur l'effet « inhibiteur » de l'oxygène. En effet, le pentachloréthane, les tri et tétrachloréthylènes ont un comportement fort semblable tant au point de vue de la photochloration influencée par l'oxygène que du point de vue de l'oxydation photosensibilisée par le chlore. Par contre, l'éthane est beaucoup plus sensible à l'effet inhibiteur de l'oxygène lors de la photochloration. Il apparaît ainsi que les différences de comportement observées correspondent aux différentes structures des radicaux intervenant dans ces réactions.

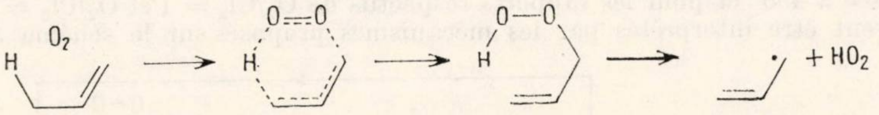
1 — Dans le cas de l'oxychloration du cyclohexène,[6] *nous avions nous-même proposé le mécanisme concerté suivant:*



Un certain nombre de faits expérimentaux semblent corroborer ce genre de mécanisme (cf. réf. 6). En particulier, lorsque l'on analyse, au cours du temps, les produits transformés, on remarque (figure 1) que le pourcentage (chloro-3 cyclohexène + cyclohexénone) par rapport à celui du *trans*-Dichloro-1,2 cyclohexane ne cesse d'augmenter pour se stabiliser vers la sixième heure. Ce résultat est compatible avec le temps d'initiation des réactions d'oxydation (beaucoup plus long que celui des réactions de chloration) et semble indiquer que le radical cyclohexène-3 yle provient de la seule action de l'oxygène sur le cyclohexène.

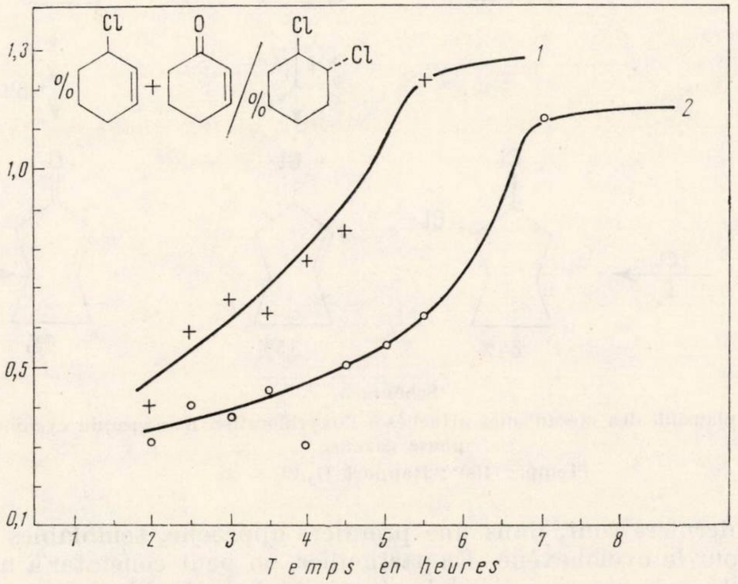


Fig. 1. — *Evolution au cours du temps du rapport* :
(% chloro-3 cyclohexène + % cyclohexénone) / (% *trans*-Dichloro-1,2 cyclohexane).
Courbe *1* : rapport $O_2/Cl_2 = 2$; courbe *2* : rapport $O_2/Cl_2 = 1$.

Ce radical est ensuite piégé soit par le chlore, soit par l'oxygène pour aboutir respectivement au chloro-3 cyclohexène ou à la cyclohexènone conjuguée.

2 — *Mécanismes d'oxychloration du cycloheptène*

Les résultats expérimentaux [24] de l'oxychloration du cycloheptène réalisée à 450° et pour les rapports respectifs de $O_2/Cl_2 = 1$ et $O_2/Cl_2 = 2$ peuvent être interprétés par les mécanismes proposés sur le schéma 3.

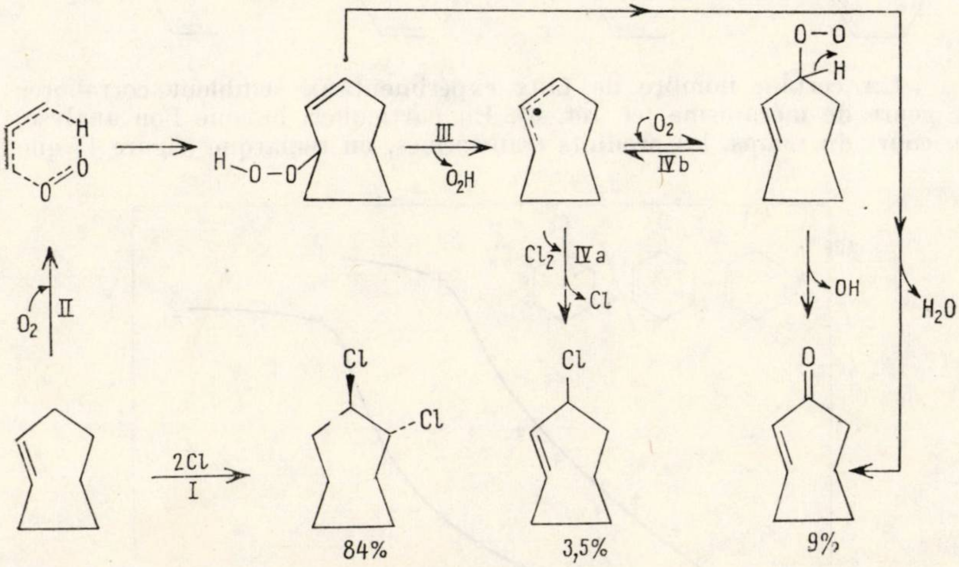

Schéma 3.
Description plausible des mécanismes attachés à l'oxychloration ménagée du cycloheptane en phase gazeuse
(Temp. : 450° ; Rapport $O_2/Cl_2 = 2$)

Ces derniers sont, dans une première approche, semblables à ceux avancés pour le cyclohexène. En particulier, on peut constater à nouveau la sélectivité de la réaction, liée à la réactivité de la double liaison vis-à-vis du chlore, réactivité qui se traduit par l'obtention presque quantitative de *trans*-Dichloro-1,2 cycloheptane. On peut noter là aussi des produits dérivant du radical cycloheptène-2 yle, c'est-à-dire, le chloro-3 cycloheptène et la cycloheptène-2 one. L'apparition de ces composés est liée à la présence de l'oxygène dans le milieu réactionnel. En effet, les pourcentages de ces produits augmentent lorsque le rapport O_2/Cl_2 croît. Comme dans le cas du cyclohexène, l'obtention de chloro-3 cycloheptène et cycloheptène-2 one montre une fois encore la compétition, au niveau du radical cycloheptène-2 yle, du chlore et de l'oxygène. Il faut cependant remarquer les faibles pourcentages des produits dérivant du radical cycloheptène-2 yle comparés à ceux obtenus dans le cas du cyclohexène, ce qui implique une plus faible réactivité de la position en α de la double liaison dans le cas du cycloheptène. On voit là l'influence de la géométrie qui sera développée ultérieurement.

---

[24] A. VERMEGLIO, Thèse de spécialité, Nice, 1971.

3 — *Mécanismes d'oxychloration du cyclopentène*

L'analyse comparée des résultats de la réaction pour les cycloalcènes en C_6 et C_7 laissait apparaître une diminution de la réactivité de la position en α de la double liaison dans le cas du cycloheptène. Cette tendance s'accentue et se cristallise dans le cas du cyclopentène, caractérisé par l'absence de tout produit dérivant du radical allylique : cyclopentène-2 yle. En conséquence, la réaction d'oxychloration du cyclopentène est sélective, la sélectivité se manifestant par l'obtention de 96% de *trans* dichloro-1,2 cyclopentane.

B – INFLUENCE DE LA STRUCTURE SUR LE MÉCANISME D'OXYCHLORATION

Les données bibliographiques accessibles, ainsi que nos propres données expérimentales peuvent nous permettre de répondre à deux questions.

Premièrement : Comment peut-on expliquer les différences qui apparaissent dans la série C_5 à C_7 en ce qui concerne l'attaque en α de la double liaison ?

Deuxièmement : Si ce processus est possible, comment peut-on justifier la répartition entre les produits chlorés et les produits oxydés pour cette position particulière (en α de la double liaison) ?

Nous avions déjà noté les différences, fondamentales semble-t-il sur le plan théorique dans la « série » cyclopentène, cyclohexène, cycloheptène. On remarque (tableau 3) et note à nouveau que l'attaque en α

Tableau 3

Étude comparée de la réactivité de la double liaison et de la position en α de celle-ci

% Alcènes	Pourcentages d'attaque en α de la double liaison	Pourcentages d'attaque du chlore sur la double liaison
	0 %	96 %
	47 %	53 %
	5,5 %	92,5 %

de la double liaison est importante dans le cas du cyclohexène, beaucoup plus faible dans celui du cycloheptène, et inexistante en ce qui concerne le cyclopentène.

Ces différences montrent que la formation du radical allylique, lorsqu'elle est possible, ne correspond pas à un simple arrachement de l'hydrogène en α de la double liaison par l'oxygène selon la réaction : $(-CH_2-CH{=}CH- + O_2 \rightarrow -\underset{\cdots\cdots}{CH-CH-CH}- + .O_2H)$. On comprend mal, en effet, l'influence de la structure si l'on admet un tel processus.

Schéma 4.

Interactions de non liaison associées :

- aux molécules de cyclohexène et cycloheptène
- aux radicaux cyclohexène-2 yle et cycloheptène-2 yle

Ainsi le mécanisme avancé dans le cas du cyclohexène, pour justifier la formation du radical cyclohexène-2 yle et suivant lequel l'oxygène réagissait par un processus concerté à six centres, prend, à nos yeux, plus de poids. Il est possible, dès lors, de justifier les différences qui apparaissent dans l'oxychloration de la série des cycloalcènes en C_5, C_6, C_7.

En effet, pour qu'un tel mécanisme puisse avoir lieu entre l'oxygène moléculaire et l'alcène, il est nécessaire que les liaisons C—H des hydrogènes vicinaux à la double liaison puissent se placer parallèlement aux orbitales π de cette dernière.[25,26,27,28]

On comprend, dans ces conditions, qu'il n'y ait pas de produits dérivant d'une attaque en α dans le cas du C_5 (cycle rigide).

De plus, le schéma 4 permet d'expliquer les différences notables de pourcentages d'attaque en α entre le cyclohexène et le cycloheptène. En effet, si l'on considère ces deux molécules dans la conformation permettant un mécanisme concerté, on constate que les interactions entre les hydrogènes 4 et 6 (du cyclohexène) sont nettement plus faibles que celles qui existent entre les hydrogènes 4 et 7 (du cycloheptène).

La conformation impliquant un mécanisme concerté pour le cyclohexène est donc plus favorisée que celle du cycloheptène.

Ainsi l'addition du chlore sur la double liaison, plus importante dans le cas du cycloheptène et du cyclopentène que dans celui du cyclohexène, ne paraît pas devoir être attribuée à une réactivité spéciale de la double liaison, mais plutôt au manque de réactivité des hydrogènes en α de celle-ci.

C — RÉPARTITION DES PRODUITS CHLORÉS ET OXYDÉS

Le problème de la répartition des produits chlorés et oxydés à partir d'un radical peut être posé d'une manière explicite à travers les trois séries de réactions concernant l'oxychloration du cyclohexane, * du cyclohexène et du cycloheptène réalisées au laboratoire.[24]

— On constate que, dans le cas de l'oxychloration du cyclohexane,[11] la compétition entre le chlore et l'oxygène vis-à-vis du radical cyclohexyle se traduit par l'absence de monochlorocyclohexane. La formation de dérivé monochloré est donc inhibée par la présence d'oxygène, et il est important de remarquer que de nombreux auteurs [21 à 23] systématisent ce type d'inhibition.

— Deuxièmement, en ce qui concerne les résultats obtenus pour le cyclohexène et le cycloheptène, on peut noter, d'une part, l'apparition de produits monochlorés, d'autre part, signaler que les pourcentages des produits oxydés dans le cas du cycloheptène sont supérieurs à ceux des produits chlorés, alors que la situation est inversée pour le cyclohexène.

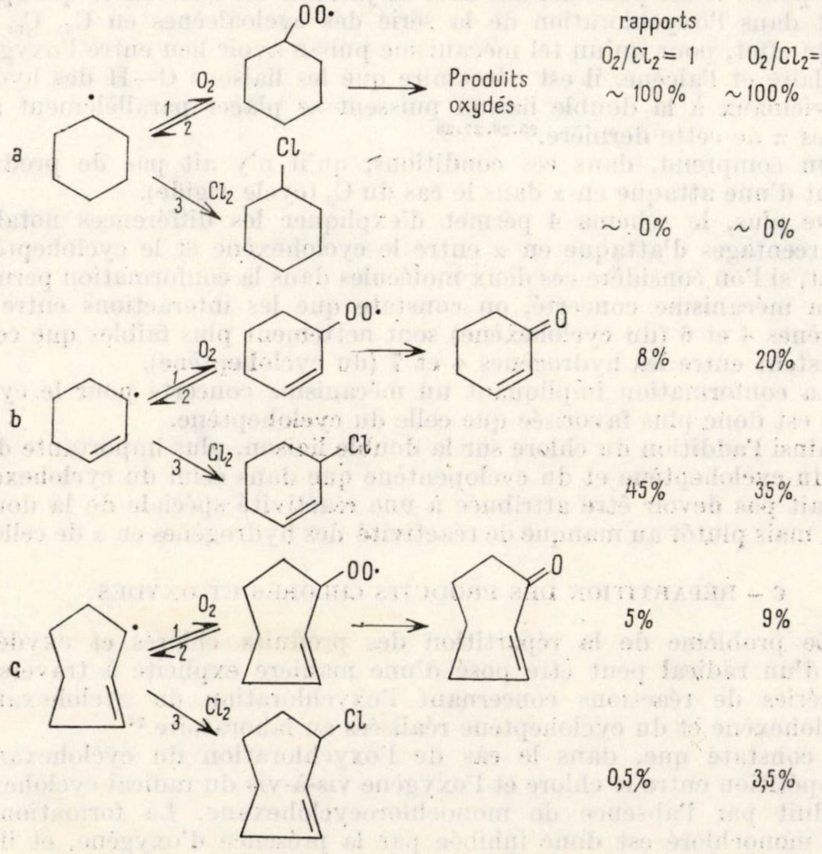
Remarquons que l'oxychloration du cyclohexène conduit à près de 45% de chloro-3 cyclohexène.

---

[25] N. A. Khan, *J. Chem. Phys.*, **22**, 2090 (1954).
[26] N. A. Khan, *Canad. J. Chem.*, **32**, 1149 (1954).
[27] E. H. Farmer, *Trans. Faraday Soc.*, **42**, 228 (1946).
[28] K. U. Ingold, *Chem. Rev.*, **61**, 563 (1961).

* Les résultats sont très semblables dans le cas du cyclopentane et du cycloheptane.

Ces résultats, déroutants à première vue, mettent toutefois en évidence le fait que l'oxygène n'est pas nécessairement un inhibiteur ; ils s'insèrent d'ailleurs parfaitement dans l'ensemble développé ci-dessous.



Pour expliquer les données contradictoires qui résultent de la compétition entre le chlore et l'oxygène, il faut semble-t-il, tenir compte de la stabilité des radicaux alkoyles obtenus. Dans le cas du cyclohexane (a), l'équilibre est déplacé dans le sens 1 car le radical cyclohexyle est peu stable. Par contre, les radicaux allylique cyclohexène-2 yle et cycloheptène-2 yle étant relativement stables, la réaction R. + $O_2 \underset{2}{\overset{1}{\rightleftharpoons}} RO_2$. (b et c) n'est que partielle. Il s'ensuit une accumulation de ces deux radicaux allyliques, évacués sous forme de chloro-3 cycloalcènes, selon la réaction R. + Cl → RCl.

Pour justifier la différence de pourcentages des produits monochlorés et oxydés dans les cas respectifs du cyclohexène et du cycloheptène, il suffit de noter la différence de stabilité des deux types de radicaux allyliques : le radical cycloheptène-2 yle étant moins stable que son homologue inférieur du fait des interactions de non-liaison. L'équilibre $R. + O_2 \underset{2}{\overset{1}{\rightleftharpoons}} ROO.$

est, de ce fait, plus fortement déplacé dans le sens 2 dans le cas du cyclohexène que dans celui du cycloheptène. Les travaux de Bizongwako [17] et Huybrechts [18] confirment ce point de vue. En effet, ces auteurs ont réalisé la photooxychloration des dérivés chlorés de l'éthane et ont montré que la fixation de l'atome de chlore ou de l'oxygène sur les radicaux dépendait étroitement de leur stabilité. Le radical éthyle, en présence de chlore et d'oxygène, conduit essentiellement aux produits oxydés, tandis que le radical plus stable dérivant du pentachloréthane réagit essentiellement avec le chlore.

CONCLUSION

L'analyse des résultats de la chloration des cyclopentène, cyclohexène et cycloheptène à 250° et 450° (pour un rapport alcènes/$Cl_2=14$) et de ceux de l'oxychloration en phase vapeur de ces mêmes hydrocarbures nous a permis de mettre en relief un certain nombre de points fondamentaux consignés ci-dessous :

— Le phénomène de chloration :

Les réactions de chloration, dans nos conditions expérimentales, se traduisent par l'obtention presque quantitative de *trans*-Dichloro-1,2 cycloalcanes (respectivement 90 %, 85 %, 90 % pour le C_5H_8, C_6H_{10}, C_7H_{12}). Cette stéréospécificité peut être aisément justifiées par une attaque en deux étapes de la double liaison de l'alcène par le chlore radicalaire.

— Le phénomène d'oxychloration :

Nous avons pu mettre en évidence les réactivités différentes de l'oxygène et du chlore vis-à-vis de l'alcène : elles se manifestent par l'obtention de cyclénones, de chloro-3 cycloalcènes et de *trans*-Dichloro 1,2 cycloalcanes. En effet, l'oxygène est à l'origine du radical allylique vraisemblablement par un mécanisme concerté à six centres, tandis que le chlore se fixe préférentiellement sur la double liaison ou en α de celle-ci si le radical allylique est initialement formé par l'action de l'oxygène.

— Influence de la structure :

Dans le cas de la chloration, l'influence de la structure se traduit à travers l'absence ou l'obtention de *cis*-Dichloro-1,2 cycloalcanes. Plus particulièrement, l'absence de *cis*-Dichloro-1,2 cyclopentane permet d'exclure un mécanisme impliquant une attaque du chlore moléculaire sur la double liaison.

En ce qui concerne l'oxychloration, les différences notables, observées dans les séries C_5, C_6 et C_7, concernent en particulier l'attaque en α de la double liaison par l'oxygène et la répartition entre les produits chlorés et oxydés pour cette position particulière. Ces différences corroborent l'hypothèse d'un processus concerté à six centres entre l'oxygène et l'alcène. Celui-ci permet en outre de mieux comprendre la répartition entre produits oxydés et chlorés, répartition liée à la stabilité des radicaux allyliques formés. Ces résultats soulignent le caractère gratuit d'une généralisation de l'effet inhibiteur de l'oxygène sur les réactions radicalaires de chloration. Il est clair que la compétition du chlore et de l'oxygène dépend du substrat qui leur est offert, et plus particulièrement de la stabilité des radicaux intermédiaires.

Revue Roumaine de Chimie, **18**, *6*, 995–1004 (1973)

USE OF ESR SPECTRUM SIMULATOR FOR DETERMINING PRECISELY HYPERFINE COUPLING CONSTANTS OF STABLE NITROGEN FREE RADICALS

N. NEGOIȚĂ, R. BAICAN, F. DOMȘA and A. T. BALABAN

Institute of Atomic Physics, P.O. Box 35, Bucharest, Romania

Received February 14, 1973

By means of an ESR spectrum simulator, the hyperfine coupling constants of arenesulphonyl-phenyl-nitroxides (I), aryl-nitroso-nitroxides (II–IV) and 1-benzenesulphonyl-2,2-diphenylhydrazyl (V) were determined with a precision of ±0.05 Gauss.

In a preceding paper,[1] a method was described for determining in a first order approximation isotropic hyperfine coupling constants of organic stable free radicals in solution from experimentally obtained electron spin resonance (ESR) spectra. Even though this method was expanded into a computer program,[2] it is limited by the assumption that coupling constants are integer multiples of a smallest unit. To overcome this limitation either a spectrum simulator, or a more complex program [3] must be employed. The present paper exemplifies the former alternative.

The factors which limit the precision of data determined from an ESR spectrum depend on the ESR spectrometer and on the sample. Among these factors, the most important are the following ones :[4–9]

— limited sensitivity of the spectrometer ;

— non-linearity of the static magnetic field in the sweeped range ;

— non-optimized amplitude of the magnetic field modulating the static magnetic field ;

— distortions induced by the sweep rate, attenuation and other recording conditions ;

— instability of the free radical;

— polarity of the solvent, influencing the quality factor of the cavity;

— paramagnetic impurities in the solution, including oxygen left by an incomplete degassing of the sample;

— interactions with other paramagnetic centres owing to the finite dilution of the solution.

Nevertheless, even under standard conditions without special precautions, data concerning the g-factor, the spin-spin relaxation time, line widths and hyperfine coupling constants cover a wide informational area which characterizes completely a free radical. The last two parameters can be determined with a high precision by employing an ESR spectrum simulator.

Free radicals whose odd electron interacts with more than two non-equivalent nuclear spins have a fairly large number of lines which are usually partly overlapped. Therefore the number and intensities of peaks do not allow a straightforward determination of hyperfine coupling constants. Rather, an assumed set of coupling constants and line widths is used to simulate an ESR spectrum which is then visually compared with the experimental one.

In the present paper the coupling constants of five free radicals are determined with a precision of ±0.05 Gauss using a SPECTROSYSTEM-100 data processing system consisting of a VARIAN Data 620/i computer connected ON-LINE with an ESR VARIAN E-12 spectrometer. The block scheme of the data processing system is represented in figure 1.[10]

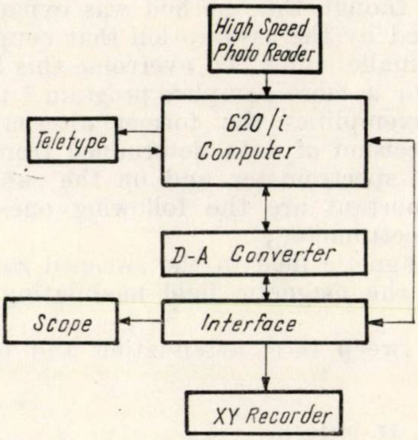

Fig. 1. — Block scheme of the data processing system.

EXPERIMENTAL

The simulation is carried out on the basis of a standard program provided by the producer, through which the following parameters of the ESR spectrum are controlled:

1) range of magnetic field over which the spectrum extends, having a maximum extension of 1000 Gs;

---

[10] Prospect SPECTROSYSTEM 100 VARIAN.

2) position of spectrum on this range;

3) total number of interacting non-equivalent nuclei (i.e., coupling constants); limited to seven;

4) number of equivalent nuclei (i.e. possessing the same coupling constant); limited to 19;

5) nuclear spins;

6) shape of lines, assumed to be linear combinations of purely lorentzian and purely gaussian line shapes;

7) line width calculation is based on

Lorentzian line = $(\sqrt{3}/2)\ \Delta H$

Gaussian line = $(\sqrt{2 \ln 2/2})\ \Delta H$

where H is the peak-to-peak first-derivative linewidth.

8) coupling constants;

9) oscilloscope display, recorder operation for graphical representation, or punched tape output.

The program contains routines allowing the pairwise combination of three spectra from the three buffers.

ESR spectra of the five free radicals which are either nitroxides (aminyloxides), or hydrazyls with an acceptor and a donor group attached to the nitrogen atom,[11] were experimentally determined with the VARIAN E–12 spectrometer at room temperature and recorded graphically. From these spectra, the magnetic field range, line widths, numbers, and positions of lines were measured. First-order approximations for coupling constants and relative intensities were determined as described previously.[1,2]

RESULTS AND DISCUSSION

On the basis of the program, and ESR spectrum is computed and stored in the memory using a first-order approximation for calculating line positions. The first step consists in generating a list of line positions and relative intensities. Starting from one line of unit intensity in position zero each set of n equivalent nuclei of nuclear spin I_x coupled with the unpaired electron splits this line into $2nI_x + 1$ lines with a spacing equal to the coupling constant a_x, and so on for every other set.

Comparing the experimental spectrum with the simulated one, line widths and coupling constants are modified in order to result in a new simulated spectrum matching more closely the experimental one. Especially relative peak intensities are very sensitive to small variations of these two parameters.

I. *Arenesulphonyl-phenyl-nitroxides* * (*I*) (Ar = phenyl, *p*-tolyl or *p*-bromophenyl) afford practically identical ESR spectra with 27 lines grouped in three components of nine lines each.[12] A first-order approximation yields the following coupling constants

$$a_N = 11.5 \text{ Gauss};\ a_{o,p-H} = 1.48 \text{ Gs};\ a_{m-H} = 0.74 \text{ Gs}$$

* Nitroxides are more correctly named aminyloxides.

assuming the *meta*-hydrogens to have coupling constants half as large as the other phenyl protons, and the arenesulphonyl protons to have unresolved couplings. The component of a triplet should therefore have the following line intensities : 1 : 2 : 4 : 6 : 6 : 6 : 4 : 2 : 1. Actually the central line is weaker (fig. 2) and this is due to the fact that the ratio $a_{o,p-H}/a_{m-H}$ is not exactly 2. Since a_N and a_{m-H} can be measured directly from the spectrum (as the distance between components of the triplet, and the leftmost interval within a triplet, respectively), $a_{o,p-H}$ was varied systematically until with the value 1.68 Gs the simulated spectrum matched the experimental one (fig. 2). The components of the triplet in the experimental spectrum are unequal because the radical decomposes partly during the recording of the spectrum.

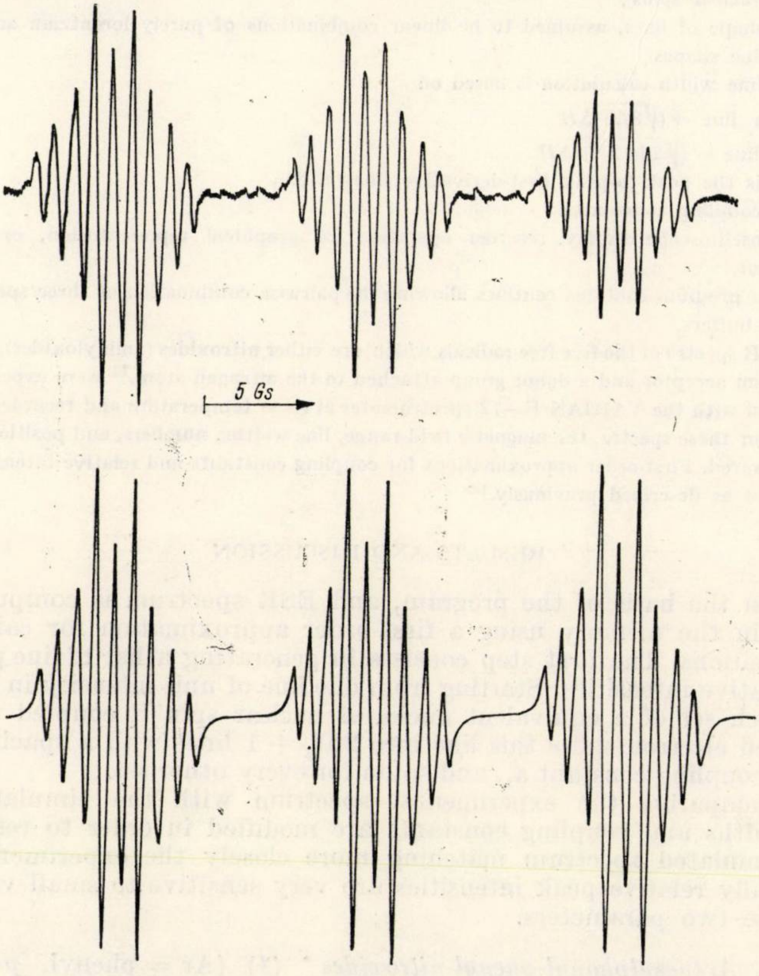

Fig. 2. — Experimental (in 1,4-dioxane) and simulated ESR spectra of benzenesulphonyl-phenyl-aminyloxide (I). Scan time : 3 minutes.

In the next cases, more than one variable must be modified in the search.

II. *N-Nitroso-N-phenyl-nitroxide* (II) was obtained by three independent reactions: decomposition of the preceding radical (I),[12] oxidation of cupferron or of N-nitroso-N-phenylhydroxylamine,[13,14] and spin trapping of nitric oxide by nitrosobenzene.[13] The ESR spectrum was analyzed[1] and yielded the following first-approximation coupling constants listed in the first part of table 1. The large a_{N-O} coupling constant can be measured directly on the spectrum, leaving three coupling constants to be varied systematically. We have chosen to leave unchanged the intermediate coupling constant which corresponds to the *ortho* and *para* protons of the phenyl ring, and to test the effect of varying the other two constants. The result (table 1 and figure 3) is a fairly good matching of experimental and simulated spectra.

Table 1

Coupling constants (in Gauss) used for simulating ESR spectra of nitroxides

Radical	Initial values (ref. 1)						Best values obtained in simulation					
	a_{N-O}	$a_{N=O}$	a_{o-H}	a_{p-H}	a_{m-H}	$\Delta H_{1/2}$	a_{N-O}	$a_{N=O}$	a_{o-H}	a_{p-H}	a_{m-H}	$\Delta H_{1/2}$
I	11.5	—	1.48	1.48	0.74	0.5	11.5	—	1.68	1.68	0.74	0.30
II	10.34	3.74	2.8	2.8	0.95	0.5	10.34	3.78	2.80	2.80	1.98	0.45
III	10.2	3.7	2.8	2.8 (3H)	0.93	0.5	10.20	3.80	2.80	2.95 (3H)	0.88	0.48
IV	10.3	3.43	3.43	—	0.5	1.2	10.30	3.43	2.30	—	0.50	1.00

III. *N-Nitroso-N-p-tolyl-nitroxide* (*III*), i.e. the *p*-methyl homologue of the preceding radical, gives an ESR spectrum presenting 48 peaks which were analyzed in terms of four coupling constants[1,14] (the proton coupling constants for the *ortho* phenyl protons and the *p*-methyl group having the same value).[1,14] Proceeding similarly to the preceding case, i.e. leaving unchanged the large a_{N-O} constant and the a_H constant for the *ortho* phenyl protons, the remaining three coupling constants were varied systematically affording the results presented in table 1 and figure 4. The *ortho*-hydrogens and the *para*-methyl hydrogens no longer appear to have the same coupling constant.
